In Tables 8 and 9 are given respectively, tabulated statements of "ocular reflexes" and "reflex neuroses of possible ocular origin" occurring in the 869 cases of refraction which this paper includes That Table 8 shows a total of 1,467 cases is explained by the fact that two or more of the symptoms frequently occurred in the same individual Distress from reflected light I find to be the most common ocular reflex complained of, while aching or pain in the eye was not infrequently mentioned, and blepharospasm and blepharitis were quite common There were ninety seven cases of marked conjunctivitis and seventy eight cases of excessive lacrymation Of the symptoms in the reflex neuroses of *possible* ocular origin, I can only say I have emphasized possible, and will only add that they existed singly, in pairs and sometimes *in toto*, but to say that they all arose from eye strain is far beyond my desire That many of them were of ocular origin I have but little doubt, and this is especially so in regard to the headaches which existed in 527 cases, about 60 per cent of the patients All headaches are not of ocular origin, errors of refraction uncorrected do not always produce headaches, but having found an error of refraction with headaches, especially of the fronto-temporal variety, following the use of the eyes, we have not room to doubt the wisdom of correcting the error The variety of headache finds its classification in Table 10 The fronto temporal is by far the most common variety, occurring in 40 per cent of all headaches Frontal, becoming occipital, is found in 16 per cent of the headaches complained of and the primary occipital occurs in 11 per cent of the cases

It will be noted that reflected light forms a very large percentage of complaints among the ocular reflexes This is without doubt a greater factor with us in Southern California than in the other parts of the United States, accounted for solely by the fact that we have very white roads and streets, accompanied by about three hundred bright sunshiny days each year When correction of the error of refraction fails to relieve this distressing symptom, I have found that greater relief is given by light blue than London smoked glasses

SYMMETRICAL AND ASYMMETRICAL MERIDIANS OF THE CORNEA IN ASTIGMATIC EYES

[illegible] Ophthalmology, at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md, May 7-10 1895

BY S D RISLEY, M D, AND JAMES THORINGTON, M D
PHILADELPHIA PA

Much practical interest attaches to the symmetrical and asymmetrical direction of the principal meridians of corneal curvature in astigmatic eyes My attention has been directed anew to the subject by the interesting papers of Drs Knapp and Harlan, (Trans Am Oph Soc 1891) and by some recent studies of my own on the relation of asymmetrical meridians in the cornea and different grades of refraction error in the two eyes, to cases of abnormality of ocular balance (*University Medical Magazine*, January, 1895) That these asymmetrical conditions give rise to the more severe forms of asthenopia can not be questioned I have repeatedly brought forward statistics to show that emmetropia must be regarded as the standard refraction for the model eye, since emmetropic eyes and those which most nearly approximate this ideal state of refraction, bear the requirements of civilized life with a minimum of discomfort or peril If this is true, eyes which do not conform to this standard are to be regarded as anatomically defective It is a curious fact that these congenitally defective eyes should in so large a percentage of cases seem to fall under the operation of some law of symmetry It has long been observed that in a large percentage of astigmatic eyes the meridian of shortest radius for each eye is either directly vertical, i e, 90° from a horizontal line, or symmetrically disposed to the vertical axis of the body Knapp found this to be the case in 84 per cent and Harlan in 70 14 per cent This fact awakens the most interesting inquiry regarding the anatomic conditions which determine it and also as to those which give rise to the very frequent variations Any satisfactory answer, however, to such inquiries is extremely difficult to obtain

Observations of certain anomalous conditions which obtain in cases of anisometropia with high grades of asymmetrical astigmatism seem to justify the belief that the form of the eyeballs is in great measure determined by the size of the bony orbits, and that the orbits are in turn modified in their various diameters by the abnormalities in the form of the skull It is obviously difficult to secure the required data as to the form of the eyeballs in any given series and to subsequently measure the diameters of the orbits in the same individuals, but, a cursory inspection of a small number of dried skulls has shown me great variation in the measurements of the diameters of the orbits, that these variations were only a part of certain well defined deformities in the diameters of the skull, and that the abnormalities in the orbits were associated with anomalous conditions in the bones of the face and nasal fossa The purpose of the present study is to show to what extent these anomalous forms find expression in asymmetrical conditions in the direction of the principal meridians of curvature as expressed in astigmatic eyes The present paper presents but one phase of the subject I have observed in a number of patients presenting a wide difference of refraction in the two eyes, with high astigmatism in one and much lower in the other, and with asymmetrical meridians, that the condition was associated with a well marked difference in the two sides of the face In a few instances the general deformity of the skull could be demonstrated by the hatter's form While the relation between these conditions and the ocular anomaly may seem quite obvious in marked cases of deformity, it is more difficult to demonstrate any association in minor degrees of error, nevertheless they suggest not only the probable etiology of the astigmatic eye and its asymmetries, but also the probable origin of many cases of absolute abnormality in the ocular balance

The following tables are based upon the analysis of 2,500 pairs of defective eyes, 1 300 from the records in my private case-books and 1,200 from the Wills Hospital records In both the cases were taken without selection in the reverse order of application for treatment The corrections were all made with the eyes under the full influence of a cycloplegic, the design being to ascertain as accurately as possible the static refraction of each eye in every case To this end the ultimate test was the subjective examination, but this was, almost without exception, aided by the employment of the ophthalmometer of Javal and Schiotz, and the shadow test, one or both In the private records, in a large number of cases both were used, while in the hospital cases the shadow test was employed in almost every case The two records are kept separate in the tables to show the importance of great care in determining the refraction of the eyes In the haste which it is necessary to observe in the crowded clinic room where a limited time only can be devoted to the correction of a large number of patients, it is not possible to give the painstaking care that is given during the longer time devoted to work in the private office The result of this greater care, to absolutely reduce every eye to the optical basis of emmetropia, is shown by the different results reached Then in the public service it was not always deemed necessary to correct the eyes of those employed in coarse labor, with the same accuracy as would be observed in the case of those engaged in finer pursuits

The analysis discloses the percentage of simple myopia and hypermetropia, of monocular and binocular astigmatism In the latter group the symmetrical and asymmetrical direction of the meridians of shortest radius were carefully noted The result is disclosed in the condensed tables, which have been prepared with great care by Dr Thorington

All cases are grouped as symmetrical, where the combined value of the inclination of the meridians was 180° of linear development on an arc, counting from 0° on a horizontal line Thus, if the meridian of shortest radius was at 90° in both eyes, or at 60° on one side and 120° on the other, or at 75° and 105° respectively, they were recorded as symmetrical, since the sum of their values is in each case 180°, and so for any other inclination, e g , 0° and 180° or 15° and 165°, and so on These symmetrical inclinations are divided into those according to rule (homologous astigmatism), i e , where the shortest radius was at 90° or approximately so, and those against the rule (heterologous), that is to say where the shortest radius was found at 0° or approximated the horizontal nearer than the vertical direction The asymmetrical cases were also grouped according as the direction of the meridians approximated the vertical or horizontal direction All cases where the combined values in degrees were greater or less than 180° are placed in the asymmetrical groups unless the meridians were at right angles They were then placed in the group of heteronymous astigmatism In the rare instances where the meridians were inclined from the vertical or horizontal, but were parallel to each other, they have been placed under the head of homonymous astigmatism For example, if the axis of the correcting cylinder were required at 90° on one side and 75° or 60° on the other, it will be found under the head of asymmetrical astigmatism according to rule If the axis was placed at 0° and 150°, respectively, it was placed under asymmetrical astigmatism against the rule If at 0° and 90° respectively, the case fell under the category of heteronymous, whereas if both axes were required, for example, at 60° or at 120°, it was recorded as homonymous astigmatism

SUMMARY OF REFRACTION ERRORS AND DIRECTION OF MERIDIANS OF SHORTEST RADIUS IN 2 500 PAIRS OF EYES—1,800 IN PRIVATE—1,200 IN HOSPITAL RECORDS

	Private		Hospital	
Simple myopia	7	5%	25	2 0%
Simple hypermetropia	72	6 0	253	21 0
Monocular astigmatism	70	5 0	94	7 8

LATENT ASTIGMATISM

Read in the Section on Ophthalmology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY HORACE M STARKEY, M D

CHICAGO

For a number of years the conviction has been deepening in the mind of the writer that latent astigmatism plays a much more important role in the production of asthenopia than is usually supposed, if one may judge from the attention given to this subject in text-books and monographs This conviction has been more decided, since it has become more common to give patients lenses correcting the apparent error, to be worn continuously for one or more days, after which another test of the refraction is made

Some of the members of this Section may remember that the writer one year ago mentioned with praise the practice, common with some ophthalmologists, of giving lenses, not only spheres but cylinders, to patients to be worn a few days for trial before writing the prescription for permanent glasses Again, your attention is called to this procedure with the certainty that no one of you who may employ it will willingly discontinue a plan so satisfactory both to physician and patient For convenience, the oculist must provide himself with a number of pairs of light spectacle frames, of various dimensions and differing in no way from ordinary spectacle frames except that the cells must be round instead of oblong, so that cylinders and prisms may be rotated in any direction With a supply of lenses ground to fit these frames the oculist can, in a moment, adjust almost any combination It is all very well to say that a cycloplegic must be used in every case and that full correction of the error thus found must be prescribed But often this is absolutely impracticable Many patients will not submit, but will go to the optician and take whatever he may offer, rather than subject themselves to the action of even the most evanescent of the cycloplegics Many of the busy men and women in banks, stores and schools who most need skilled services, are willing to take half an hour or an hour a day for a week or two if necessary, but absolutely refuse to give up the whole of one or more days While not ideal this method has much to commend it and leads to correct results Not the least point in its favor is the fact that it keeps the patient comfortable from the first, which with the nervous, the irritable and the skeptical is no small matter Since proceeding in this way with many cases, the frequency with which latent astigmatism is a very important factor in the causation of asthenopia has been forced upon the writer's attention as never before And this because it presents a much more vivid object lesson, when one works out the refraction as carefully as possible with the ophthalmoscope, the retinoscope and the test lenses, gives a cylinder which seems to correct the error and finds, when the patient returns in one or two days, the former amount of manifest astigmatism doubled and after a further time, that a still higher degree of astigmatism has become manifest This method presents a much more vivid object lesson than the correction of the same error under a cycloplegic These object lessons became so frequent that they could not be ignored and led to a reexamination of the text-books on ophthalmology to learn the teaching of the authorities on this point This teaching, as shown by twelve recent works, may be briefly summarized as follows in the following, De Schweinitz 1892, Juler 1893, Norris and Oliver 1893, and Kies 1895 nothing on this topic could be found

Nettleship, "Diseases of the Eye," 4th American Edition, 1890, page 354, has the following "There seems no doubt that in young persons with vigorous accommodation, the astigmatism of the cornea is often partly corrected by the ciliary muscle acting unequally on the different meridians of the lens and that the seemingly greater frequency of astigmatism in the presbyopic is due to the impairment of this power

Schmidt Rimpler (Roosa) 1889, "Ophthalmology and Ophthalmoscopy," pp 82, 83 says "Differences in the meridional curvature of the lens occur occasionally from partial contraction of the ciliary muscle and, if situated in the opposite direction, serve to diminish the corneal astigmatism" "In rare cases, astigmatism depends solely on anomalies in the curvature of the lens and disappears after the use of atropin" And again, page 88 "In all these tests the results are often disturbed and confused by partial contraction of the ciliary muscle, which as we have mentioned may cause diminution, and even abolition of the astigmatic error of refraction The use of atropin relieves this difficulty, but it is to be noted that the correcting lenses which are then found, are often discarded by the patient on the restoration of accommodation"

From 'Errors of Refraction,' Valk, 1890, page 158 'Let me caution you at this point that you may meet cases of astigmatism that will be concealed or caused by irregular contraction of the ciliary muscle thus changing the refraction of the lens in different meridians This condition you will discover by the action of atropin, and by the ophthalmoscope" He also gives several examples among the "illustrative cases,' where astigmatism was made evident or increased by use of atropin

Fuchs 'Text book of Ophthalmology' 1892, p 655 'Another cause of asthenopia lies in the endeavor of the astigmatic patient to correct his astigmatism by means of his accommodation For this to be effected it is necessary that the act of accommodation shall take place with a varying degree of force in the separate meridians of the lens That this can be done is proved by the fact that after atropinization the astigmatism is not infrequently found to be considerably higher than before'

Berry 'Diseases of the Eye, 1893, page 556, teaches that corneal astigmatism according to rule is lessened by lenticular astigmatism while that contrary to rule is increased by the action of the lens

Anomalies of Refraction and of the Muscles of the Eye," Tiffany, 1894, p 208 "Astigmatism is frequently concealed by the power of accommodation, especially in the low degrees In these individual cases as before said, complete mydriasis is imperative that the true conditions may be revealed"

Noyes, "Diseases of the Eye," 1894, p 111 "Astigmatism of the lens may increase or diminish that of the cornea Javal has shown that a small fraction of the total astigmatism is due to the lens, he has also shown that by accommodation the lens may partly or wholly neutralize asymmetry of the cornea He, and before him, Dobrowlsky, attributes this to unequal contraction of the ciliary muscle" "Latent and manifest astigmatism refer to the influence of the accommodation in concealing or modifying the error"

Roosa has considerable to say about the position and shape of the lens as permanently modifying corneal astigmatism, but says little about astigmatism becoming latent Roosa, "Treatise on Diseases of the Eye," 1895, p 497 "The subtraction of half a dioptre," (from the corneal astigmatism as shown by the ophthalmometer) "for the neutralizing action of the lens will generally give, in astigmatism with the rule, the degree that remains for correction, and as Donders stated in 1864, in the English language, the total astigmatism of the dioptric system of the eye "In corneal astigmatism against the rule, the action of the lens does not, (whatever it may be) practically relieve the astigmatism It must then be fully or over-corrected in order to relieve the symptoms"

We find that of these well-known authors, four do not mention the subject, two speak of the lenticular astigmatism as modifying that of the cornea, but do not mention the correcting action of the ciliary muscle, and six show such action as an important and always to be remembered factor In so far as any mention is made of the point, it is taught that the action of the lens only corrects corneal astigmatism when the latter is according to rule The writer's cases, however, show that a portion of the astigmatism may be latent, whether the meridian of greatest curvature is vertical, horizontal or diagonal To illustrate how latent astigmatism may be rendered manifest by the use of cylinders, ten cases seen in private practice during the last four months of 1894 are taken Each of these showed an increase of from 0 25 to 1 D in the manifest astigmatism They were all relieved of severe asthenopia by the use of cylinders and have had no return of the asthenopia in the intervening time, four to eight months (About the same number of similar cases have been seen since Jan 1, 1895) For lack of time but four cases are given in detail

Case 1—Mrs H, stenographer, age 28 Had been unable to work for several months on account of headache from which she has always been a sufferer Apparent astigmatism of 0 37 D according to rule increased by use of glasses two days to 0 62 D, which gave complete relief so that work was resumed Relief has continued to the present time without further increase of astigmatism

Case 2—Mr M, medical student, age 22 Apparent astigmatism of + 0 37 D at 105° and 100° increased to + 0 88 D at same angles

Case 3—Frances I age 13 Apparent astigmatism of + 0 37 D × 90 each eye increased to + 1 D and + 0 88 D × 90

Case 4—Mrs Dr W, age 41 First seen Sept 6 1894 Eyes tire quickly and she has much headache, particularly after going to theater or other places where faces are watched Examination shows astigmatism, which appears to be corrected by + 0 37 D C × 90 each eye, which glasses seeming very restful, are given for use for twenty-four hours September 7 Requires + 0 75 D C × 90 each eye, which were given September 8 Requires + 1 D C × 90 each eye Prescribed + 1 D C × = 90 for each eye These glasses have been worn continuously since with great satisfaction and comfort, though the left eye would now take + 1 25 D C

Case 5—Mrs J F D, age 31 Apparent astigmatism of + 0 62 D and + 0 37 D × 180 increased to + 1 25 D and + 2 D × 180 Subsequent use of cycloplegic showed this to be the total amount of astigmatism

Case 6—Miss C E W, trained nurse, age 29 Has had very severe and almost constant headaches for many years October 2, apparent astigmatism + 0 62 and + 0 50 D × 90, for which lenses were given October 4 accepts + 0 88 and + 0 75 D C × 90 October 5 No headache, though eyes were used much by artificial light at fancy work, etc to try them Likes + 0 88 for each eye, which was given with complete relief

Case 7—Mr J B C, age 24, copyist. Apparent astigmatism of + 0 37 D and 0 25 D contrary to rule increased to + 0 62 and + 0 50 D at same angle

Case 8—Mr R A S, medical student, age 32 Dec 13, 1894 Has worn + 0 50 D C contrary to rule for each eye for about five years Have not seemed right of late Requires now + 1 D C × 15 and + 0 62 D C × 180 These are given December 17 Has used above with much more comfort than former glasses Now requires + 1 25 D C × 15° and + 0 88 × 180, which are tried December 21, likes above very much, so prescribed + 1 25 D C × 15° and + 0 88 × 180, which give entire satisfaction

Case 9—Miss O B , age 31 Dec 12 1894 Apparent astigmatism of right eye corrected by + 0 75 D C > 60 , left eye hyperopic 1 25 D These lenses worn till December 31, when R E requires + 1 50 D C ∖ 60 which is given Jan 3, 1895, R E requires + 1 75 D C ∖ 60 Further astigmatism not developing, + 1 75 D C ∖ 60 and + 1 25 D S were prescribed These have been used with comfort ever since and eyes are used more easily than for many years

Case 10—Mr G H C , age 24 Clerical work Has constant headache and eyes tire easily Appears to require — 0 25 D C / 90 but retinoscopy favors + 0 25 D C × 180 — 0 25 D C ∖ 90 for three days were not comfortable Used + 0 37 D C ∖ 180 three days without headaches and could use eyes much more easily Now finds + 0 50 D C × 180 good, and three days later + 0 62 D C × 180, which were finally given Eyes have since been used without headache or weariness

We see that of these ten cases, four had astigmatism according to rule and a fifth had the angles but 10° and 15° from the vertical , three had astigmatism contrary to rule and one varied but a few degrees from this , one had the very irregular angle of 60° Seven eyes show an increase of 0 25 D in the astigmatism , three show 0 37 D, two 0 50 D , five 0 62 D , one 0 75 D , and one 1 D increase in astigmatism

SUMMARY

1 Latent astigmatism is a frequent and important cause of asthenopia

2 The latent astigmatism may in many cases be made manifest without a cycloplegic and without interfering with the patient's business by giving lenses which correct the manifest error, which may be worn a day or two, when an additional amount of astigmatism will be manifest which may be corrected in the same way, and so on till all the latent trouble is unmasked

3 This may be done without discomfort to the patient, and is therefore advantageous with the skep tical, irritable and nervous

4 Recent text-books do not give this subject the attention its importance deserves

5 Astigmatism may be latent whether the axis of greatest curvature is vertical, horizontal or diagonal

ANOMALIES IN OPHTHALMIC PRACTICE

Read in the Section on Ophthalmology, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY A C CORR, M D
CARLINVILLE ILL.

In presenting this paper I am not proposing to present anything new, but merely to bring in a few topics that, to say the least, are out of the ordinary way in ophthalmic practice, and therefore are entitled to be designated as anomalies

Case 1—*Congenital Interstitial Opaque Infiltration of the Cornea, not Syphilitic nor Cicatricial* Dec 1, 1893, was presented for treatment Anne H a two months old, healthy, well developed child No appearance of disease, past or present, except that both cornea were nearly entirely opaque At once I asked the mother when the baby had sore eyes to which she replied 'Its eyes have not been sore " ' When did you notice this condition of its eyes?" She replied ' When it was ten days old " Has there been any yellow or gummy discharge from the child's eyes?" She replied ' There has not " Had you any leucorrhea or whites before or about the time the child was born?" To which she replied, she had not Do you know what I mean by this discharge of 'whites' or leucorrhea?" She said ' Yes for I had it when my second child was born and it made her eyes sore They were very sore at once and for a long time and it made her eyes white, too, as you can see "

On closer examination of the child's eyes the cornea proved to be smooth and regular in contour lids normal eyes well formed, epithelium of cornea well formed and clear and smooth Irides, hazel brown Immediately below the corneal epithelium there was almost a uniform white opacity R E , the opacity was so thick and uniform that the *pupil could not be seen*, and the *iris but dimly*, to lower and inner part The opacity was thickest in upper and outer part L E , the pupil was visible only from lower and inner side under the opacity that extended from above and outward, where it was entirely opaque This condition was in marked contrast to the eyes of the next older child Minnie, aged 6 years, who had evidently had ophthalmia neonatorum The cornea of her eyes was small and distorted, the surface irregular and not smooth, nor the epithelium well formed The opacity was apparently in the epithelium and subjacent layers The lids showed also signs of the past disease The epithelium of the palpebral conjunctiva was degenerated, thick and cicatricial This child, too, was well grown and healthy

The eldest child, Teana, aged 9 years, was a well formed, well developed child Bright and intelligent, eyes without blemish The teeth and jaws of the two older ones were well formed and normal No history of skin disease was elicited

The father, Fritz H aged 30 years of German parentage, about five feet, five , health good Had never exposed himself out of wedlock so as to acquire syphilis Physical examination revealed no signs of it

Mother, Annie L H , aged 30, medium size, well formed, health good, German parentage Pregnant three times only, and three children as above Never had falling of hair, skin disease, nor cutaneous discolorations Says her husband does not drink, and is attentive to his family They are a neat, clean and tidy family , farmers, living in small town

Dr C W Johnson, of Litchfield, Ill , a well-informed physician, graduate of Jefferson Medical College, in active general practice, saw the patient and after hearing the history said, that it was a great curiosity The merest tentative treatment was prescribed aqua pura, ℥i , acid carbolic, gts i , acid boracic, gr xv Mix with collyria

Sig , put a few drops in each eye three times daily

In the meantime, I addressed a letter to Dr M Thomas, B S , the family physician, a physician personally known to me, of good reputation, in active general practice for ten or more years, who wrote under date of Dec 12, 1893 'I have investigated the matter The child has not had inflamed or sore eyes since its birth I am satisfied it was born as you see it Nor have the parents had syphilis I know them well "

December 15 Mother thinks the eyes are improved, child is developing well in every way, other than condition of eyes Slight lateral nystagmus Treatment same

Jan 19, 1895 Condition of eyes perceptibly improved Pupil can be seen through apex of cornea in L E and through lower and inner part of cornea of R E child enjoys looking at light of lamp or window Nystagmus present Child developing nicely Thickest part of nebula above and to outer side both eyes Ordered collyria continued and a little Pagenstecher oint well but lightly rubbed on outside of lids daily

March 2, 1894 Child doing nicely Developing well , corneal opacity clearing up more perceptibly in both eyes Nystagmus Continued medicine as before

April 13, 1894 Improvement marked, yet not so rapid apparently Treatment same

May 25, 1894 Much improved L E cornea clear except a small area Child developing well Follows objects with eyes and uses its hands with fair accuracy to grasp at objects apparently seen Oint and collyria as before continued

July 20 1894 Corneal opacity improving Pupil of R E clearly seen through apex of cornea Nystagmus less

Sept 7 1894 Corneal condition improving Slight signs of internal strabismus of R E , continued treatment

Dec 14 1894 Now one year and fourteen days under observation, and child one year and two months old Condition of eyes much improved L E , nearly entirely clear R E slight haze below apex of cornea and almost imperceptible over apex of cornea Slightly more decided opacity above as if sclera was slightly advanced on to contour of cornea Nystagmus still perceptible R E strabismic Divergent power normal when L E is covered Has four incisor teeth above and below and two bicuspids just emerg ing in upper jaw Teeth not deformed blackened nor decayed Health good Eats some at table and amuses itself with toys

April 28, 1895 The child has grown and is well developed, walks and amuses itself with playthings, and its vision is apparently good Has many teeth—none decayed, on focal illumination of the left cornea, there is slight nebula of former opacity seen In R, corneal opacity is seen plainly without illumination The apex of the cornea is nearly perfectly clear but there is a ring around the apex of the cornea about 3 mm in diameter that is somewhat more marked, and at upper part of cornea the opacity appears as if the sclera was extended about 1 mm on to the cornea Nystagmus less Squint mostly in R E, but alternating

Case 2—Keratitis Materni Twice Recurring Nov 12, 1892, Mrs E A S presented herself for treatment of her sore eyes, 24 years old married Two children, youngest seven months and nursing Eyes have been sore two months Patient, medium sized, not well nourished, pale and anemic, dark hair and fair complexioned hazel brown eyes Conjunctiva of both eyes hyperemic On right eye the cornea was involved with what seemed to be an unusual variety of keratitis It consisted in a band of brownish red, almost the entire circumference of cornea on inner and lower portion about 1 mm wide loss of epithelium and linear extension of capillary blood vessels from conjunctiva on to the cornea to the extent of the width of the band The cornea was not otherwise hazy, aqueous clear Pupil not sluggish, nor other evidence that iris was involved Photophobia marked in R E and pain and tenderness complained of, mostly in R E The eye was cocainized and the band examined with probe It bled freely on being slightly touched The eyes were washed out freely with boric acid solution Pupil of R E dilated with atropin, yellow oxid oint with atropin applied nightly in the usual way and both eyes washed out with boric acid solution two and three times daily

Nov 2[illegible] 1892 No improvement The band had extended entirely around the cornea and was widened Pupil well dilated and other indications of the medicine having been properly used Conjunctiva of L E much more hyperemic Photophobia increased Being somewhat astonished at the condition, I inquired more closely into the constitutional condition of the patient I found no clue to a specific disorder, but not knowing what else to do I suspended the oint and prescribed pot sol iod, hydrarg chlor corros Take a teaspoonful four times daily

Dec 10, 1892 Condition much the same, certainly not improved Whereas she had before been screening eyes with London smoked coquelles I ordered R E kept bandaged, and in addition to the above, ordered quinia grs xxx, taken in next twenty four hours and quinia grs iij taken every morning at 9 o'clock

Jan 20, 1893 No improvement The band had widened in R E to near 2 mm and same condition had involved nearly the circumference of L E The non-involved surface of both cornea clear, and none of the white infiltration of cornea that usually accompanies keratitis The margins of the band on the cornea were markedly even on both eyes As my astonishment had in nowise abated I ordered the potassio mercuric solution alternated every four hours with dessertspoonfuls of elixir of pyrophosphate of iron and calisaya bark, stopped the quinia and bandage left off, coquelles as before

Jan 28 1893 Much improved, spirits much more hopeful Keratitis much abated Hyperemia of conjunctiva less Photophobia less, appetite good, sleep good Ordered the potassio mercuric solution discontinued and elixir of prophosphate of iron and calisaya bark in dessertspoonfuls regularly every four hours Measured refraction, and ordered full correction of ½ D hyperopia, worn all the time

Feb 27, 1893 Patient about well, only slight traces of trouble left, photophobia gone, doing all her work for family and has continued to nurse child all the time Ordered dose of elixir three times daily and collyria discontinued

March 15, 1893 Patient apparently quite well Almost no signs of past keratitic trouble Ordered elixir taken twice daily, as long as nursing continued April and May saw the patient She remained well

Sept 5, 1894 Patient again presented herself for treatment of eyes Nursing third child, which was born in May, 1894 Eyes became sore in August, two months earlier than before Condition of eyes exactly as before in the beginning Brownish vascular band partly surrounding the R cornea, both conjunctivæ hyperemic, with the addition of a slight redness and abrasion along the margins and tip of the tongue, with the characteristic scalded feeling of stomatitis materni This latter confirmed my notion that led to the prescribing of the elixir of pyrophosphate of iron and calisaya bark, that it was a keratitis caused by the conditions that gave rise to the nursing sore mouth that I had treated often in its purity while in general practice

That sterling remedy which has proved more nearly a specific in stomatitis materni under my observation than anything else, the elixir, as before, was at once ordered in dessert spoonfuls four times daily, with an occasional washout of the conjunctival cul de sacs with the boric acid collyria

October 15 The patient seemed about well The disease had not extended and began to abate within a week after the remedy was taken

November 10 Patient wrote she was well I ordered her to continue the elixir in doses as before, twice daily while nursing I am satisfied she is well of her eye trouble to date

Now you may ask why do I call it keratitis materni? Because it originated as a part of the assemblage of symptoms that characterize that maternal disease of stomatitis and *not* amenable to ordinary treatment of the local eye disease, but readily and perfectly amenable to the constitutional and general treatment useful in the disease known in general and obstetrical practice as stomatitis materni

Case 3—Piece of Orbital Bone Encapsuled in the Globe, two and a half years Choroid not Totally Disorganized July 15, 1892, Mr C R B, presented himself for consultation in reference to the future sight of his right eye which was injured on July 4, by a rocket that did not sky He said he was sitting some distance—forty yards—from the stand where the fire-works were being exhibited and that one rocket, after the fuse was lighted, fell so it flew off horizontally and struck him in the eye There was a deep lacerated wound of the skin just at lower margin of orbit, and tissues generally bruised and discolored The tension of the globe was minus Cornea normal and clear Anterior chamber well formed Pupil slightly dilated Lens normal with a pink reflex No reflex from fundus Eye sightless These facts together with the evident severity of the contusion led me to send the attending physician a note that the eye would be sightless and would better be removed

I saw no more of the case till I was called Jan 8, 1895, to remove the eye At this time there was a deeply sunken and adherent cicatrix at the middle and margin of the lower orbit, lower lid everted, and slight whitish secretion in lower conjunctival cul de-sac Globe shrunken about one-third and only slightly tender Tension minus But little of cornea visible, sclerotic nearly normal in appearance Patient said the globe had been tender by spells, and he had some discomfort about the orbit Bits of bone had been discharged through the skin wound and the nostril had discharged more or less secretion all the time The globe was removed in the ordinary way and without any incident worthy of note Immediately after its removal, I incised the globe and found inside a shrunken opaque lens and some fluid contents, rather clear than opaque, choroid only partially disintegrated and adherent to sclera in places At posterior and lower part near the disk, a hard lump of dense tissue was noted, which rattled under the knife when cut and, by close work, I dissected out the bone you see in the hardened specimen It is about three eighths of an inch long, little more than one sixteenth of an inch in lateral dimensions, slightly irregular in shape and has a smooth notch near its middle as if a margin of a foramen—probably the infra orbital—and had been evidently encapsuled in the interior of the globe since the wound by the rocket, July 4, 1892, two and a half years ago

Case 4—Hemorrhage of the Iris, as a Result of Slight Iridectomy in Cataract Extraction July 29, 1894, Mrs M A T, a lady 65 years old, took her place on the chair for cataract extraction on R E She was prepared in the usual way The first incision was made wholly in the corneal tissue An iridectomy was decided upon because the pupil did not dilate round, but rather oval, vertically, and the cataract was of long standing The iridectomy forceps was introduced and the inner edge of the iris grasped, drawn out and snipped with the scissors so as to just allow of the passage of the lens Not more than one-half of the width of the iris was cut out The instant the iris was cut, the anterior and posterior chambers were filled with blood which could be plainly seen, issuing from the edge of the iris Soon everything in both chambers of the eye was obscured by the blood, and no further progress could be made till the blood was washed out The corneal flap was made to gap, and a moderate jet of mildly borated water was made to enter the chambers from a dental bulb syringe until all blood stains were out of the way, when the operation was terminated and the chambers again cleansed by detergent force of the jet as before No untoward effect followed the hemorrhage, except that there was more of the inflammatory exudate in the gap in the iris This, however, was all absorbed, and after a secondary operation, a month later, the vision was fairly satisfactory Of course such hemorrhage was unexpected, unprepared for, embarrassing and somewhat astonishing The only thing unusual in the appearance of the eye was that one of the superficial conjunctival vessels dipped into the sclera within 2 mm of the sclero-corneal junction just opposite to where the iridectomy was made I do not remember having seen an account of but one such case in the ophthalmic literature that has come under my observation

Case 5—Calcareous Lens, Occluding the Pupil, Becoming Detached, Dislocated and Floating—Iritis—Requiring Removal Nov 21, 1894 T R H , a gentleman about 25 years of age, a mechanic, presented himself for consultation and treatment of right eye He said the white in his eye had gone, and was moving around I recognized the gentleman as one I had observed some time before having the pupil of the right eye occluded as a result of plastic iritis caused by being struck in the eye with a ball when about 16 years old, since which time he had had the ordinary white and undilatable pupil which characterizes an occluded pupil The iris was somewhat discolored as compared with its fellow At this time the 'white" in his eye was gone and was moving around The tension of the globe was minus, but not markedly so, within the past few days the patient had sustained some slight stroke on the eye, so slight as not to attract attention only that he accidentally learned that the "white" in the pupil had been dislocated On close examination of the eye, now, I found a white floating body about three-sixteenths of an inch in dimensions behind the iris, that was sometimes in the anterior and sometimes in the posterior chamber At this date the eye did not show signs of irritation

November 28 Patient presented himself with marked circumcorneal hyperemia and the eye tender I advised no longer hesitation about its removal, to which patient readily acceded, but at this time I could not get the lens dislocated into the anterior chamber So I at once produced homatropin mydriasis and had the patient lean far over with face on hands till the lens came forward into the anterior chamber when eserin was instilled, until the mydriasis was overcome and sufficient myosis was produced to retain it there and the operation was proceeded with But, alas! not with the perfection I had anticipated After the corneal incision the lens would not deliver easily It seemed to hang to the iris I introduced the ordinary iris forceps and grasped the lens a little too far back, being deluded by the media I was looking through, and the unexpected hardness of the body, and it slipped and went over into the posterior chamber So an iridectomy was made and the operation completed in the ordinary way

The result brought a good appearing eye and looks better than it did before when the pupil was occluded with a white spot The eye has no perception of light, and no reflex obtainable from the fundus

I meant to exhibit to you the pure specimen, but am obliged to present it crushed by the postoffice stamp The crushed condition may be better for examination

---

NOTES ON TWO CASES OF LARYNGEAL NEUROSES

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY S K. MERRICK, M D
PROFESSOR OF DISEASES OF THE NOSE THROAT AND CHEST BALTIMORE MEDICAL COLLEGE BALTIMORE MD

Case 1—Mrs O H , widow tall and rather slender age about 63 to 65, native of Baltimore was referred to me by Dr Samuel T Earle of this city is a woman of culture and refinement and has lived in affluence and ease most of her life, but had met with some reverses of fortune some years before, and her physician told me that for years past she had been in poor health and was somewhat of a neurasthenic, but was never hysterical

About three weeks before she came under my care she was seized with an acute laryngitis with aphonia Dr Earle applied the usual remedies, but finding the patient got no better, sent the case to me On examination, the pharynx was highly congested, reddened and hyperesthetic It was with great difficulty after several visits that I got a view of the larynx partly owing to the overhanging epiglottis, but principally on account of the morbid irritability of the pharynx Cocain in this case seemed to have little effect A good view, however, of the larynx about the fourth visit was secured and laryngitis was seen to be present, yet not reddening the cords throughout their entire extent but an image was revealed, showing that I had to deal with a paralysis of the arytenoideus muscle The cords from the thyroid angle to the vocal processes were properly approximated on attempts at phonation, but the characteristic triangular space between this point and the posterior commissure left no room for doubt as to the diagnosis The phonative waste which Von Ziemssem first appropriately called this loss of air in this form of laryngeal paralysis on phonation, was well marked

The treatment at first was directed to the cure of the laryngeal inflammation by means of the usual local sprays, and later, strychnia in increasing doses and electricity were used—the faradic current locally and occasionally generally—for the cure of the neurosis, or stimulation of the recurrent nerve

From February 6 to April 20, the patient came to see me on alternate days, generally, and by this latter date the normal color of the pharynx and larynx had apparently returned and yet the characteristic triangular space, the aphonia and phonative waste were all unchanged I decided now to send the patient to the seaside, she accordingly went to Atlantic City, and remained there several weeks, when she returned and again reported at my office—' no better" The laryngeal image was in *statu quo*

As the inflammation, as far as I could determine was gone from the larynx and not the least improvement in phonation had taken place I was inclined to give an unfavorable prognosis In the meantime local treatment, strychnia and electricity were resumed, and on June 14, six months after the beginning of her aphonia, I sent her to the country for the summer with no better voice than when she came under my care I told her family I feared she would never fully regain the use of her voice In this I was mistaken, about the middle of August she suddenly regained it and it has remained unimpaired up to this time

Was this a case of paresis from acute laryngitis, penetrating into the deeper structures causing pressure on a branch of the recurrent laryngeal (the most usually assigned cause of this neurosis) or was there an hysterical element present also? That the acute cold was the exciting cause there is no doubt whatever, and it is not impossible that continual pressure on the nerve-twig supplying innervation to the arytenoideus, had left the nervous energy so weakened, even after the entire disappearance of the inflammatory thickening, that a prolonged stay in the country was necessary to build up the tone of the entire nervous system before the twig could be excited into activity

Sajous says this form of paralysis occasionally results from hysteria Ingals says it most frequently results from acute or subacute laryngitis

Lennox Browne says this form of paralysis may be seen in acute catarrh and it is a question whether this and some of the temporary paralyses may not be due to inflammation of the small glands which are situated around the terminal branches of the recurrent nerve

Bosworth cites three cases reported by Proust—one due to incipient phthisis, one to hysteria one to catarrhal laryngitis and one by Johnson due to diphtheria He further says that hysteria was the assigned cause in cases reported by Mackenzie Luega, and Duncan and Von Ziemssen has observed a case which followed directly upon cold

This last case is *one* of only *two* mentioned in his (Bosworth s) work as having acute laryngitis as the cause In looking over six authors I found this to be the most commonly assigned cause But I did not find any reference made to the possibility of this dual causation both factors acting at the same time

My case was clearly due to acute laryngitis, but its failure to get well after all laryngoscopic traces of laryngitis had disappeared, and the sudden restoration of the voice months afterward, points to an hysterical etiologic element which greatly delayed recovery Knowing that acute laryngitis ushered in the aphonia my efforts were at first all directed to the cure of the former affection, which yielded completely so far as laryngoscopic appearances could establish this fact, yet failing signally to relieve the aphonia after the very apparent cause had been removed and strychnia and electricity doing no good, I gave an unfavorable prognosis, which naturally distressed the patient and her family not a little Had I suspected that hysteria was a latent etiologic factor, it is very probable I could have restored her voice at any time after the laryngitis disappeared

[illegible] —Mrs D married age about 50, mother of four children consulted me Jan [illegible] I learned that in the previous November she had suddenly lost her voice without any premonitions except the 'rising in her throat of a lump or ball the size of a large marble From this time on, she had been unable to speak except in the whispered voice

The laryngoscope revealed the characteristic laryngeal image of unilateral adductor or recurrent paralysis of the right side On attempted phonation the left cord went beyond the median line and near its fellow but not sufficiently close to produce more than the whispered sound on attempted phonation

The patient was very despondent and often shed tears over what she considered her hopeless condition, and all assurances on my part that she would regain her voice were met by a shake of the head and tears I felt sure of her ultimate recovery and assured both her and her husband, who is a prominent clergyman of this city, that I had no doubt of restoring her voice The husband was easily convinced, but all my assurances failed to produce any impression upon her and in consequence all my remedies—applications sprays, electricity, etc, utterly failed to give relief for you must all agree with me that the case was one of hysterical aphonia

This being the first case of unilateral paralysis, of clearly hysterical origin, that I had ever seen, I was anxious to verify the diagnosis, by curing the case so promptly that no doubt would be left as to its etiology In this I was disappointed as I have before indicated She remained under my care until warm weather, when she was sent to the mountains and after a month or more her voice returned as suddenly as it had disappeared, thus confirming my diagnosis

When she returned to the city in the fall, she came to see me, and a surprise awaited me when I made a laryngoscopic examination I found the right chord still in the cadaveric position and the oblique glottic space and over-riding left arytenoid on phonation (the same image) that of right adductor or recurrent paralysis—only the left chord now came close enough to its fellow for the purposes of phonation She now made known important information, which she had withheld from me, fearing it would influence me, and cause me to give an unfavorable opinion at her first t She told me that seven years before, she had consulted an eminent specialist of this city, who had diagnosised paralysis of the chord and told her she would never get well This had preyed on her mind and she confessed it was the chief cause of her incredulity to all my promises of cure During the seven years and up to November, 1892, (when her voice suddenly left her entirely) she had simply impairment of the voice, but could always use it in ordinary conversation—it had neither gotten better nor worse

The case was now clear—I had to do with a case of hysterical paralysis, engrafted upon a long-standing case of unilateral adductor paralysis As soon as the hysterical element had spent its force, a restoration to the condition induced by unilateral adductor paralysis was effected I had a view of her larynx recently and the laryngeal image is still unchanged Her voice is fairly good for conversational purposes, but when she talks much she feels a tired sense in the muscles of the left side, due to strain on the adductors in carrying the left chord beyond the median line

It may be interesting to cite the opinion of several prominent authors as to the etiology of unilateral adductor paralysis before closing the notes on the case

Sajous, p 366, says "That adductor paralysis, bilateral or unilateral, can be due to pressure on the recurrent laryngeal nerve, without involving the other muscles of the larynx supplied by that nerve, seems to be very doubtful" While Ingals, p 503, says "Unilateral adductor paralysis is caused in most cases by pressure upon the recurrent laryngeal nerve, by aneurysm, tumor of the neck, cancer of the esophagus, etc, and not infrequently by hysteria"

Bosworth, p 665, says "I have never seen a case in which I felt warrranted in making a diagnosis of this form of paralysis" He thinks it extremely difficult to differentiate the affection from unilateral recurrent paralysis

Lennox Browne, quoting Mackenzie, says of unilateral adductor paralysis "This rare condition may be due to chronic toxemia, lead, arsenic, diphtheria, etc, may result from cerebral disease or may be caused by cold, or muscular strain, and is met with after smallpox, in constitutional syphilis and in phthisis'

McBride's edition of 1892, says "Pareses confined to the muscles which close the glottis are usually, if not always, due to functional changes in the nervous system, of which we may consider hysteria as the type' In support of this opinion he cites Semon and Horsley s experiments, where unilateral irritation of the corticular area in the brain, of adductor movements, produced bilateral adduction, but unilateral extirpation of the area produced no effect "Having had access," he says, "through the kindness of Dr Semon, to the manuscript of the work (then in preparation) I feel inclined to doubt whether any incontestable evidence can be brought forward as to the existence of laryngeal paralysis, due to organic changes affecting the adductors alone" He further says "From the experiments of Semon and Horsley, it is extremely doubtful whether there is any organic lesion which can produce unilateral paralysis of adduction"

It seems to me that my case, if it proves anything, proves that there was an organic lesion acting for seven years, when a functional disturbance was engrafted and that the cure of the latter had no appreciable effect upon the former This tells against

Semon and Horsley's experiments, as interpreted by McBride, and rather supports the older etiology

A singular and interesting fact in connection with the recovery of the voice in this case, I learned recently, and I mention it because I have never seen *any reference to the like in literature*

When she regained her voice it surprised her as much as it did her auditors As she expected to speak in a whisper as had been her wont for eight months, she was greatly frightened at the sound of her own voice, sent for her husband and in the midst of tears told him that she knew she was going to die—that this was a token Her husband laughed her fears away, telling her the doctor had told her she would again be able to talk Now comes the interesting phenomenon after having conversed in a whisper for eight months, on recovery of her voice, it was *impossible* for her to whisper She tried repeatedly, but each effort to whisper resulted in distinct phonation and clearly articulate speech

The conclusions which, I think, clearly follow from the notes on the above cases are

1 That we may have a paralysis of the arytenoideus muscle, due to the most usual cause, viz , acute cold, recover suddenly—just as hysterical cases recover—hysteria being a probable factor delaying recovery

2 That we may have hysterical aphonia supervene upon an old case of unilateral adductor paralysis, where only weakness of the voice was present, leaving the voice only slightly impaired from the old lesion, the latter being still in force and unaltered as shown by the laryngeal image

3 That authors differ widely as to the etiology and even existence of unilateral adductor paralysis, and that this field is a legitimate one for investigation, if for no other reason for the sake of rational and in consequence more successful therapeusis

4 That as long as diametrically opposite views are held by such authors as I have quoted, concerning its etiology, students will be confused rather than taught by the multitude of contradictory statements

5 That the greatest care should be taken before making a positive diagnosis in all cases of neuroses of the larynx, as the chances of error are numerous, and downright mistakes harmful in many ways

843 North Eutaw Street

HISTORY OF A CASE OF RECURRENT NASAL FIBROMA

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY PRICE BROWN, M D
TORONTO

I must request your forbearance with me, for taking up your valuable time with the report of a single case We all know how little weight can be attached to individual histories, and that it is only by accumulated evidence that we can be guided to a proper estimate of the value of clinical research If this is true in reference to surgical practice, it is equally true of a wide range of subjects pertaining to our own special field Still, there are lesions in which the individual histories are so few and the few so widely spread over time as well as territory that it would seem to behoove every observer to chronicle each instance as it occurs with the hope of adding a fraction, however minute, to the information already possessed This I am inclined to think is true of nasal fibroma, and as the case I have to report presents several interesting features I trust you will bear with me while I briefly detail its history

On Nov 30, 1894, Mr A V P , aged 22 years, stenographer, consulted me about a growth located in the posterior half of the right nasal passage He was a hemophilia , had had no specific disease Family history good Parents both living and healthy No relatives, so far as he could remember, had been afflicted with malignancy or tuberculosis Five years ago he discovered a somewhat hard dark colored growth in the right nasal passage just within the choana His voice at the time was nasal and it was almost impossible to breathe through the right naris He consulted a specialist, who snared off a piece This produced profuse hemorrhage, which, however, soon ceased At different sittings during the next few weeks the snaring operation was repeated six or seven times, each time the bleeding was severe

As the tumor seemed to grow almost as rapidly as it was snared away, a microscopic examination was made and the disease was pronounced to be sarcoma On further consultation with general surgeons, it was advised that a portion of the right maxilla be removed and a silver plate inserted the case being considered one of malignant disease This, however, his people declined to consent to and he was sent to Boston and placed under the care of Drs Packard and McDonald, of the Homeopathic Hospital He remained there two months and during that time had several operations performed under ether The nature of these he could not tell, except that they were intra-nasal, attended by exhausting hemorrhages, and that the nostril after each operation was tightly plugged At the expiration of the period mentioned he was well enough to return home The doctors told him that they had removed the whole of the tumor, with the exception of a little piece at the back end of the passage, upon which they did not think it advisable to operate at the time During the following summer he had for months slight daily hemorrhages, but he spent the season in the country and they eventually ceased For the next three years he had so little nasal trouble that he did not think professional advice necessary About a year ago however, occlusion of the posterior end of the right nasal passage began to return , crusts would form which he found it difficult to void and slight hemorrhages would also sometimes occur In November the physician he consulted referred him to me

The entrance to the right nasal passage was somewhat narrow, but immediately behind it was a wide, open cavity for about one half the normal depth of the passage There seemed to be complete absence of the inferior turbinated bone , probably removed by surgical operation in Boston, as already related About an inch and a quarter from the anterior naris the passage was completely filled by a bright reddish growth springing from the septum, the vault above and the middle turbinated The attachment on the septal side extended down to the bottom of the inferior meatus The uvula was very long Posteriorly, the tumor filled the whole of the nasal cavity It extended behind the septum which it seemed to have pressed to the left On the right it was attached all the way down to the floor of the naris and lay immediately anterior to and continuous with the Eustachian tube This tube occupied a plane considerably posterior to the left Eustachian, no doubt owing to the pressure of the tumor

In other respects the health of the patient was of an ordinary character with the exception already mentioned, that he was a hemophilia He told me that the extraction of a tooth would be followed by bleeding for hours, as also would the slightest cut or scratch

The question of the best method of operating in this case was difficult to decide With so extensively sessile a growth, with base concave from side to side, snaring would be impossible, except in small fragments and by following out Ingals' method of galvano-cautery notches prior to adjusting the snare His hemorrhagic tendency also seemed to contraindicate treatment by this plan Curetting, cutting away by knife or scissors also seemed out of the question on the same ground, as well as owing to the obscurity of the situation. Post nasally, but a small portion of the growth could have been reached.

Direct surgical operation by excision of the superior maxillary and palatal bones did not seem to be required, as I did not believe these bones of themselves to be seriously involved. There was no external deformity and the only displacement in the pharynx was a pressure downward of the right side of the soft palate. Electrolysis I thought of, but having had no personal experience of its effects in deep nasal work I finally decided to endeavor to dissect it out, little by little, with the galvano cautery knife.

On December 1, I did uvulotomy to facilitate post-nasal observation. Two days later, after applying 20 per cent solution of cocain I made the first galvano cautery incision through the anterior naris into the lower part of the tumor at its union with the septum continuing the burning until the hemorrhage became quite severe. An astringent spray soon controlled the bleeding. Several days later I repeated the operation in the same way, but at the outer margin of the growth at the site of the junction of the former inferior turbinated with the maxillary bone. The hemorrhage this time was very severe and I found it necessary to plug with tailed tampons of absorbent cotton packed solidly within the nasal cavity. This stopped the flow and twenty-four hours later upon removing them there was no recurrence. After an interval of a week I made the third attempt at galvano cautery work, incising the central portion between the other two cuts. The electrode was of a bright red heat, and it had only been applied a few seconds when arterial blood began to jet out forcibly. The flow was so rapid that with difficulty I caught a glimpse of a large pulsating artery laid bare and opened by the cautery. It seemed to run across from the septum to the external wall. Having had such a satisfactory result from the previous packing, I again resorted to it. The patient lay down in my office and for a few moments the bleeding was checked. Then it began again escaping by the posterior naris and soon became alarming. Dr Reeve kindly came to my assistance and after removing the plug I packed the cavity from behind by the use of Bellocq's canula having first soaked the sponges with a combination of tannic and sulphuric acids. This effectually stopped the bleeding, but the patient was almost pulseless by the time it was accomplished, and two hours later, when being assisted to the carriage, he fainted away. This loss of blood confined him to bed for a week, and two more elapsed before he was well enough to proceed with operations again.

On looking up the literature of fibrous tumors of the air passages, I found that Kaarsberg of Copenhagen, in 1894 recommended electrolytic treatment of fibrous tumors of the naso-pharynx, giving the history of four cases, the treatment being supplemented by the use of the galvano-cautery and scissors and I decided to try it in this case of fibroma of the nose.

After applying a 20 per cent solution of cocain, as in the cautery work, I used long needles, isolated by rubber tubing, and inserted through the anterior naris into the growth at a distance of about half an inch from each other. These were attached to a 12 cell Le Clanché battery. The séances were about five minutes each, and given upon alternate days.

Notwithstanding the anesthetic effect of the cocain, the shock was very painful, even more so than that of the galvano-cautery. The effect upon the tumor was of a deadening nature, making the surface paler and producing exudation. The shrinkage, however, was scarcely perceptible. After using it through the anterior naris three times, I changed the direction of the electric current, by passing a single straight needle into the tumor from the front, and a long curved needle through the mouth and naso-pharynx and into the growth from behind. This seemed to produce a more satisfactory effect. The central portion, both anteriorly and posteriorly lost much of its vivid hue, though the shrinkage produced by four séances was almost *nil*.

Hoping by this time that the electrolysis would have the effect of limiting the severity of future hemorrhages, I again returned to the use of the galvano cautery.

From January 18 to March 15 I operated with it at sixteen different sittings, each time applying the cautery as extensively as I thought I could do with safety. Sometimes there was no hemorrhage, at others it was only slight, never severe enough to require plugging. Little by little I got the growth away. The first half of the operations were performed entirely through the anterior naris, the vision of the parts being obtained through the anterior rhinal speculum. The latter half, also, were done through the anterior naris, while the operations were guided by the posterior rhinal mirror.

To complete the work, as the pharyngeal tonsil was somewhat protuberant, I removed it with Gottstein's curettes as a precautionary measure. The bleeding from the cuts was severe, but was checked without plugging.

In the cautery work, the part I found most difficult to accomplish, and requiring the greatest care in manipulation was the destruction of the part of the fibroid attached to the anterior margin of the Eustachian tube.

The supplementary treatment consisted of daily cleansing with alkalin spray, followed immediately by removal of crusts, sloughs, etc., with the aid of cotton holders and finishing with spray of albolene.

I had sections of the tumor examined by a competent microscopist, he pronounced it a dense close grained fibroma.

With regard to the physical condition of the patient, the course of treatment was very satisfactory. With the exception of the time lost as the result of the excessive hemorrhage, he never lost a day from his professional duties. The operations were always done in the evening. Sometimes he would be restless and suffer pain during the following night, but he could always take a light breakfast and go down to his office the morning afterward. During the latter half of the treatment, notwithstanding the amount of cocain used he improved in weight, as well as in color and spirits, and I am glad to say without acquiring the slightest craving for the drug so frequently used.

One notable feature in the history of the treatment was the extent to which the palate resumed its natural functions. At first being pressed out of position it had no control over sprays thrown into the nose, and would allow them to trickle over and to drop into the larynx with paroxysmal coughing as a result. Latterly this accident would never occur, and the nose might be filled with fluid without any escaping into the lower pharynx. In fact, the control over the velum acquired by the patient aided very materially in the treatment of the case, and during this period I exhibited him to the Toronto Medical Society, so that the members could examine the tumor while still in the process of removal.

I have called this a case of recurrent nasal fibroma, believing that the original attack from which the present one must have developed was really fibroma instead of sarcoma. That the former may degenerate into the latter is, I believe, a recognized pathologic fact, but that a malignant growth could be the parent of a benign one, is certainly open to question.

What the future of the case may be it is impossible to say. At present there is no indication of any tendency to return. A new mucous membrane has re-formed. The throat is moist and the voice normally resonant. Still, that it has been completely and finally eradicated seems almost beyond hope. The case, though interesting, is too recent to base a correct conclusion upon, and I shall watch the future history with more than ordinary solicitude.

DISCUSSION

DR WARD, of Pittsburg, mentioned a case he had under treatment of a young man about 16 or 17 years of age. About seventeen months ago he suffered from the effect of a large growth in the naris and the incidental symptoms, obstruction, retained secretions, etc , were quite marked The growth protruded from the naris and extended backward into the pharynx He was in a pitiable condition when he entered the hospital Dr Ward attacked the growth with the snare and removed it *in toto* The size of the tumor was fully as great as a hen's egg Microscopic examination proved it to be a fibro sarcoma The hemorrhage during the operation was very profuse, but as soon as the growth was removed it ceased of itself A few months ago the growth began to develop again and he was sent back to the hospital What the result will be, it is impossible to say

Dr E Fletcher Ingals, of Chicago, said that he had never had any experience with fibrous tumors in the nasal cavities, but recalled a number of such growths in the naso pharynx which extended slightly forward into the nasal chambers He had removed some with the galvano cautery ecraseur On others, he had used electrolysis with good results, especially in sessile growths where there was difficulty in getting the loop of wire around their base, and he found that they disappeared under electrolysis At present he has a little fellow under observation in whom a fibroid tumor began to grow in the naso pharynx and he had removed it with the galvano cautery It subsequently returned, and in six sittings he was able to destroy almost the whole of that which appeared in the naso pharynx, but it had since extended downward to the malar bone and the nasal chambers This, he supposed, might be called a recurring fibroid of the nose It is difficult to decide how to treat these cases, but as he had obtained good results already from electrolysis, he purposed continuing it after returning home

Dr Logan of St Louis, said that his experience had been in accord with the previous speaker with regard to the prevention of hemorrhage by the use of electricity in removal of naso-fibroma He employs both the electro-cautery snare and the electro-cautery knife and found them useful both in removing the growth and in checking hemorrhage

Dr Cline, of Indianapolis referred to the case of a boy 16 years of age who had been under his observation during the past year He had a pretty large growth occluding the nose and extending into the pharynx, perhaps the size of a small orange The side of the nose was pushed out and the eye was dislocated to some extent With the galvano cautery snare he had cut off about one-third of the tumor, which on examination was pronounced a fibro sarcoma

Dr E L Vansant, of Philadelphia said that in regard to the diagnosis of these cases of tumors occurring in the naso pharynx, as Dr Brown had raised the point in the discussion, he would make the following observation He had made a number of histologic examinations in these cases and had come to the conclusion that the diagnosis depends very much on what part of the tumor the section comes from If it is taken from the outer layer of the growth, you will probably get a very fair specimen of sarcoma, because of the proximity of the mucous membrane and the proliferation of cells near the surface From a deeper layer you will probably get a very fair specimen of fibro-sarcoma or fibroma In these cases there are large venous channels which are likely to cause troublesome hemorrhage In some parts of the growth there may be spots of softening, and sections through them may give the appearance of myxema, myxo-fibroma These are due to a process of degeneration, the tumor being at first a fibroma, which undergoes sarcomatous change, subsequently myxomatous degeneration takes place, forming cysts in the growth The fact that these large vessels are formed, explains the hemorrhage, unless the galvano cautery is used He declined to say whether the paper had the proper title or not

Dr Price Brown in closing, said he was glad that his paper had brought out the history of so many cases In one respect his case differs from other cases reported , it was a sessile growth over the whole cavity of the nose, springing from the upper part of the septum the vault above and the middle turbinated body on the other side He was glad to have his experience with electrolysis confirmed both by Dr Ingals and Dr Logan, and especially in regard to its value in reducing hemorrhage He had some doubts about the correctness of the title of his paper The growth had been at first pronounced a fibroma by doctors who had seen the patient, and it was regarded as sarcoma when it was removed in Boston Three years later it came to me and I considered it fibroma It would be of interest to know if it can be properly called a fibroma if the preceding growth was a sarcoma

The Chairman—Was the growth after both operations examined by the same men?

Dr Brown—No, it was not

STATE MEDICINE vs FADS

BY GRANVILLE P CONN, A.M , M D

CONCORD N H

It is often interesting, as well as instructive, to take a retrospective glance over conditions that apparently have taken the lead in shaping popular opinion In professional work this is quite as fascinating as it is to follow the ordinary topics of the day In the present, matters that are non sensational are relegated to the background, giving place to topics that can be made to excite the imagination, and help to create a sensation Out of this has been developed the fad of being interviewed by a representative of the public press , in which, many times, the person being interviewed is shrewdly made to say what the publishers of the paper or journal believe will be graciously received by its patrons This seems to have extended to all classes of society until it has become a profession The ward politician discourses eloquently on the financial problems of the day , the would be statesman is represented to have decided views upon questions involving international law , ministers and lawyers do not hesitate to boldly proclaim to the world the necessary reforms to save the country, (yet it is rare that any two agree upon the plan of its salvation) , the physician and surgeon allow professional work of the most sacred character to be heralded through the columns of the daily press as a consequence of reporters being present at operations, or of bulletins being issued daily, describing the physical symptoms of some prominent patient In either case, by using the clinical phraseology of the surgeon or physician in charge, the language may be made so effusive as to leave the reader in doubt whether it is intended for the purposes of stock exchange, or for complimentary allusions of a mutual admiration society

These professional fads have been developed from time to time, and it has always been the province of rational medicine (which is only another name for State Medicine), to assist in showing up what is fallacious and promoting the growth of what is good State or preventive medicine is doing the same to day, and to meet these questions successfully must adhere strictly to the truth, or to what can be satisfactorily demonstrated, without recourse to what may be justly denominated imagination and theory

These conditions have been developing rapidly during the past decade Conservatism seems to have been lost in the desire to bring before the public matters that would allow a greater range of the sensational, and solid facts have been made to give place to results that have been illusionary in their character

In our professional work, preventive medicine may not seem so brilliant as surgery, nor so seductive to the general practitioner as the administration of drugs, yet the fact that a life may be saved without the intervention of either the knife or a drug, is a most gratifying result to the average human being The advanced position that surgery has taken since the close of the late war, has been almost entirely along the lines of hygiene The Army surgeon was oftentimes brought in contact with much that was suggestive, and with the broad and brilliant mental capacity which he must necessarily have in order to succeed, saw much appear that he would wish to improve The unfortunate surroundings, the unhygienic condition of the person, the immense amount of practical surgery that must be done in a short period and that under the most depressing conditions and without adequate supplies, all tended to awaken in the mind of the thoughtful physician and surgeon the idea that something was needed to complete a good work and make success the rule rather than the exception In this long struggle from 1861 to 1865, it did not take but little time to educate the surgeon to the fact that cleanliness was the foundation stone on which rested the art of surgery As a result, Listerism, Pasteurism, and various other "isms" began to assume vast proportions soon after the war closed Like a great many other things, it was considered so commonplace to be clean that it was overlooked and, therefore, when brought into prominence the pendulum swung to the other extreme and a variety of terms were used to express the hygienic conditions imposed

I well remember, about 1871 or 1872, of attending a convention of the Connecticut River Valley Medical Association, at Bellows Falls, Vt, and meeting Dr H D Holton, of Brattleboro, who had arrived home within a week from a long visit in England, where he had passed considerable time in the hospitals He came back imbued with the idea that Listerism was the all important adjunct to surgery In somewhat lengthy and interesting remarks before that Association, he went into details of the work as performed by Mr Lister, and dwelt particularly upon the fact that all the operations were performed under spray He was particularly emphatic in that especial factor as having such wonderfully good results whenever an operation was being performed, and especially in abdominal surgery

I remember very well that at the close of his remarks the late Professor Phelps of Dartmouth College who was sitting very near, and who gave him undivided attention during his whole discourse, rose up and taking him by the hand said "Brother Holton, you have got it bad, but thank God, it isn't a fatal disease Listerism is having its day, but we shall all live to see that it is simply a matter of keeping the patient clean ' Professor Phelps has passed away Dr Holton is still doing good work, and is not obliged to use the spray in order to keep his patient clean

It is unnecessary to remark that surgery has made most wonderful strides within a few years, and we naturally ask the reason for this great advance We are told that it is due to the practical use of asepsis Now the term "aseptic" does not mean near so much to me as does the good old Anglo Saxon phrase of "being clean "

The terms sepsis, antisepsis, disinfectant, disinfection and a host of other such phrases have been sprung upon the profession by the chemist and the pharmacist who have had something to sell, and consequently were always ready to assist the most conservative members of the profession by loading them down with various compounds, labeled with unpronounceable names These chemic compounds may have their use, and at certain times may have some influence in overcoming what would otherwise be septic, but to my mind true cleanliness which can be brought about with soap and water and a scrubbing brush, is necessary before we place our faith in any of these compounds

In the hygienic conditions involving a surgical operation or a surgical dressing, we should always demand true innocence instead of repentance, for repentance of the evils done in this world does not benefit the victim of a polluted water supply, contamination of food, nor of the consequence of preventable septic poison Good may come to others from such teachings, but to the friends of the victim a life is sacrificed to ignorance or stupidity, for it might have been different had there been proper care exercised

A few weeks since, under the head of "Up-to Date in Surgery," the *British Medical Journal* said in a rather sarcastic way "Modern surgery is heroic enough to please the grim prophet of hero worship It seems to have taken Danton's motto, which in English would be rendered, 'audacity, audacity, and still *again audacity* '" This calls to mind the language of that most estimable wife of our distinguished compeer, Dr John G Blake, of Boston, who, when traveling through the mountain passes and canons of Colorado and New Mexico, and asked her impressions of the scenery, replied "I don't know which to admire the most—the royal grandeur of nature, or the audacity of man as exhibited in the extraordinary feats of engineering skill ' So, with the surgical work of to-day, we are sometimes at a loss to describe our feelings as to which we admire the most, the physical beauty of God's creation, or the audacity of man in his defense of the physical body against disease

Continuing the quotation from the *British Medical Journal*, the writer says "Almost every week one hears of some surgical Alexander cutting his way to fresh conquests Is it not unnatural, therefore, that nearly every ambitious surgeon should see in the knife his '*In hoc signo vinces*' In the hands of a skillful operator the knife doubtless can work greater wonders than the fabled wand of the magician, but it should be reserved for difficulties worthy of so noble a weapon As Falstaff says of the English nation, it may be said that it was always the trick of our profession, if they have a good thing, to make it too common We can not help thinking that the knife is made a trifle too common "

Again he says "This is quite in the spirit of 'advanced surgery, which, in the words of one of its chief professors, thinks no more of opening a patient's abdomen than a man does of putting his hand into his pocket Is the day coming when a cold in the nose will be dealt with by Rouge's operation, and bronchitis treated on 'surgical principles' after preliminary opening of the windpipe?"

This is strong language, and yet to some extent it is worthy of our consideration, as at the present time there is a great predisposition for some people to become wedded to fads, and just now surgery, especially that of the cranial and abdominal cavities, seems to take the lead in the profession With the improvement and advancement made in the hygiene of such work, the opening of these cavities has become nearly or quite without any expectation of harmful results It is a matter of congratulation that every member of the profession should be allowed to have the ambition to go forward and perform all manner of operations, yet, on second thought, we must admit that only a comparatively few, in a sparsely-settled country, can become experts Continued and daily practice becomes a necessity for good work, especially where delicacy of touch and manipulation are required The same is true in regard to the hygiene of an operation, in order to prevent contamination or sepsis It appears to me sometimes, that we are prone to give our attention almost entirely to the opening of cavities, especially so far as the prevention of sepsis Our books and our journals are full of instructions, especially in the opening of the cranial and abdominal cavities, and while they give you some general instructions regarding the minor operations, yet they are comparatively silent on such matters as are of daily occurrence to the profession at large

It is only recently that I have observed in text-books or in journals any allusion whatever to the preparation of a patient for so simple an operation as vaccination as it is generally understood that everybody must know how to vaccinate In fact, it has become so common that the laity themselves think they can do it just as well as physicians, and all of us have had experience with that class of people I believe the time is coming when by the use of preventive measures the operation for vaccination will be made one of importance, in which the arm, clothing and the surroundings will be made as nearly perfectly clean as it is possible I have remarked to medical men and others that if we would approach a child who was to be vaccinated, and prepare the arm and the clothing and all the surroundings with the same care that we would if we were going to open the abdominal cavity, we should have far less trouble, there would be far less complaint of sore arms, and the possibility of other troubles, aside from the vaccine virus taking hold of the system of the patient It is not my purpose to speak particularly of medicine or those auxiliaries of surgery beyond that of preventive means relative to surgical operations I have great respect for the pharmacist who has been of value to the profession in bringing certain things to our notice, but I object to his assuming that we can not get along without him The truth is, this work of advancement began and was made possible by our professional knowledge of hygiene For some years before 1861 there had been but little advancement in surgery, which at that period was almost entirely confined to the extremities Suppuration was the rule, and although the text books taught that we might get union by first intention, yet they signally failed to teach us how it could be achieved A good story is told of a surgeon and house officer of the period of 1870, and the same again in 1894, which runs as follows

In the year of our Lord, A D 1870 Scene surgical ward

SURGEON How is Jones doing?

HOUSE SURGEON Extremely well, sir, the wound is suppurating nicely

SURGEON That's all right

Time In the year of our Lord, A D 1894 Scene same surgical ward

SURGEON How is that amputation of the breast?

HOUSE SURGEON I'm sorry to say, sir, the wound is suppurating

SURGEON What! Suppurating! Do you say suppurating? Well I'll be ———

It is true that McDowell and some others had opened the abdominal cavity, but in doing this wonderful operation they had brought down upon their heads the scorn and the abuse of the majority of the profession, for they had utterly failed to give any reason why such operations could be safely performed While hygiene was known to be as old as the world itself, its simplicity was so universal that it had fallen from its high estate and had become one of the lost arts It is to be remembered that in Holy Writ, we find in the law of Moses, much that pertains to hygiene and sanitation, and I sometimes wonder if it is because we find those matters in the Bible that so few seem to know that they ever existed But whenever we look this matter over and come down to the vital principle, we are always confronted with the same thing, viz, that cleanliness is the foundation of all good surgical work No matter how much we may have of carbolic acid and various other drugs and chemicals which are put upon the market and advertised largely, without cleanliness, without soap and water and the scrubbing brush, we shall utterly fail of doing good work These are the hygienic measures on which surgery depends, and without which surgery would soon fall back to the low estate which it had prior to 1860 The most of the compounds which are placed upon the market are empirical in their character, and cost out of all proportion to the good work which they may be expected to perform I am always suspicious of any man or physician who indulges in rhapsodies over some new medicine or compound We should look out for him He will bear watching carefully, for he may be but an advance agent, and is talking for the money in it, the same as the advance agent of a circus, or any other advertising agent Many drugs and surgical supplies are advertised in our medical journals in which we have no confidence, and while there may be members in the profession who use them, yet it is generally expected that the public will purchase, rather than the profession The advertising which some of these compounds get is simply ridiculous, and should not be tolerated by any member of the profession, or even any person of common sense

The following item regarding a wonderful medicine is taken from the *New Idea*, and is presented you as an illustration of an extravagance in language that none but a mountebank or charlatan would assume, and yet it is only in a line with the exalted conditions the commercial traveler, representing manufacturing firms, would have us believe, and should we venture to express doubts regarding the infallibility of their compounds being as efficacious as their expression of confidence would lead one to expect, they seemed pained at our ignorance, and sometimes actually intimate or insinuate that you are but a back number The item was as follows

"Chetterback's Balsam of Balsams Nature's Palladium Should you chance to have your brains knocked out, or your head chopped off, two drops of this seasonably applied will recall the fleeting spirit, reenthrone the deposed arch, cement the discontinuity of the parts, and in six minutes' time restore the lifeless trunk to all its pristine functions, vital, rational and animal"

To which the editor comments as follows

"A full bottle of this will also make a sausage wag its tail and bark, and a jar of extract of beef, bellow or give milk"

Barnum once made the remark that the public loved to be humbugged and the suggestion has been acted upon by the maker and vender of patent medicine for many years

Fortunes have been made, human beings have been drugged, and the constitution of future generations has been impaired, until the philanthropist and the reformer should at least class this evil with that of intemperance

It is not strange that the manufacturer of pharmaceutic preparations and surgical supplies, in the sharp competition of business, should fall into the same line, and shrewdly making use of the profession to bring out his products, be able to build up large business plants, and from his profits rival the dealer in patent medicines, in the elegance of his mansions The physician and surgeon should always think for himself The profession should direct public opinion on all matters of professional interest, instead of having it brought round in the grip of a commercial traveler The surgeon should never confidingly allow the use of some compound when he is not thoroughly informed of its chemic constituents We know that absolute cleanliness, with abundance of air made absolutely aseptic by the great cleansing power of heat will prevent infection from without, and give our patient every chance from the possibility of auto infection from within

One other matter I would like to bring to your notice It is true it has not thus far been intruded upon the surgeon to the extent that it has been upon the physician, but I anticipate that ere long some bold disciple of the commercial travelers union will come round to our office with a gripsack full of samples, for the relief and cure of such a variety of surgical diseases "that,' using his own language, "no reputable surgeon would ever be without a large stock ready for immediate use ' The following from the pen of one of our profession, ever ready to meet imposition in every form with ridicule and pungent wit, will serve to invite serious thought and investigation into a class of remedies that is being heralded to the world with all the brazen effrontery of empiricism I give it to you as only a partial list of extracts

> ' An extract of muscle for rheumatic pains,
> A gray-matter extract to nourish our brains,
> An extract of teeth for a man that can't chaw,
> A maxillary extract to cure lock jaw,
> An extract of ocean to cure mal-de mer,
> A hirsute extract for those without hair,
> A duodenal extract to serve a good turn,
> In healing the ulcers that follow a burn,
> An extract made out of a whole population,
> To rescue some housewife from sterilization "

Medical journals wielding considerable influence in the profession, unblushingly open their advertising pages and with sensational head lines intimate that any one who reads can be raised from the depths of despondency, if they will only send for these specifics To the reflecting mind it seems as if any educated person would at once distrust such dogmatic assertions, yet in the present, it is becoming a fad to follow the bacteriologist and the biologist through the devious pathways of the laboratory, and accept the diagnosis of the culture tube without question

True scientific investigation and its deductions should be the admiration of every member of the profession, but do not be in such hot haste to accept conclusions as to overthrow and trample upon such common sense opinions as have been set forth by State Medicine, as well as the axioms and aphorisms of the science and art of medicine and surgery that have been in the past and must be in the future, beacon lights to guide professional opinion, thereby avoiding the dangerous shoals of dogmatic assertion and empirical insinuation

The bacteriologist and biologist are doing good work, but many of those performing the most labor in this department are not practical physicians and surgeons, and therefore do not test the results of their own study Should such students become enthusiastic and fascinated over the secret processes revealed through the culture tube and the microscope, will it be always safe to follow in their lead without something more than theoretical assurance? I have great respect for newspapers and medical journals, as well as for the enterprising men who serve as the medium of communication between the people of different sections of the world, yet they oftentimes defeat a good object by prematurely bringing before the public the work of the scientist Less haste and more conservatism would develop less fads, but more real science The sensational might be far less prominent, but real worth would be a solace to the profession

A summary of this paper may be concisely stated in a few words

Always investigate for yourself Do not allow " isms' nor fads to become a part of your daily prescriptions Hold fast to that which is good, and promptly discard all that will not bear a searching scientific investigation, under a light as strong as the noonday sun

And lastly with a thorough knowledge of hygiene, therefor fully realizing the powerful influence of State Medicine in counteracting the deleterious effects of fads and theories that are but a figment of the imagination (fostered by minds already dazed by an all-absorbing desire for pecuniary gain), we should not forget that in surgery we have in absolute cleanliness the true foundation of practical success

---

THE NATURE OF A DELUSION

BY J SANDERSON CHRISTISON, M D

CHICAGO

My article entitled, " The Essential of Insanity," which appeared in the JOURNAL of October 19 contained an argument supporting the proposition that " where there is no delusion there is no insanity, for the mind that is competent to comprehend facts and their bearings within the scope of its education and the limits of ordinary surroundings is a mind capable of correction on any error, and conversely, a mind that is not thus competent must of necessity beget delusion of one form or another which it is as incompetent to discharge, no matter what the evidence combating "

Since the presentation of that article for publication (last spring) I find in the present autumn number of *Brain*, p 328, the following words of Prof C Mercier, of London, in his discussion of a paper by Dr Batty Tuke Dr Mercier expresses his gratification at Dr Tuke's complete acceptance of the doctrine, which, says he "I have long held and preached but which has never before, as far as I know, had any adherent, that insanity and disorder of mind are not convertible terms and that disorder of mind—grave and prominent disorder of mind may exist in a sane person and without the question of insanity being even raised "

When two such authorities so enunciate, I think I am very nearly cleared of heresy in my proposition and believe the day is dawning when doctors on the stand will be less confused and confusing on the subject of insanity

In the same article, I also asserted that a delusion had three components or elements of aberration, viz, 1, error of fact, 2, error of inference, and 3, illogical tenacity

1 The basis data or premises of a delusion are not all true and they are not necessarily all false, but must contain some error or illusional feature or hallucination in any case This is evident from the law of association which requires at least one quality or idea for a leader to bring others into a particular relationship, fitting or false, otherwise an inference or delusion could have no attachment and therefore no existence The error may be supplied by the senses or the imagination or may exist subconsciously, as when the delusion takes the form of a feeling or emotion or impulse

If the law of the association of ideas were inoperative chaos would result, and if only partially operative as in the delusional state, the same result would take place, viz, error of fact, as we would have jumbled facts—or facts in malposition giving erroneous perceptions A part truth is an untruth But the law of association more or less prevails except in recollection which is a voluntary act and is necessarily affected owing to reduction of will power Memory, which is technically the term for the conservative faculty, but is also used to mean the involuntary return of ideas to consciousness through natural or habitual association (as in the lower animals), continues comparatively unaffected as it is operative in all passive states of mind, not preoccupied

Again, as the mind is a unit (its faculties being but interdependent modes of activity) and as it is the same faulty mind which perceives the basis data that conceives their relationship, it is evident that to suppose it correct in the one case and not in the other is to assume that an insane mind can be sound and unsound almost simultaneously

Everyday things and things that are common, habits that are automatic or almost so from repetition, and arguments or reasonings that have become habitual or familiar, are less likely to be affected than those requiring consideration or of recent acquisition and thus much of an insane person's behavior and talk may be quite normal or even smart Accordingly much of the basis data of a delusion may be true with one or more of the less familiar facts distorted through imperfect attention, or an entirely false one may be obtruded by hallucination

2 That a delusion also contains an error of inference—an illogical deduction from the data as they appear to the subject, is evident from the last reason given for error of data If the mind is accurate in perception there can be no basis for a delusion and therefore no delusion, and conversely, if it is accurate in inference, it is capable of being accurate in perception and the delusion would dissolve as is the case in restoration from insanities

3 By illogical tenacity I mean the irrational persistence of the delusion in the face of positive and contradictory evidence sufficient to refute, so that the delusion is maintained, not because of ignorance—which is chiefly the case in common or simple delusions—but because of volitional inability to direct the mental operations beyond the ideas as they appear to the subject In other words, the attentive power of the mind has become subjective to elementary details rather than the associating principles and, as a consequence, the last conception is retained simply from the lack of the cerebral energy requisite for a progressive mentation which would give the correction A patient may argue rationally along lines of previously established habit on common knowledge even with reference to a delusion, the birth of which may only be accounted for in the same way that we account for an intuition—a subconscious action of previously acquired ideas true or false

CONFUSION, EMOTION, IMPULSE, FEELING

Psychologically, I do not distinguish any essential difference between what are called insanity of conduct (a form of hysteria), insanity of feeling (impulse), moral insanity and such a distinctive form as homicidal mania The subjects all, to a certain extent, know what they do at the moment of committing a crime But when not shamming they are impelled to their acts by the domination of a delusion which they can not overcome Whatever is not purely automatic is more or less a conscious act (even including somnambulism and hypnotism to a limited extent with forgetfulness following) and as such, must be the product of an idea, right or wrong, distinct or confused If all intellection ceases, what is to direct or move the hand and foot? The will can not act without an idea, no matter how perverted the mind may be The nervous individual who ascends to a giddy height and experiences an impulse to jump from it, should he jump is impelled by the delusion that he must do so, which is insanity, as the facts facing him confute the necessity for the act

That a correct minded person should become possessed (as many allege) with such a feeling, notion or impulse, whichever you choose to call it, and be actuated by it, is simply inconceivable In cases of such extraordinary morbid feeling there must be an existing cerebral perversion—a delusional basis which breaks from its last thread of reason by the strain of the situation which may focus the ideational confusion into a delusional impulse, but which may have had a previous conscious existence I have never heard of any one jumping under such circumstances except suicides But we occasionally meet with persons who have experienced such alarming neurasthenic feelings but managed to control them as the normal will still ruled

Confusion, feeling, emotion and impulse are simply degrees of ideational activity without a corresponding degree of self control, and thus the delusion existing may be indistinct

The moral crook (kleptomaniac, pyromaniac, etc) who keenly appreciates his unenviable predicaments, is another neurotic who may have a dominating delusion, although in some cases acquired as a habit and only at times or periodically in action Like the hysteric or epileptic, his conduct has a motive idea or cause that is often obscure and perhaps immediately forgotten after the act, but none the less insanely delusional for the time being

A Sure Testimonial.—From the New York *World* Patent Medicine Agent "Madam, did your husband use the bottle of Professor De Fakir's Animal Extract I left him"

Wife 'Yes It took immediate effect "

Agent 'Good' Then you can conscientiously say that he will use no other?'

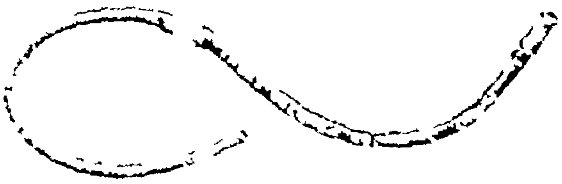
Widow "I'm quite sure I can He is dead'

NEW INSTRUMENTS

AN AURAL MASSEUR

BY FRANK ALLPORT M D
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE MINNESOTA STATE [illegible] EX-PRESIDENT [illegible] NESOTA STATE MEDICAL SOCIETY ETC
MINNEAPOLIS MINN

The question of the benefits derivable from aural massage in middle ear affections is still unsettled, but many advocate its employment Improvement doubtless occurs in some cases under its influence, and the necessity for a good, efficient, cheap and handy instrument is apparent These merits can all be obtained in the appliance here described, the principle of which was suggested to me by my friend Dr W N Porteous of this city



The instrument consists of a piece of thick rubber tubing, one yard in length, of dark color, to prevent soiling The tubing is severed in the middle, and some glass tubing inserted to connect the two ends In this glass tubing is loosely placed some cotton The object in thus inserting the glass tube and cotton is to insure cleanliness to both surgeon and patient, as it prevents anything passing from the patient's ear to the surgeon's mouth, or *vice versa* As the cotton is *apt to pass out of the glass tube* during the massage treatment it would be better for the surgeon to fasten it in the tube by a drop of mucilage On one extremity of the tube is impressed the word "Mouth," showing that this end is for the surgeon's mouth This extremity is also fitted with a hard rubber mouth-piece The other end is impressed with the word "Ear," showing it is for the patient's ear The rubber is here left free and soft, as it can thus be best fitted into the meatus and its insertion is unaccompanied by pain

When it is desired to use the instrument, one end is securely placed in the patient's meatus and held there by the surgeon The other end is put in the surgeon's mouth and suction applied as weak or strong as is desired By sucking in and out, as it were, a vibratory movement of the drum-head and ossicles may be obtained, which can be continued as long as is thought proper—but a minute or so will probably be sufficient

Care must be taken not to proceed with this application too vigorously, as great force may be obtained and unfortunate results produced, such as a rupture of the drum-head, blood blisters in the meatus, etc

SELECTIONS

Report of 1,000 Goitre Operations—(Kocher, at the twenty-fourth Congress of the German Society for Surgery, April, 1895) When Kocher presented to the Congress the report of his first 100 operations twelve years ago, he pictured clearly the strumous cachexia In the last 900, never has the strumous cachexia been presented, except in one case After deducting the malignant cases, which demanded complicated operations, out of 870 cases only 11 died, and this number includes such cases as were *in extremis* on admission to the hospital Five deaths were not directly chargeable to the operation, three were cases of Basedow's disease, the latter showing the justice of Mikulicz's decision that the operation is more dangerous in Basedow's disease than in simple struma Therefore in such cases Kocher disregards complete excision and is satisfied with a ligature, and ties only three arteries In one case in which four arteries were tied, tetany set in immediately Of the simple, uncomplicated cases only three died In the last 900, there was no death from chloroform, in the first 100, one One case of bronchitis from ether with fatal outcome is noted In general the anesthesia was started with chloroform and continued with small doses of ether With severe dyspnea it is better to operate under cocain, which is well borne Only two deaths were due to infection, and both were secondary operations There was one series of 272 operations without a death Although these favorable results fill us with pride, yet the patients would be more thankful and it would be a triumph of science, if the prevention and cure of goitre could become merely a question of rational nourishment The researches of Kocher's assistants, Lang and v Trachevsky, have now shown that long-continued thyroid feeding will diminish the size of a goitre and even bring on a condition of atrophy, so that the danger lies in abolishing the function of the thyroid Though these experiments were carried out on animals, yet they are important Kocher has, in connection with v Trachevsky, extirpated the thyroid in pregnant animals with the view of ascertaining whether fetal cretinism can be produced And in fact rachitic young have been born Further, v Trachevsky has demonstrated that atrophy of the thyroid can be induced by administration of phosphates And already Kocher has shown that a rapid improvement in Basedow's disease follows treatment with sodium phosphate v Trachevsky draws the conclusion from this that the condition of the thyroid stands in close relation to the amount of phosphate in the human body And the assumption is not far removed that the growth of a goitre can be influenced definitely by suitable feeding In proof of this Kocher has shown two photographs of a man (before and after treatment with thyroid juice) in whom a colossal struma completely disappeared in one and one half years under purely dietetic treatment—*Centralblatt für Chirurgie* July 6 1895

Thyroid Feeding for Syphilis—From the military hospital at Warsaw comes the account of the internal use of fresh thyroid gland from an ox in a severe case of secondary syphilis which had not improved under mercury and iodid of potash The thyroid was cut into small pieces reduced to a pulp and fed to the patient with bread butter and salt Improvement began on the third day The deep ulceration of the nose and ear soon healed Temperature fell, appetite improved, and weight increased There had been great emaciation The patient complained at first of nausea, palpitation, and trembling of extremities, and the pulse rose to 120, but these symptoms disappeared The dose at first was 2 grams, with a daily increase of 2 gm until 14 was given, and the treatment was omitted every third day—*Wiener klinische Rundschau*, Sept 15, 1895

Autoscopy of Larynx and Trachea (examination without mirror)—Kirstein applies this title to a method of direct inspection of larynx and trachea by the eye alone, and he insists that it is possible in many cases even as far as the bifurcation After application of cocain to pharynx and epiglottis, the patient is placed in the horizontal position with head hanging over the edge of the table The autoscope is a short, thick semi-cylindrical instrument, joined at a right angle with a Casper's electroscope This is introduced into the mouth, moved along the posterior wall of pharynx to the level of cartilages of Santorini, then pushed forward by a quick upward movement, by which the tongue is pressed forward and the epiglottis raised Now under favorable electric lighting the larynx and trachea can be directly inspected, and the autoscopic picture is far superior to that with mirror—*Wiener klinische Rundschau*, July 21, 1895

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman Venetian Building Chicago, Ill , sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago

SATURDAY, NOVEMBER 16, 1895

THE PASSING OF HYPNOTISM

Hypnotism as a therapeutic agent is now having its day in regular medicine, but it is a day that is probably well past its meridian The belief that it has its dangers and that these overbalance its possible benefits has grown within the past few years, and the number of regular physicians who use it in their practice is probably very markedly on the decrease It is legitimate to utilize pathologic conditions and even to produce them in therapeutics, but it must be demonstrated as of utility on reasonable *a priori* grounds, or, at least, have the best of clinical and experimental evidence in its favor to make it expedient or justifiable When, with a better knowledge or theory of the condition the *a priori* deductions tend to its disfavor as a healing agency, only the most decided clinical proofs of its value, applying not only to immediate but also to remote results, should be required before its use in the treatment of disease is countenanced to any extent

The revival within the past sixteen years of interest in hypnotism, the claims of the Nancy school and the published accounts of the experiences and practice of numerous physicians and scientific men of repute such as FOREL, VOISIN, BENSWANGER, BRAMWELL, and others, have given it a certain status in legitimate therapeutics, considerably beyond what it possessed in its former period of cultivation some fifty years ago

It is probably not known to the general medical public of to-day, or if known is forgotten, that at that time it had its popular pseudo scientific standing and was investigated by men of science, who came to very much the same conclusions as those of the present day This fact has been well shown by DR J G KIERNAN in a paper published in the *American Journal of Insanity* at the beginning of the present year, he shows that the earlier alienists of this country *recognized the dangers of hypnotism*, its psychologic basis, and the element of morbidity that is required to predispose to susceptibility The outcome of the whole at that time was to relegate it back among the pathologic curiosities of little practical value, and it slumbered, in a medical point of view for over thirty years

It seems probable that we are to see history repeat itself, and that before many years the medical profession will drop hypnotism as a therapeutic agent, at least, that will be the general if not the universal rule, and that its use will be mostly confined, as it was during the years between 1848 and 1880, to the irregulars outside of the recognized schools of medicine That is its tendency at the present time, and while some unquestionably able men are still experimenting with it, a too great credulity as to its value and powers has seriously injured some high scientific reputations, that of LUYS of Paris, for example, among others We need not particularize here on what may be rightly called the thoroughly disreputable therapeutics of hypnotism, as applied by certain prominent German physicians—they have before been editorially alluded to in the JOURNAL

The dangers of hypnotism are already indicated when we consider its close relationship to hysteria and to hysterical conditions which has been shown by CHARCOT, GILLES DE LA TOURETTE and others in France, Germany, and elsewhere Of all pathologic conditions hysteria would seem to be one of the least likely to be therapeutically useful, and the utilizing of hysteroid anesthesias and other disturbances of consciousness, going so far, even, as to the production of what may perhaps be properly called epileptoid conditions of double consciousness and amnesia, without regard to the after effects of such disordered cortical functioning, is not a procedure that ought, it would seem, to be countenanced as a legitimate method of treatment of any condition, a condition, moreover, in which the will is in abeyance is not a normal one and its tendency must be to weaken the inhibitory power of the brain and change its functions, possibly even to the extent, in some cases, of producing serious mental disorder As HACK TUKE mentioned, some thirty years ago, hypnotic conditions have in a fashion something of the character of an induced temporary insanity, and their too frequent repetition may make the derangement a permanent one Such has undoubtedly been the case in not a few instances, to say nothing of the aggravations of hysteria and even the production of epilepsy in some cases The dangers of hypnotism are real, and the fact that the majority of the victims escape the worst of them, does not in any way excuse the reckless ex-

The discovery of the aerobic modification of *Bacillus tetani* in mixed cultures is not original with CARBONE and PERRERO, since the fact has been noted by other bacteriologists, as BELFANTI, SANCHEZ TOLEDO, and VEILLON, and the same variation has been observed with the bacillus of malignant edema by PENZO. More recently still, this very interesting symbiotic relationship of the aerobic and obligate anaerobic bacteria has been experimentally studied by KEDROWSKI (*Ueber die Bedingungen, unter welchen die anaeroben Bacterien auch bei Gegenwart von Sauerstoff existiren können, Zeitschrift für Hygiene*, Bd XX, Heft 3, 1895), who has shown that the tetanus bacillus and an anaerobic species obtained from butyric fermentations grow readily in the atmospheric air when associated with a number of species, both of strict aerobes and of facultative anaerobes.

ADENOMAS OF THE LIVER.

Among the new growths occurring in the liver, the adenomas should have a peculiar interest for the pathologist and clinician, both on account of their relative frequency in this viscus, as well as their interesting structure. This latter has given rise to considerable discussion, and at present the consensus of opinion seems to be that these tumors are so intimately allied with the carcinomas on one hand, and the cystomas on the other, that no sharp line of distinction can be drawn.

Like most questions connected with pathology and pathologic histology, it is only in the present century that adenomas have been recognized as a distinct pathologic entity. The recognition of the finer details is a question of the last few decades. First noticed in the mammary gland, they have been successively described from other glandular structures, until they are known to occur in the breast, kidneys, liver, salivary, sweat and lacrymal glands, the glands of the stomach and intestine, etc.

In 1829 the famous surgeon SIR ASTLEY COOPER, described a "chronic mammary tumor" occurring principally in females from 17 to 30 years of age, and differentiated it from regular hypertrophy of the breast. Ten years later VELPEAU mentioned the occurrence of "fibrinous tumors" which he thought were caused "by the organization of a greater or less quantity of blood or other matter extravasated into the breast, following a blow, contusion, etc." In 1850 LEBERT[1] described four tumors of the breast markedly differing externally but agreeing in presenting glandular cavities internally, lined with epithelium. He considered them to be the same as the chronic tumor of COOPER and the fibrinous variety of VELPEAU. From this time on, our knowledge of the growths was rapidly extended by various investigators.

If we were inspecting a liver containing adenomata, we should find the organ enlarged as a rule, the surface generally nodulated, though sometimes the growths are hard to find, and the organ must be nearly "hashed," as one author expresses it, to discover them. The tumors are of various sizes, from a grain of wheat up to a small orange. They are multiple, and as a general rule the smaller they are, the more numerous. The color is sometimes grayish yellow, if infiltrated with blood reddish, but mostly of a decided golden yellow, contrasting strongly with the rest of the organ.

Microscopic examination shows the growths to be made up of little *culs de-sac* of epithelial cells turned in various directions and bearing a more or less close resemblance to a gland, seeming as if some one had started to make a gland and then abandoned the effort, leaving the material strewn about. As a rule, two general patterns may be noticed—the tubular and the alveolar. These epithelial deposits are surrounded and supported by a stroma of connective tissue which may be thick and abundant or thin and sparse.

As already stated, our adenomas are closely related to carcinoma, hence there is the usual diversity of opinion as to their true nature. MM KELSH and KIENER[2] claim an adenoma is merely a form of special irritative hepatitis, a special epithelial cirrhosis. SABOURIN[3] sees in adenomata a true epithelioma, but of specific nature, a reaction of the liver cell from the influence of some unknown cause of irritation. QUINQUAUD[4] looks upon these growths as nothing but cylindrical epitheliomas. BRISSAUD[5] claims an adenoma is an epithelial tumor which may be transformed into a cancer at any moment. Finally, MM. HANOT and GILBERT[6] in their classic treatise look upon adenoma as only a name given by the earlier writers to a variety of primitive cancer of the liver.

This diversity of opinion is found also when the origin of the connective tissue stroma is explained. SABOURIN remarks: "While the walls of the capillaries are not modified by cirrhosis, the adenomatous cylinders are destitute of proper walls like the hepatic trabeculæ which they replace." Thus adenoma seems to be only a complication or an accident in the cirrhosis. According to LANCEREAUX[7] the cirrhosis is secondary and is a result of the neoplasms developing in the liver. KELSH and KIENER as well as HANOT and GILBERT think the cirrhosis and the adenomas develop simultaneously under the influence of the same irritating agent.

The pathogeny is still obscure. As regards age they are an appanage of early life, those of the rectum are especially frequent in children. BROCA[8] gives a table of ninety cases in various glands, in forty-two, the ages were less than 30, in twenty eight, from 31 to 40, and in only twenty was the age over 40 As LANCEREAUX remarks [9] "This shows the genesis of these tumors to be related to the period of formation or development of glands"

[8] Traité des Tumeurs I, p 446

The symptomatology recalls both that of cirrhosis and that of cancer The onset is often made and ushered in by divers digestive troubles, disgust for food and especially meat Dull pains occupying all the abdomen, especially the right hypochondrium and increased by profuse meteorism, ascites and wasting follows rapidly The volume of the liver varies, if cirrhosis predominates it is small and retracted behind the ribs, most often it is increased in size, the surface hard and nodular, the subcutaneous veins of the abdomen are dilated [10]

The spleen is of but little importance from a diagnostic standpoint, for according to HANOT and GILBERT, it is as often small as hypertrophied Icterus is present nearly constantly, while vomiting, intense from the onset as a general thing begins slowly and progresses steadily until the end Contrary to what we see in other forms of cirrhosis, hematemesis, melena and albuminuria are exceptional LANCEREAUX has observed an anemic cardiac murmur in some cases

As regards duration of the disease, after it has existed a few weeks or months the phenomena are aggravated, vomiting is frequent, dyspnea is continuous and the patient dies comatose or after syncopic attacks In most cases this fatal termination occurs in two to four months, and the extreme limits assigned by HANOT and GILBERT are five weeks and sixteen months

Unhappily, as THERESE[11] remarks, "when the diagnosis is established there is but one prognosis, and treatment so far has been palliative only"

CORRESPONDENCE

Medical Examiners' Fees

CHICAGO ILL Nov 12, 1895

To the Editor —I perused with much gratification the instructive paper entitled, 'Practical Life Insurance Examinations," by Dr John L Davis (JOURNAL, September 28), and more recently enjoyed the discussion upon this topic by Dr W W Vinnedge, of Lafayette, Ind, (JOURNAL October 12 and 26) and lastly, the views set forth in your editorial on this subject

One of the most important questions perhaps that arises in my mind is this, What are Dr Vinnedge, and all his confrères throughout the country going to do about it? Suppose the life insurance companies named (and others are likely to adopt the same course) have reduced the fee for medical examinations, shall they—these companies who have accumulated and own millions of dollars worth of assets and in hundreds and thousands of instances have relieved the distressed and unfortunate, be boycotted? Shall abler and more experienced physicians stand aside to make room for the younger members of our profession, that they may receive appointments as local medical examiners, medical directors, *et al?* Or shall we accept what is offered us by these wealthy life insurance companies—the reduced fee of $3, and be content?

The editorial in the JOURNAL of October 26 certainly has voiced the sentiment of the great majority of the profession, especially the members of the AMERICAN MEDICAL ASSOCIATION, on this important subject, and, so far as it goes, without having entered into minute details is sound But there is something else to be considered beside money making, in a careful physical examination of an applicant for life insurance, which I shall refer to before closing this letter

Regarding the reduced fee, as I understand it, this reduction was substantially agreed upon, at the meeting of medical directors of various life insurance companies held last May in New York after adjournment of the Baltimore meeting It was decided then to reduce the fees of the local medical examiners of some of the oldest and best known companies in the United States At the aforesaid meeting however, nothing was said as to these rich and powerful corporations reducing the amount of premiums for the policies they sell, nothing was said about pruning salaries or devising ways and means to reduce salaries of higher-priced officers, neither was there anything stated or done as to the said companies reducing their rate of interest when they loan money upon desirable "gilt edged" security Nor was there any discussion upon the matter of lessening rents to tenants of buildings owned by these magnificent corporations, for it was not the business of these gentlemen to discuss any of those material topics, nor is it known that retrenchment and economy in other departments were considered or advocated Solely the reduction of fees of their medical examiners was decided upon, etc

Apropos to this question perhaps your correspondent, Dr Vinnedge, and a few thousand other able practitioners have felt this indignity Physicians who for years perhaps, or during their time of appointment as medical examiners have extolled the advantages of 'their" life insurance company over *all* competitors, for which they received no emolument, are now obliged to accept reduced pay or resign In all sincerity, may I ask, is this fair *treatment on the part of* these immensely rich corporations?

But suppose the reduction does not stop at $3? I understand from the most reliable source that a certain life insurance company which is rated to be one of the largest and strongest companies financially doing business in our country, has gone farther and proposes hereafter to pay something like 83⅓ cents to their medical examiners for each examination made In Chicago the company mentioned has agreed to pay each of its medical examiners a salary of $1,000 per annum—and the company guarantees to give to each of its examiners 1,200 examinations during the year Or, rather the examiner is obligated by contract to do this amount of work if needs be for his company If the foregoing statement can be disproved, I should like to have some one knowing it to be otherwise, prove the contrary

Several life insurance companies doing business in Chicago have appointed as their medical director or chief medical referee, a specialist Again I may be pardoned for venturing to inquire, Is this fair and honest to the men who do general practice, particularly when our "specialist" friends —most of them, at least, announce and invite our attention to the fact that their practice is limited to the treatment of a special line of disease? Therefore to my mind, it does not seem quite consistent for an oculist, aurist, gynecologist dermatologist alienist, neurologist or an expert in mental or nervous diseases, or one whose practice is limited to diseases of the nose and throat or other special branches in medicine, to accept a position as medical director, medical referee or medical examiner of a life insurance company On the other hand, it might appear also that the sagacity of a company would induce it to select some other than a specialist for its chief medical adviser

---

[9] Traité d Anat. Path I p 410

[10] Thérèse Union Méd 1895 No 34

[11] Loc cit

As to agents for life insurance companies, to whom reference has been made, these are varied in quality and kind My experience and acquaintance with them, is that as a rule they are a pleasant, agreeable and courteous class of gentlemen and sociable to the highest degree—gentlemen who command the respect of the community in which they reside

I take it for granted that all companies as a rule, try to secure medical gentlemen of professional skill and ability, men of sound judgment, and who are thoroughly versed in technique and are "broad gauge" in the theory and general practice of medicine

I would say in conclusion in replying to the first proposition of Dr Davis "that physicians do not give '*quid pro quo*' for the professional service they render life insurance companies" in my opinion a conscientious physician always endeavors to give 'value received' for his services, as he certainly should be a careful and skilled diagnostician It is probable, too in numerous instances that the examiner may have to call twice or even thrice upon the applicant at his residence or place of business, only to find him absent or otherwise engaged Then he has to return to his office to complete the report of his examination all of which requires valuable time and patience In such instances the examiner has well earned a $5 fee and frequently the general average of cases are not unlike the above hypothetical one

Very respectfully yours,

Liston H Montgomery, M D

70 State Street

The Protonuclein

Goshen, Ind, Nov 8 1895

To the Editor —I saw Dr Summer's able and interesting paper, printed in the Journal last June, on the subject of the nucleins And being interested in the study I concluded to make the inclosed imperfect notes of a case treated with the protonuclein

Oct 1 1895 I was called to see a child aged 2 years, son of Mr W living in the country The child had been sick one week under the care of other physicians On examination, I found the following symptoms of cerebro spinal meningitis, viz high fever irregular pulse, uneasy, with apparent pain, muscles of neck rigid, head drawn back could not be raised without lifting the body, eyes staring, complete paralysis of both legs Knowing full well the failures of all the old time treatments in so grave a case I determined on a new departure I ordered 2 grains of the powdered protonuclein to be given every three hours This course was continued for one week night and day The medicine was given at longer intervals for two weeks longer No other medicine was given during this time, except a small dose of calomel on the second day

The protonuclein had not been taken one day before the child began to show marked improvement in every bad symptom—except the paralysis It began to move the right leg five days after the beginning of treatment—the left leg a few days later It was brought to my office ten days ago, apparently in perfect health I consider this case and recovery more noteworthy, from the fact there were other cases of cerebro spinal meningitis in various parts of the county about the same time—all fatal so far as I have learned Not far distant, there were two or three fatal cases in one family

About six months ago, I was fortunate in getting a supply of protonuclein At first I was slow to rely upon it alone, to the exclusion of other medicines but my confidence has increased with my experience, and I now prescribe it in all proper cases, with the full assurance that I lose no valuable time in doing so I could report many cases of tonsillitis, diphtheria and la grippe in which the protonuclein treatment, both as curative and prophylactic, has acted like a charm

Respectfully, A C Jackson, M D

The Ohio Cases not Leprosy

New York, Nov 7, 1895

To the Editor —You published in the Journal, November 2, an article in which Dr McDougal asks, after describing two cases, "is this leprosy?" In my opinion they are not lepers I inclose you a letter I wrote to Dr McDougal

Dear Dr McDougal —Thanks for your information about the supposed leper cases, and for your article which you were kind enough to send me I have written my opinion to Dr Morrow, who had sent me the photograph of the cases I do not consider them lepers Colles law, I think, proves them to be syphilitic Certainly if they were lepers, the mother would have been infected too

Yours truly,

Albert S Ashmead, M D

Cases of Optic Nerve Atrophy of Obscure Origin

Atlanta, Ga, Nov 2, 1895

To the Editor —In two issues of the Journal, Dr Würdemann gave an account of the Ophthalmic Section at the last meeting of the American Medical Association In that account in giving the (above) committees as appointed, he gave my address as 56½ Whitehall Street The mistake has caused several of my letters to be missent Please make the correction and put my name,

C Dunbar Roy,
Grand Opera House, Atlanta

Department of Public Health

East Las Vegas, N M, Nov 5, 1895

To the Editor —Will you please inform me where I can get a copy of the bill drawn up by a committee of the American Medical Association for the establishment of a department of public health?

Yours very truly,

W M Smith, Sec'y N M Med Soc

Answer —Write the Chairman of the Committee Dr Jerome Cochran, State Health Officer, Montgomery, Ala

BOOK NOTICES

Twentieth Century Practice An International Encyclopedia of Modern Medical Science By Leading Authorities of Europe and America Edited by Thomas L Stedman, M D, New York city In Twenty Volumes Volume IV Diseases of the Vascular System and Thyroid Gland New York William Wood & Company 1895

The contributors to this volume are Drs Bertrand Dawson, of London, Murray of Newcastle on-Tyne, Sansom, of London and Whittaker, of Cincinnati

The volume opens with a scholarly article by Dr Whittaker, on Diseases of the Heart and Pericardium, which occupies half of the book It is a complete work on the subject Diseases of the Blood Vessels, by Arthur Ernest Sansom, of London, is next taken up and occupies eighty-three pages, Dr Bertrand Dawson contributes an instructive article on Diseases of the Lymphatic Vessels, and the book is concluded by Dr George R Murray, with an exhaustive article on Diseases of the Thyroid Gland, including myxedema, cretinism exophthalmic goitre, and goitre On these subjects no authority stands higher than Murray

The book is fully up to the high standard of its predecessors, and with one-fifth of the work already accomplished, it is entirely safe to say that the "Twentieth Century Practice" will be a faithful exponent of the existing state of the practice of medicine at the beginning of the new century

Manual of Gynecology By Henry T Byford, M D Containing 234 *illustrations, many of* which are original 8vo, cl pp 488, price $2 50 Philadelphia P Blakiston, Son & Co Chicago The W T Keener Co 1895

This book is intended as a reference book for students at college, and as well for the general practitioner

Not quite thirty years have elapsed since the "Clinical Notes on Uterine Surgery" by Marion Sims ushered into the world a distinct surgical specialty, and what a flood of gynecologic literature has since been produced! The mere enumeration of authors' names would unduly crowd this page

Trained by his father, the late Prof Wm H Byford, one of the pioneers in gynecologic surgery, and with educational advantages the elder Byford did not possess, we might reasonably expect a carefully prepared manual, giving clearly and definitely the present tenets and practice In this we are not disappointed, and we can cheerfully commend the book

A Practical Treatise on Materia Medica and Therapeutics, with Especial Reference to the Clinical Application of Drugs By John V Shoemaker, M D, LL D Third Edition, thoroughly revised Slip 8vo, pp 1108 Philadelphia The F A Davis Company London The F J Rebman Co 1895

In this edition, the author has revised the text to conform to the nomenclature of the U S Pharmacopœia of 1890 and has added much new material Among the newer articles we notice mention of tolysal, tolpyrin, salocoll, salacetol, chlorphenol, bromphenol, ethylenediamine silver phosphate, tropacocaine, formaldehyde and formalin, dulcin and tannigen The antitoxins and serumtherapy, and the use of animal extracts have received appropriate mention

The author has made a careful revision, and has compressed a vast amount of information in the book but he seems rather frequently to have kept his own opinion in the background, when giving at length the opinions of the multitudinous authorities cited We regret extremely that the revision has not extended to the dosage The obsolete British system, which has not only disappeared from the U S Pharmacopœia, but which will not again appear in the British Pharmacopœia itself, still disfigures the pages of this otherwise excellent work on materia medica Notwithstanding this serious defect the work will be found one of the most useful for reference, and altogether creditable to the author The observations on the more recent additions to the materia medica are conservative and judicious

As regards pharmacologic remedies the author by no means restricts himself to those which are official Numerous substances, both of vegetable and mineral origin, not yet recognized by the pharmacopœia are discussed Some of these will no doubt be made official hereafter, and it must be a pleasant reflection to the author that so many drugs, of which he was the first to recognize the value have already become official after demonstration of their usefulness

---

NECROLOGY

Robert Battey, M D, of Rome Ga, November 8 He was born Nov 26, 1828, in Richmond Co, Ga, and was a son of Cephas Battey, a native of Peru, N Y His ancestors who were English, settled at Providence, R I He was educated at Augusta, Ga, and at Phillips' Academy Andover, Mass, and studied medicine at Booth's laboratory, Philadelphia, the Philadelphia College of Pharmacy, the University of Pennsylvania and Jefferson Medical College, graduating from the Philadelphia College of Pharmacy, March 17, 1856, and from Jefferson Medical College, March 7, 1857 He resided in Rome from December 1847, to the present time excepting the interval from November 1872, to October, 1875 during which he was temporarily at Atlanta, Ga, as professor of obstetrics in the Atlanta Medical College and editor of the *Atlanta Medical and Surgical Journal* He originated and successfully performed, in August, 1872, an operation for the removal of the ovaries, with a view to effect the change of life in women and thereby effectually remedy certain otherwise incurable maladies, an operation which has been many times repeated by himself and others He devised and used successfully in 1859 an improved apparatus for vesico vaginal fistula, and in 1872 he discovered that water introduced by the rectum, may be readily passed in the living body, the patient being etherized throughout the colon, the small intestines and stomach coming out at the mouth and he has repeatedly so passed it, as others after him have done, the entire practicability of doing it having been demonstrated upon the cadaver, at the Atlanta Medical College in December 1873, in the presence of the professor of anatomy and his class On June 3, 1869, he performed successfully the operation of perineal section (suggested by Prof Willard Parker, of New York), for chronic cystitis in a man of 62 In April, 1874, he successfully performed the new operation of vaginal ovariotomy, being the third instance of the operation In November, 1876, he removed from a man of 43 a fibro-cystic tumor of the carotid region, weighing four and a half pounds the patient making a good recovery in fourteen days He devised, in 1858, and has often practiced a new method of treating club foot by the use of carved wooden splints and roller bandage He was a member of the Georgia Medical Association, of which he was elected president in April, 1876, and of whose board of censors he had been chairman since April, 1873, the Atlanta Academy of Medicine, the American Gynecological Society, and American Medical Association, in which he was chosen a member of the Judicial Council in May, 1875, and secretary of the Obstetric Section at the same time as also in June, 1876 He contributed numerous essays and reports of cases to the various medical journals of the country In July, 1861, he was commissioned surgeon in the Confederate Army, serving as surgeon of the 19th Georgia Volunteers, as senior surgeon of Hampton's Brigade, as senior surgeon of Archer's Brigade, as surgeon-in charge of the Fair Grounds Hospital, number 2 at Atlanta, Ga, as surgeon in-charge of Polk Hospital at Rome, Atlanta, and Vineville, Ga, and at Lauderdale, Miss, and subsequently at Macon, Ga, until the close of the war

Joseph C Gilbert, M D, a prominent physician of large practice in Philadelphia died October 26, of apoplexy He was a native of this city and was born in 1832 He graduated from the old Pennsylvania Medical College in 1853 He served for three months as assistant surgeon in the 24th Regiment Pennsylvania Volunteers, and at his death was a member of Ellis Post No 6, G A R He was greatly interested in the development of his portion of the city and for six years represented the Twenty second ward in Councils

Joseph Daffron Schoales, M D, died in Philadelphia, October 24, of uremia He was born in Ireland Nov 27, 1837, and when 5 years of age the family immigrated to this country and settled in this city His father was the late Dr Marcus A Schoales Dr Joseph D Schoales was graduated by the Medical Department of the University of Pennsylvania in 1857 He served as surgeon to the Twelfth Pennsylvania Cavalry, until it was mustered out in 1865, except for a short period when he was detached for special service He was surgeon in chief at Harper's Ferry, under Colonel McReynolds and also under General Sigel when the latter made his raid through the Valley of the Shenandoah He was captured at Winchester, but after being prisoner of war for a month made his escape and returned to his regiment He was mustered out with the rank of Major and at once resumed practice in Philadelphia About thirteen years ago he was accidentally infected and afterward suffered with paralysis but continued in practice in spite of failing health until three years ago He was a member of the Philadelphia County Medical Society

Basil Norris, M D, U S Army, retired, at San Francisco, Cal, November 11, aged 67 Dr Norris who was retired with the rank of Colonel, was born in Montgomery Co, Maryland, March 9, 1828 He was graduated at the University of Maryland with the class of 1849 and entered the army as assistant surgeon in 1852 He served with the troops in Texas until 1857, in Utah until 1860 and in New Mexico until 1862 He was promoted surgeon in April, 1862, was appointed inspector of hospitals in October 1862, and Medical Director of the left grand division of the Army of the Potomac in February, 1863 and subsequently attending surgeon at Washington He was brevetted Lieutenant Colonel for faithful and meritorious service during the war and subsequently promoted to the rank of Lieutenant Colonel and Colonel When retired he was Medical Director of the Military Division of the Pacific His writings were numerous and scholarly He was a genial companion an accomplished officer and a faithful friend Few men connected with the public service had a wider circle of friends and acquaintance

PUBLIC HEALTH

The State Board of Health of Michigan has published an abstract of a commendatory notice of their course in regard to popularizing hygienic knowledge and inculcating sanitary precepts with a view to the extinction of zymotic diseases by means of pamphlets etc which appeared in the *Journal d'Hygiène* Paris, France, October 10

Michigan State Board of Health —The circular of the Michigan State Board of Health on the prevention of typhoid fever has been issued The pamphlet contains the following mortality source of infection mode of communication, the protection of the water supply, period of incubation, the duties of householders and physicians, duties of local board of health and health officer precautions, disinfection of the bowel discharges of the sick, disinfection of urine, clothing, towels etc , bodies of the dead, disinfection of rooms, privies, etc

Diphtheria at Newark, N J —By reason of the great prevalence of this disease at Newark, the common council has after much contention granted to the Board of Health the sum of $2500 The City Hospital also receives an additional grant of $1000 to tide that institution over the present crisis A protracted and bitter dispute has taken place between the mayor of the city and the health authorities over the expenditures of the latter Some physicians assert that the disease can be traced to the promiscuous use of drinking cups in public schools, and contend that the school board should cooperate with the health board to abolish this practice There were reported in Newark in October 183 cases of diphtheria, 84 more than in September

Contagious Disease Hospitals Compared to the Fire Departments of Cities —Dr William Smith, President of the recent Sanitary Congress at Hull, England, in his address took occasion to congratulate that city upon the establishment there of an admirable infectious disease hospital, the provision for smallpox patients and the ship for the isolation of cases of cholera It might occur to some of the ratepayers of Hull that if these hospitals were not used, there was something of a reason for abolishing the cholera and smallpox hospitals or at least making some other arrangement by which the expenses attendant on their maintenance were to be somewhat abated He hoped that if any such idea existed in the minds of any, that they would once for all get rid of it They really must look upon them as a provision made, as it were, in times of peace for war and for the trouble which might come upon them at any moment The provision of those hospitals was as necessary as fire stations It would be almost as reasonable to expect to organize a fire department anew, in the face of each new conflagration in our cities, as to be in the attitude of some communities that put off the organization of their hospital for infectious diseases "until the actual demand" for them

Etiology of Epidemic Cerebro-Spinal Meningitis —In 1887 Weichselbaum described a parasitic microorganism which he claimed was pathogenic for cerebro-spinal meningitis and which from its habitat he called *diplococcus meningitidis intra cellularis* His observations which were confirmed by Goldschmidt, Marchiafava, Celli and other bacteriologists, have been energetically discussed since, both in France and Italy A number of authors, and among them Bordoni-Uffreduzzi, claim the microorganism described by Weichselbaum is nothing but a variety of the pneumococcus In order to settle this question Jaeger,[1] during a small epidemic of this disease in Stuttgart, made some anatomic and bacteriologic researches He separates the Weichselbaum diplococcus from the Frankel coccus, through morphologic characters The former does not have the elongated lanceolate form of the pneumococcus, it is more rounded, and when joined to another, looks something like the sole of a shoe The capsule surrounding it is much less developed, and very often is difficult to recognize In pure cultures the diplococcus of Weichselbaum, like the pneumococcus, often takes the form of small chains, but very often also it is grouped in tetrads which are never seen in Fränkel's coccus, it is more of a tetracoccus than a diplococcus These differences extend to their biologic characteristics also, the intracellular coccus is much more resistant It is never pathogenic in subcutaneous injections, it must be introduced into the serous cavities as the pleura or peritoneum in order to cause morbid phenomena Jaeger looks upon the intracellular coccus as the true pathogenic agent of epidemic cerebrospinal meningitis The pneumococcus plays a much less marked role, to be sure it is found in some cases but we find streptococci and other microbic agents in them also These cases are nearly always isolated sporadic ones It is fair to suppose that in the cases of epidemic meningitis where the pneumococcus is found, we have to do with examples of mixed infection The mode of transmission of this epidemic form of meningitis is still but little known[2] However, the presence of the intracellular coccus in the nasal secretions, and its persistent virulence in the dried mucus throw some light on the propagation of the disease The pathogenic microbe is disseminated by the nasal secretions soiling the linen and clothes of the patient, or by the sputum, and thus produces the almost murderous epidemics

A Berlin Oekonomierath's Dairy —The *Public Health* (London) reports the persistent agitation of the pure milk question that is going on in official and private circles in London From a recent report of the Royal Commission appointed to inquire into the effect of food derived from tuberculous animals on the health of human beings, many lessons are to be learned regarding the nicety and scientific precautions that obtain in some of the German and Danish dairies In one or more of the German dairies the milk is filtered through three layers of fine gravel, and it is impossible for the inexperienced person to realize how much dirt is collected by this process A condensed statement taken from the Report of the Royal Commission, concerning one of the leading Berlin establishments is as follows

The *Milch Kur-anstalt* of Herr Oekonomierath Grub, situated at the Victoria Park, in the southwest of Berlin, is designed solely to provide milk of the first quality for children and invalids No cream, butter, or cheese is made Stalls for 250 cows are provided, they are lofty and well-ventilated, the floor is made of cement, and the walls, to a height of eight feet, are covered with white glazed porcelain tiles Dried peat serves to absorb the excreta, and prevents any unpleasant smell Only such animals as come from the healthiest breeds (chiefly the Swiss) are bought, and, as a rule, they are not kept for more than one year No animal is accepted without the district veterinary surgeon's certificate as to its healthy condition, and before its milk is utilized, it is placed in an observation stall for some days, under the control of the company's own veterinary surgeon, who regularly examines all animals in the institution As food stuffs, only hay from the Jura Alps and wheat meal are allowed Brewers' grain, various oil cakes, and even grass are excluded Before milking, the udder is carefully washed, and the milk is received into pails made out of one piece of metal with no sharp angles Great stress is laid on the importance of removing as quickly as possible from the cow shed the milk that is drawn, and therefore, as soon as five or six pails are full they are removed, and the milk is cooled down by a Laurence cooler The liter bottles, previously having been cleaned by washing in a soda solution and brushing (the latter operation being materially assisted by introducing a little sand), are then filled, stoppered by a patent porcelain cap, stamped with a leaden stamp, and dispatched to the city twice daily A large business is also done in the preparation of sterilized milk, for which the arrangements are exceedingly good The sterilizer is capable of holding 600 bottles at a time, and these, when filled, are placed with the porcelain cap, with its india-rubber col lar loosely fixed, in the apparatus The temperature in the interior is maintained for an hour to an hour and a half at between 90 and 100 degrees Cent This *Milch Kur anstalt* no doubt owes much of the success it has attained to the way in which it is supported by the medical profession, some of the best known members of which have allowed their names to appear as references "

[2] La Sem Medicale, 1895 No 48

Sanitation in India —The following rules for combating epidemics of cholera in municipalities of the Madras Presidency were recently framed by a committee consisting of the Honorable C S Crole, Surgeon Major-General C Sibthorpe and Surgeon Lieutenant-Colonel W G King, appointed by the Government of Madras These rules are not intended for introduction into Madras city, and will for the present apply only to the twenty-four mufassal municipal towns It is the object of these rules to insure 1, that the earliest possible information of every attack of cholera should be conveyed to the authorities, so that the cholera microbes may be at once prevented from being conveyed into situations in which they might spread the infection , 2, that the microbes should be at once completely destroyed , and 3, that medical assistance may be provided for those who, in spite of precautions, are attacked by the disease They accordingly follow these three divisions Municipal councils shall be responsible for the general carrying out of this scheme and district medical and sanitary officers for the detailed working of the rules The latter shall make their own arrangements both in their headquarters and elsewhere in the district, except in municipalities where there are civil surgeons In these, civil surgeons shall be responsible For the purpose of these rules, every municipality to which they apply shall be divided into "circles" comprising from 2,000 to 3,000 houses containing from 7,500 to 10 000 inhabitants These circles should, as far as possible, follow ward divisions or other local limits so that they may be readily comprehended Three circles shall form a 'division " Chairmen will at once map out their towns into 'circles" and 'divisions," and after approval by the collector, record the maps in their offices, and send a copy to the senior medical officer of the municipality For each division of 22,500 to 30,000 inhabitants, the chairman shall at once procure and retain in the municipal stores the following apparatus and disinfectants

	Rs	a	p
12 portable tin canisters for disinfectants at Rs 1–8	18	0	0
9 lb perchlorid of mercury at 3 annas an oz	27	0	0
9 lb commercial hydrochloric acid at 2 annas per oz	18	0	0
60 lb carbolic acid at 4 annas per lb	15	0	0
600 lb of sawdust and 600 lb of unslaked lime at 1¾ pies per lb	8	5	4
Total	86	5	4

He will be responsible that these stores are always maintained and in good condition Should it appear to the collector of the district that cholera imminently threatens to attack any municipality to which these rules apply, he shall warn the chairman of the council and the district medical and sanitary officer and the senior medical officer of the town accordingly Upon receipt of such warning the chairman shall immediately appoint in each circle of the town an observation staff consisting of

	Rs	
One inspector on	15	per mensem
One peon on	8	
One toty on a maximum of	7	

and in each division a divisional inspector on Rs 35+15 jutka or horse allowance with an orderly on Rs 8 The orderly should be allowed a jutka or pony to enable him to carry without delay such orders to circle inspectors as may be given The chairman shall without delay report to the collector the date on which these appointments were made This staff should be drawn from the existing sanitary establishment of the municipality, as their local knowledge will be valuable, and the vacancies so caused should be filled by temporary hands who should be paid at the rates sanctioned for that establishment It will be the duty of the members of the observation staff to constantly and systematically patrol the whole of their circle in order to gain intelligence of the first case of cholera or severe diarrhea in it so that immediate action may be taken At such times cases of severe diarrhea should be regarded as equally dangerous with cholera The members of the observation staff should also be employed in removing with the aid of the ordinary conservancy establishment, all defects in sanitation which would favor the multiplication of the cholera microbe, such as decaying rubbish or stagnant sewage, and should report their action to the chairman They should further warn the inhabitants of the circle to adopt the precautions against cholera prescribed in the extract from Surgeon Lieutenant Colonel King's "Simple Sanitary Rules" which is printed as an appendix to these rules, and should distribute copies of this, which the chairman will keep ready printed in the vernacular, gratis, and as widely as possible The chairman and councilors and municipal servants of all ranks should assist the observation staff in every way possible, and the police in every way compatible with their other duties, both in getting information of the first attack and in removing sanitary defects in the circle

On receipt of information under the above system of the first attack of cholera, the chairman shall at once employ in the circle in which it has occurred (but not in other circles) the following additional staff three peons on Rs 8 each three toties on a maximum of Rs 7 each and shall report to the collector and the district medical and sanitary officer the date on which he did so This staff, like the observation staff, shall be selected from the ordinary existing municipal establishment, the vacancies so caused being filled by temporary men on the sanctioned rates, and it shall be combined *with the observation staff of the circle so that the whole may thenceforth form ' a preventive staff " to carry out the duties set forth below* The preventive staff shall visit every house in which cholera has occurred and shall use the greatest care in seeing that all choleraic vomit and excreta are at once collected in separate vessels, mixed with carbolic sawdust,[1] paddy husk or other combustible matter, and where necessary with kerosene oil, and thoroughly, completely and immediately burnt on or near the premises The burning shall *invariably be carried out in the sanitary inspector's presence and he shall be responsible that it is thoroughly done* The chairman shall delegate to the senior medical officer of the town his powers under section 231 (i) of Act iv of 1884 of entering and inspecting houses Rags, clothes and bedding stained with vomit or excreta should similarly be burnt upon the spot under the same precautions, the danger of keeping such articles being fully explained to the owners and full compensation in money or kind being offered in the case of the very poor Floors and furniture stained with the vomit or excreta should be disinfected by being thoroughly sprinkled with a solution of perchlorid of mercury made up as shown in the note[2] The burning of tar and sulphur in houses and streets should be discontinued as it is inefficient as a disinfectant, but street drains outside the houses attacked should be flushed with the given solution[3] The greatest courtesy and consideration should be used by the preventive staff to all classes in carrying out these instructions, as the exercise of extreme tact is essential to the success of the scheme After a patient has recovered, the house and especially the room which he occupied during the attack, should be thoroughly disinfected The floors should be dug up wherever stained with choleraic matter and the earth burnt The floor and the house drains and the furniture should also be liberally sprinkled with the solution above described[4] The chairman shall provide the medical officers responsible for working the rules with a permanent advance of Rs 50 per division, which shall be recouped from time to time by bills supported by vouchers where possible The preventive staff shall continue to be maintained in an affected circle for ten days after the last attack of cholera in it and the observation staff in all circles for twenty-one days after the last attack in the town During this time they should be employed in remedying sanitary defects There shall be a headquarters in each division at which a medical subordinate shall reside who shall be supplied with medicines, and medical comforts from the municipal hospital for the treatment of those attacked and who shall be available for attendance gratis on the sick in their own houses This shall also be the headquarters of the division inspector and of the preventive staff on night duty In one place at least in each town there shall be isolation huts with separate accommodation for males and females for the treatment of those who desire it or who are brought there These shall be in charge of a medical subordinate with the necessary staff and supplied with equipment medicines and medical comforts This subordinate shall be deputed to no other duty He shall reside with his staff on the spot and shall be adequately paid No charge for medical treatment under these rules shall be made [illegible] the treatment in the huts or under Grant Hospitals and Dispensaries The headquarters of the division and the sites for the isolation hospitals shall be at once selected and shall be marked on the maps referred to above In order to make provision for meeting the charges under those portions of these schemes relating to observation and prevention the council of every municipality to which these rules apply shall be required to allot in every budget under the head of charges a sum which shall be in the proper [illegible] of Rs [illegible] for every [illegible] inhabitants in the municipality This shall be called the cholera reserve and shall not be spent upon any object but the carrying out of this scheme [illegible] The provision of this reserve should not be allowed to disturb the existing percentages to the total income [illegible] of the expenditure upon communications, education, [illegible], etc, or to swell the total of the [illegible] for sanitary purposes under Grants [illegible] and [illegible] but should be set aside from funds which [illegible] annually expended upon permanent (as distinguished from temporary) sanitary needs Municipal [illegible] are hereby authorized to employ establishments on these lines [illegible] laid down as the necessity for them arises, and to defray the charges from the cholera reserve in anticipation of the sanction of Government but this sanction should be obtained without delay On the final withdrawal of the special staff the medical officer responsible for working the rules shall within seven days forward a report on the epidemic and the operation of the rules through the chairman of the municipality to the collector for the orders of Government In cases where the medical officer in question is subordinate to the district medical and sanitary officer or the civil surgeon, such report shall be forwarded through those officers In every case such communications shall be submitted to Government through the sanitary commissioner —*The Indian Medico-Chirurgical Review*, September 1895

---

[1] One part of carbolic acid to ten parts of sawdust

[2] ½ oz perchlorid of mercury
1 oz hydrochloric acid
Three gallons (one small chatty full) of water with a pinch of red ink powder to color it to prevent accidents

[3] Wooden buckets or earthen pots should alone be used for carrying about this solution as it destroys metal vessels and the packets of the solid perchlorid should be labelled Poison in English and the vernacular and only intrusted to the inspectors themselves

[4] It is most desirable that the excreta of a patient for [illegible] days after he has recovered from an attack should be carefully collected and carried away They still contain cholera microbes For this purpose a Dindigul bullock lorry costing Rs [illegible] and air-tight iron excreta drums costing Rs [illegible] each may be provided The purchase of these will however be left to the option of councils

The Chicago Drainage Canal —Final Report of Sanitary Inspector —At the meeting of the Board of Trustees of the Sanitary District of Chicago, the clerk presented a report from Dr William Martin Sanitary Inspector, with reference to sanitary conditions along the main channel, and tendering his resignation of his office and the report was read and referred to the Committee on Public Health and Order The following is the communication

CHICAGO, Oct 29, 1895

To the Honorable the Board of Trustees of the Sanitary District of Chicago

Gentlemen —In making this, which I intend shall be my last report, I shall take occasion to review the work done in this department, and state the conditions existing at the time of assuming charge, which necessitated the appointment of a Sanitary Inspector

Soon after the inauguration of the work in the fall and winter of 1892, it was discovered that a great deal of sickness was prevalent in the various quarters along the channel where the men were housed and fed This arose entirely from the wretched sanitary conditions surrounding these places, and was of such a threatening character as to call for prompt action on the part of the Trustees in order to guard against epidemics which were liable to occur at any moment unless a radical improvement was secured in this respect Numbers of these places were located in low swampy spots, abounding in malaria, with no facilities whatever for proper drainage The bunk houses were poorly constructed and very much overcrowded The water was very impure and no adequate provision was made for the proper disposition of camp sewage As a natural sequence sickness was quite prevalent, and as there was no organized system for the medical care of the laborers, they were in a most wretched condition, were they so unfortunate as to fall ill After my first thorough inspection of the entire line and the submission of my report, the recommendations therein made were promptly acted upon and a number of sanitary regulations adopted, designed to correct the evils to which I had called attention Cards on which these rules were printed were ordered to be posted in all of the quarters and instructions sent to each contractor that these regulations must be rigidly enforced Having discovered that there was no law in Illinois bearing on the subject of overcrowding in lodging houses, this Board was instrumental in having the State Board of Health pass a resolution in which was clearly defined the minimum air space that each lodger is entitled to, this being the first time in the history of the State that any such regulation was enacted No provision having been made for the care of the sick and injured among the employes on the work, a plan had to be devised that would meet this requirement This was done by an assessment of 2 cents a day on each man for hospital fees for which sum a number of physicians living along the line contracted to take care of them in hospitals owned by themselves or in the hospitals of Chicago and Joliet with the authorities of which they had arranged for such treatment Suitable means of conveyance being employed to transport patients to these various hospitals this plan has seemed to work well and has secured good medical and surgical attention at a very trifling cost to the laborers By strictly enforcing the regulations in regard to the supply of wholesome water, a proper disposition of camp sewage, overcrowding of bunk-houses, and an abundant supply of substantial well cooked food, we have been successful in keeping the camps free from epidemics of disease, which is always a danger to be apprehended where large bodies of men are being cared for on great works of this character As proof of our success, I would cite the fact that during the prevalence of smallpox, which prevailed in Chicago during the year 1893 and 1894 there occurred on the drainage channel a total of sixteen cases only This, when we consider the fact that the majority of the laborers who came from the city were accustomed to live in the cheap lodging houses, which were regular hotbeds of contagion, was a very flattering result, and was only achieved by the most thorough systematic vaccination of all the workmen on the line, compelling them to submit to it or seek employment elsewhere Numerous analyses have been made of the drinking water furnished the men, in order to insure the purity of what is usually one of the most prolific causes of disease Where such impurities have been detected, prompt measures have been adopted to correct such evils which have resulted in warding off danger from this source The work of inspection has been materially aided by the police force of the Sanitary District, who are under orders to report any negligence on the part of the contractors pertaining to sanitary matters That they do the work well is attested by numerous reports made to me, which are on file in my office A great deal of misapprehension seems to exist in the community at large in regard to the powers of the Board of Trustees, as it relates to the control of all matters pertaining to health and public order as applied to the laborers on the canal It is generally believed that their power is absolute, when the facts are that it is very limited The law gives them the power of controlling the various camps in regard to keeping them in a proper sanitary condition, but they have no control whatever as regards the care of the sick and injured men, which is a matter resting entirely with the contractor who employs them Some undeserved criticism has been made of this Board as well as myself, in connection with this subject, probably through misapprehension on the part of the critics, and not with any design of placing this Board in a false position for I think it can be truthfully said that in all matters pertaining to the health, physical and moral well-being of the laborers employed on the channel, the Trustees have ever been thoroughly impressed with their duties and active in the discharge of them In a work so extensive as this, ideal conditions can not be maintained in all things, but taken collectively, there is a higher average of conditions favorable to the laborer than was ever known on any public work of corresponding magnitude I had occasion during year of the World's Fair to meet travelers from various parts of the world who had seen the other great canals during their period of construction, and they all united in the opinion that our men were better fed, better housed, and in every respect better cared for than anything they had witnessed on the Suez the Panama, German and Manchester Canals, or on any of our own great railroads

(Signed) WILLIAM MARTIN, M D,
Sanitary Inspector

Health Reports —The following health reports have been received by the Supervising Surgeon General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Arkansas Mississippi Co , November 6, 43 cases, 2 deaths
Louisiana New Orleans, October 5 to November 2, 7 deaths
Michigan Smallpox reported present at Detroit, Hamtramck Twp , Rochester

Southampton October 19 to 26, 1 case
Teneriffe September 21 to October 5, 2 cases, 1 death
Trieste October 18 to 25, 1 case
Tuxpan October 19 to 26, 3 cases,
Zurich October 12 to 19, 1 case

YELLOW FEVER

San Juan de Puerto Rico October 5 to 12, 10 cases, 1 death
Rio de Janeiro October 5 to 12, 3 deaths
San Salvador, November 1, yellow fever reyorted

CHOLERA

Bombay October 1 to 8, 2 deaths
Osaka and Hiogo October 5 to 12, 7 cases, 7 deaths
Japan total cholera statistics from date of outbreak to Oct 10, 1895 cases 52,218, deaths, 36,075 During the week October 3 to 10 1,279
Cases of cholera occurred on Japanese army transports occupied in the movement of troops from and in Formosa

MISCELLANY

Association of Assistant Physicians of Hospitals for the Insane.—The second meeting of the Association of Assistant Physicians of Hospitals for the Insane was held at the Michigan Asylum for the Insane, Kalamazoo, Mich , Oct 24, 1895 The membership originally composed of medical officers of the staffs of asylums of Michigan, Illinois and Iowa, was extended to include the assistant superintendents and assistant physicians of all asylums The next meeting will be held at the asylum at Independence, Iowa, during May, 1896

Mr Edison's Definition of Electricity —A New Jersey paper quotes " the wizard" Edison as offering the following definition " Electricity is a mysterious fluid about which nothing is known " Certainly, if any one could tell what electricity is, Mr Edison would seem to be the man He frankly acknowledges entire ignorance of it He knows undoubtedly a multitude of ways in which it manifests itself, and he has been marvelously successful in utilizing those manifestations But of the force itself he knows nothing

Horseless Vehicles for the Country Physician —The *Popular Science News* has the following note regarding a new form of horseless carriage

' Self propelling carriages are being introduced from France where they make a speed of eight to fifteen miles an hour on the level The motive power is a gasoline engine, which occupies little space and carries sufficient petroleum spirit to last for a run of fifty miles, other kinds use electricity etc There are hundreds of these carriages in France Country doctors find them useful, and as the engines are noiseless horses are not frightened by them "

But France has well drained, macadamized roads Deep mud, such as we encounter in our country roads, is too much of a hindrance to the operation of the vehicle

Massage an Occupation for the Blind —From *Popular Science News* ' It is stated that in Japan, massage is practiced almost exclusively by blind persons The idea is that the sense of touch is so much more delicate and developed in those who have lost their vision, that the employment of them as masseurs and masseuses is quite in accord with the natural fitness of things Blind persons are largely used for this purpose in St Petersburg and at a massage school there the professor is also blind Doubtless, were our massage establishments officered by blind male and female persons the suspicion raised against them that they were used for improper purposes would soon be removed "

Tubercular Disease of the Portio Vaginalis —In the *British Medical Journal*, Dr J D Williams has reported two cases of the above named affection In the first of these cases, the patient was 63 years of age and the subject of phthisis from which she died a few weeks after being brought to the hospital The genital organs, removed at the autopsy, showed a tuberculous affection of the cervix involving a portion of the adjacent vagina There was no tubercular disease of the body of the uterus nor of the appendages The second case was that of a patient 36 years of age She showed some disease of both apices On the cervix an irregular ulcer was to be seen, which, on microscopic examination, proved to be of a tuberculous nature The cases are of interest from the location of the lesion The cases bear out the observation made by others, that in cervical tuberculosis the body of the uterus and the appendages usually remain free of disease

Practice of Veterinary Science made Amenable to Law in North Dakota —An act has been passed in North Dakota regulating the practice of veterinary medicine, surgery or dentistry in that State It provides for the appointment of a board of examiners, the issuance of certificates, and makes it a misdemeanor punishable by a fine of not less than fifty dollars nor more than one hundred dollars, to practice in violation of this law But an exception is made where gratuitous services are rendered in cases of emergency, dehorning of cattle, and castration of animals All persons beginning the practice of veterinary medicine, surgery or dentistry in the State, after the passage and approval of this act, must be graduates of a legally authorized veterinary school, college or university, and they shall subject themselves to such examination as the board may require Any person complying with the provisions of this act shall be entitled to expert fees as a witness in all cases relating to the veterinary profession in any court of law or equity

A Case of Umbilico Vesical Hernia —According to *La Semaine Medicale*, August 21, Dr Lannelongue reported to the Congress of Gynecology, Obstetrics and Pediatrics recently held at Bordeaux, the following interesting case some years ago a woman brought to him a male infant, aged three months, which passed water, both through an umbilical appendix resembling a penis, and by the natural organ, which was in its proper place The jet which came from the umbilical canal described a curve more than 30 centimeters in diameter On examination, it was found that the apparent abnormal pelvis was an umbilical hernia caused by the persistence of the urachus A urinary fistula had been produced on the separation of the umbilical cord The child subsequently died and the author had an opportunity to make a necropsy The bladder was injected and it was then seen that the viscus was prolonged by a channel as large as the forefinger, namely the urachus, up to the umbilicus The channel extended into the external appendix where it opened by an oblique orifice resembling the meatus urinarius The contractions of the bladder in micturition caused a stream in both directions, umbilical and urethral hence the double jet of urine seen from time to time this however, was exceptional as the musculo-elastic ring of the umbilicus fulfilled the function of a sphincter and prevented the escape of urine through that orifice The author suggests that this case once more shows the necessity of tying the umbilical cord only after having satisfied oneself that there is no hernia at the proximal end

Burns Treated by Strong Carbolic Acid Dr Benjamin H Brodnax of Brodnax, Louisiana, writes to the *Popular Science News* as to above bold line of treatment of burns and scalds "Take pure undiluted carbolic acid, with a feather or fine brush paint the burned or scalded surface, extending a little over the edge where the wounded surface is not bare Pain instantly ceases and if care is taken no further dressing is required but a light tissue of lint cotton and one roll of bandage will insure from contusions etc" Dr O H Allis who read the original article, sent him by myself before the Philadelphia County Medical Society March 10 1891 remarked To my mind it is one of the boldest ventures in all surgery To think of applying to a raw and agonizing burn that which would scald a healthy cutaneous surface would seem to the unreflective mind a reckless and cruel act But when we consider that a raw burned surface is painful from its exposed nerve filaments and that the strong acid combining with the albumin of the tissues forms a coating that excludes the air while at the same time it benumbs—paralyzes—each terminal exposed filament, the remedy seems to be the result of a happy inspiration"

Fifteen Thousand Pasteurian Treatments—The Record of Nine Years—The last annual report of the Pasteur Institute embraces the ninth year of its operations, and shows in that time the grand total of 15,217 persons treated The mortality, excepting those cases that were considered to be in a hopeless state at the time of reception, was eighty one deaths, or a mortality rate of a little over one half of 1 per cent The lowest the rate of mortality has touched in any one year was a little more than 2 per 1000 and the rate has shown a marked decline in recent years compared with the years immediately following the establishment of the Institute Whatever may be our hesitancy—natural or acquired—regarding institutional statistics the following may be taken as conclusive testimony of one of the greatest conquests over disease that has yet been made In 1886, number of persons treated 2,671 deaths 25, rate of mortality per cent 0 94 In 1887 number of persons treated, 1,170, deaths 14, rate of mortality per cent 0 79 In 1888, number of persons treated, 1,622, deaths, 9, rate of mortality per cent, 0 55 In 1889 number of persons treated, 1,830 deaths, 7, rate of mortality per cent 0 38 In 1890 number of persons treated, 1,540, deaths 5, rate of mortality per cent 0 32 In 1891, number of persons treated 1,559, deaths, 4, rate of mortality per cent, 0 25 In 1892 number of persons treated, 1,790, deaths 4, rate of mortality per cent, 0 22 In 1893 number of persons treated, 1,648, deaths, 6, rate of mortality per cent 0 36 In 1894, number of persons treated, 1 387, deaths, 7, rate of mortality per cent, 0 50

Statistical and Sanitary Notes from the Military Department of the Platte—Colonel Dallas Bache, assistant surgeon general U S Army, states in a recent circular that it is his intention, as medical director of the Department, to issue for each month a statistical and sanitary note "for the purpose of distributing a class of information which is of equal interest to himself and the medical officers of posts It is not intended to institute close comparisons between local statistics, into which different factors must enter, but to associate all the medical officers in the Department in matters of general concern, and to supply them at short intervals with intelligence which is now a subject of annual report" The form used by Colonel Bache gives the name of each post, its mean strength, the admissions for disease and for injury, the number inefficient daily, the deaths and discharges, and the admissions and constant sickness as percentages of the strength Under date Oct 30, 1895, Nos 1, 2 and 3 of these "Notes," for July, August and September respectively, have been published Fort Omaha, Nebraska, has the highest admission rate for each of the months, 17 83 per cent of its strength in July, 13 89 in August and 16 24 in September Fort Meade, South Dakota, has, on the whole the best record, its admission rate for disease in July having been only 4 59 per cent of its strength, in August 4 74 and in September 3 75 Nothing of separate sanitary interest was reported during the first two months, but on the September report it is noted that up to the end of the month no case of typhoid fever had been reported in the Department A large part of the command was in the field on practice marches and at target ranges During their field service the health of the troops was excellent

The Army Medical School—The second session of this school will begin Monday, Nov 18, 1895, Colonel C H Alden, president of the faculty, delivering the opening address The regular course will consist as heretofore of lectures on the duties of Army medical officers in peace and war, on military surgery, military medicine, and military hygiene with practical laboratory work in bacteriology and sanitary chemistry, hospital corps drill and first aid, horsemanship and the details of military inspections, parades and other ceremonies Some changes have been made in the faculty recently on account of the retirement from active duty, at his own request after thirty years of service, of Lieut-Colonel John S Billings, who held the professorship of military hygiene, and of the assignment to other duty of Captain J M Cabell, who was assistant to the professor of military surgery and instructor in hospital corps drill and company administration Colonel C H Alden, assistant surgeon-general, will continue to instruct the young officers in the duties of Army medical officers Lieut-Colonel W H Forwood, deputy surgeon general, professor of military surgery, is understood to have made arrangements for practical work on the cadaver, a feature which was not embodied in the program of the first session of the Army Medical School As the Examining Board had every facility for ascertaining the qualifications of the candidates accepted by it, the addition of this to the curriculum evidently means that it was not satisfied with the surgical skill displayed by the last graduates who came before it Lieut-Colonel D L Huntington, deputy surgeon-general, has been appointed professor of military medicine, relieving Major Charles Smart, surgeon, who succeeds Lieut-Colonel Billings in the chair of military hygiene and continues to hold position as director of the chemic laboratory Major Walter Reed, surgeon, has been announced as professor of clinical and sanitary microscopy and director of the pathologic laboratory, and Captain F R Keefer, in command of the hospital corps company at Washington Barracks, D C, has been appointed assistant to the professor of surgery and instructor in hospital corps drill The day's work of the student begins, except on Saturdays, with medico military drill, the forenoon, according to the program, is to be spent over pathologic and bacteriologic microscopy; the afternoon in the work of the sanitary chemist with a lecture from 3 to 4 P M Arrangements have been made for special lecture courses by Major Geo B Davis, judge advocate, U S A, on military law, by Dr Godding, superintendent of the St Elizabeth Hospital, D C, on insanity, by Professor C W Stiles, Department of Agriculture, on the parasites of the human system, and by Dr Robert Fletcher on the present condition of the Army Medical Museum and Library and the methods of literary research The program requires the class to report on Saturdays to the Commanding Officer of the cavalry post of Fort Myer, Virginia, who will place its members under the care of a competent instructor in the riding hall The lecture hour on alternate Fridays will be given up to the meetings of the Journal Club, which was organized in 1893 with a view to giving the young men opportunities of speaking in public and familiarizing them with the methods of medical societies The following is a copy of the by-laws of the Club, adopted during the first session of the Army Medical School

1 The name of this Association shall be the Army Medical Journal Club

2 It shall be composed of the Medical Officers of the Army on duty in Washington or its vicinity, and of such other physicians as may be invited by the Surgeon General of the Army, or by the President of the Club, to take part in its proceedings

3 The objects of the Club are the mutual benefit and instruction of its members, by the reading of brief abstracts of important articles in medical journals, the examination of new books, apparatus specimens, etc, acquired for the Army Medical Library, Museum and School, and such other methods as may, from time to time, be determined on

4 The officers of this Club shall be a President and a Secretary, to be elected at the first meeting in November of each year

5 The meetings of this Club shall be held in the lecture room of the Army Medical School, on alternate Fridays, from October 1 to May 1, beginning at 4 P M

6 The members of the Club shall be called upon in alpha-

betical order of their names, for summaries of journal articles, it being understood that no one shall occupy more than fifteen minutes and that the total length of the meeting shall not exceed one hour and a half It is supposed that from six to eight persons will be called on for journal abstracts at each meeting

The first meeting of the Army Medical Journal Club for the season of 1895 96, will be held at the lecture room of the Army Medical School cor 7th and B Streets, s w , on Friday, November 22, at 3 P M

Hospital Notes

The contract for the erection of the new Moline, Ill , public hospital has been awarded The total cost of this institution will be $20,000 ——By the will of Captain Lang, who with his wife was murdered in Gardenville, Md , November 4, his estate, valued at $200,000, is left to the St Joseph Hospital at Baltimore ——The Chicago Hospital was formally opened November 9 ——The regular annual meeting of the Waukegan, Ill , Hospital Association was held October 21 ——The annual report of the Maine General Hospital at Portland, shows that 1,061 patients were treated during the year

Washington Notes

Health of the District —The report of the Health Officer for the week ended November 2 is as follows the number of deaths reported at the health department during last week was 116 In the previous week they numbered 118 The relative conditions in regard to general health were quite similar during the two weeks, the exceptions being diseases of the brain and typhoid fever The mortality from brain maladies rose from 10 to 19, and that from typhoid 10 to 17 One death each from diphtheria and smallpox occurred Otherwise no deaths from any of the contagious diseases were reported The infant mortality declined from 39 to 22, while the total death rate declined from 22 27 to 21 90 There were 93 births and 58 marriages reported , 25 deaths occurred in hospitals and 13 were reported by the coroner

Election of Officers in the Post-Graduate School of Medicine —The board of incorporators of the Post-Graduate School of Medicine of the District of Columbia held a meeting at the office of Dr Samuel Busey on the 5th inst and elected officers for the ensuing year as follows President, Dr Samuel C Busey First Vice President, Dr J Ford Thompson , Second Vice-President, Dr W W Johnston , Secretary, Dr G Wythe Cook, and Treasurer, H L E Johnson The following committees were appointed Curriculum, Drs James Kerr, S S Adams, Edward L Tompkins, W H Wilmer and E M Parker , Executive, Drs H L E Johnson G N Acker and Thomas E McArdle The constitution and by laws as drafted by a committee consisting of Drs H L E Johnson, W H Witmer and E L Tompkins were adopted

Medical Society of the District —At the meeting of the society held on the 6th inst , Dr T O Belt read an essay on ' Consanguineous Marriage as a Factor in the Causation of Disease " This valuable contribution to science brought out a discussion which occupied the entire evening and was participated in by Drs Butler, Shoat, Ritcher, Loring, Berman, Kleindschmidt, Chappell, W W Johnston, H L E Johnson, S S Adam and Ward

Detroit Notes

The Board of Health has given notice to the profession that the following cases are to be reported and placarded for quarantine smallpox, varioloid, typhus fever, Asiatic cholera, diphtheria scarlet fever, measles, glanders or farcy in man and wherever known in horse, and membranous croup That typhoid fever, chickenpox and whooping cough are to be reported, not quarantined or placarded The Health Officer on account of the spread of diphtheria has asked the Board to appoint physicians to examine the throats of all children attending the public schools , and when one is found suffering with sore throat, it is to be noted and the case followed to its home, so as to prevent as much as possible the spread of diphtheria

The Health Office Report for week ending Nov 9, 1895, shows deaths, total 140 , under 5 years, 37 Births, male 55, female 45, total 100 The contagious diseases for same period diphtheria, last report 41 new cases 37, recovered 24, died 11, now sick 43 Scarlet fever, last report 9, new cases 5 recovered 2, died 1, now sick 11 Smallpox, last report 1, new cases 1, recovered 1, died none , now sick one The death list has been swelled by the awful disaster that befell the *Detroit Evening Journal* Building, in which several minor manufacturing concerns were established This building was entirely destroyed by the boilers exploding, and resulted in the death of thirty seven people, men, women, boys and girls, and a considerable number of injured and burnt Some idea of the nature of the ruins can be arrived at when it is known that the last body to be removed from the *débris* had lain where found for fifty-nine hours, and was buried under tons of brick, stone and iron, and nearly all this time, night and day, the city had many of its laborers with horses removing the rubbish This disaster has shown the public the advisability of having a physician for coroner The jury that will hold the inquest upon the unfortunates, is composed of representative business men

The Wayne County Medical Society held its regular meeting on Thursday, November 7 at Dr J E Clark's office Dr Wm A Hackett read a paper entitled, " Points of Diagnosis in Skin Disease "

The Detroit Medical Library Association had a paper by Dr E S Sherrill, entitled, " The Tests and Chemic Significance of Albuminuria "

The Medical Colleges have opened with an increased number of students , the Detroit College of Medicine having 275 in its medical department, 69 in the dental, and 34 in the pharmacy, and the veterinary coming last in number with 10 The Michigan College of Medicine and Surgery has enrolled in its senior class forty-one, junior twenty-five and freshman twenty The pharmaceutic department to this school has been abolished this year

St Louis Notes

The Mortuary Reports for the week ending November 9 give deaths, 167, preceding week, 218, corresponding week of 1894, 153 , death rate, 15 5 per 1,000 Deaths under 1 year, 24 , under 5 years, 41 , over 60 years, 36 Births reported 167

Contagious Diseases reported during the week ending November 9 diphtheria, cases 136 , deaths, 15 croup, cases 12, deaths 4 , scarlatina, cases 9 , typhoid, cases 5, deaths 1 , measles, cases 12 , cerebro-spinal fever, 1 case, 1 death , whooping cough 1 case, 1 death

The St Louis Medical Society — At the meeting of November 9 the scientific program was made up of an exposition of the methods of producing diphtheria antitoxin by Dr Ravold, bacteriologist of the City Board of Health, and a general discussion of the effects of antitoxin in the treatment of diphtheria Dr Ravold explained the method used by the Departments, emphasizing the care taken in every step of the process, and especially the necessity for a painstaking selection of horses and proper care of them during their treatment with the toxin He stated that the Board was now in a position to furnish a considerable amount of antitoxin of a definite strength The dose of this product advised was 20 cc Upon application the Board furnishes the antitoxin free for use in cases that have been properly diagnosticated, requiring only that a careful history of the case and the result of treatment be reported on blanks furnished for that purpose The cases thus far treated had been too few to warrant any report but the results had been entirely favorable The Board of Health was anxious to meet every requirement in this service and invited criticism that the service might be made as highly efficient as possible The speaker was most cordially congratulated on the work done, and the favorable reception given his paper showed how generally the new treatment has won its way into the favor of the profession The general discussion was of special interest from the fact that it brought out no unfavorable experiences All those who had used the antitoxin spoke of its effects in the most enthusiastic praise Dr Langan, who is using it daily, has not yet had a death from diphtheria since he began to administer it, and no unfavorable complications attributable to the antitoxin He uses the remedy to the exclusion of all others, so that his results are to be attributed to the effect of antitoxin alone

The question of erythema and dermatitis with desquamation as occasional effects of the serum was raised by Dr Grindon In the experience of those who had used the antitoxin such phenomena had been but seldom developed and in no case had they been of serious import The complication was in the opinion of Dr Ravold, attributable to peculiarities of the serum other than that upon which its antitoxic power depended, for the serum of some horses produced erythema etc while that of others was without such effects The preservatives used carbolic acid and trikresol were not without objection on this score, as well as on the score of their reduction of the immunizing value of the serum, and he had abandoned these stronger preservatives for camphor which was sufficiently antiseptic for the short period elapsing between the production and application of the serum supplied by the Board of Health He emphasized the necessity of waiting for two or three weeks after the last immunizing dose of the toxin had been administered to the horse before drawing the blood for the separation of the serum, and pointed out how this precaution was apt to be neglected where commercial features attended the production of the antitoxin

THE AESCULAPIAN SOCIETY —Under the auspices of this society Dr Arthur E Mink, of the St Louis College of Physicians and Surgeons gave a lecture at the college November 9 on 'The Psychology and Philosophy of Shakespeare'

THE WABASH SURGEONS —The annual meeting took place in the Southern Hotel, Nov 12 1895 The scientific program included the following papers Delayed and Non union of Fractures by Dr J A Wentz Montpelier, Ohio, Responsibility for Railroad Accidents, by Dr George R Highsmith, Carrollton Mo Hemorrhagic Diathesis, its Relation to Injuries by Dr M Puckett Glasgow, Mo, How to Treat Wounds of the Face by Dr W J Taylor Martinsburg, Mo Two Cases of Open Wounds of the Ankle Joints, by Dr I W Young, Bloomfield, Iowa Fracture of the Vertebrae Dr Burres, Sidney Ill, Fracture of the Femur, by Dr Beardsley, Lafayette Ind, Traumatic Insanity, by Dr James A Duncan, Toledo Ohio, Injury of Cranium and Contents by Dr Jared Spooner, Peru Ind Diseases and Injuries of the Eye peculiar to Railroad Employes by Dr A F Pence Springfield, Ill, The Treatment of Typhoid Fever, by Dr Ben S Lincoln, Missouri City Mo, Intestinal Obstruction Necessitating Laparotomy by Dr Joseph Payne, Edwardsville, Ill, Color Blindness, Methods of Detecting It by Dr I L Henderson, St Louis, Trephining the Spine in Cases of Fracture of the Vertebrae by Dr C B Stemen, Fort Wayne, Cranial and Intracranial Injuries, by Dr W H Meyers, Fort Wayne

A NEW CITY HOSPITAL —The old City Hospital is notoriously unfitted for its purpose, beside inadequate in accommodations, and the Board of Health is discussing a project for the erection of a new building that shall meet all modern requirements

A NEW MEDICAL JOURNAL —*The Specialist* is the name of a new medical journal that is to make its first appearance this month The publication office is at 2012 Washington Avenue The journal will be devoted to diseases of the eye, ear, nose and throat, and is intended to occupy a middle ground between the journal of general medicine and the purely special journal The name does not fairly convey this notion of its proposed function

THE PRACTICE OF MEDICINE WITHOUT A LICENSE —A certain Mrs Billenkamp attended and treated a child afflicted with diphtheria, claiming to have a remedy that would cure the disease The child died and the coroner's inquest resulted in holding Mrs Billenkamp responsible for the child's death She was prosecuted on a charge of practicing medicine without a license The judge discharged the prisoner on the ground that she had not appended the letters M D, to her name and therefore did not represent herself to be a physician This decision has been given here in similar cases and it points out the loophole for the escape of all unlawful practitioners The quack has only to advertise his ability to cure disease, being careful to avoid the use of M D It would be interesting to know whether the use of the abbreviation Dr would be considered as of general or special significance in such a case, whether its general sense might not be used as a defense for its use by any one for a special purpose The law should be framed to cover the spirit as well as the "letter" of the unqualified practitioner

Louisville Notes

DAMAGE SUITS —The profession of this city is much gratified at the result of two suits for damages brought against two surgeons for alleged malpractice In the Common Pleas division one Jno M Reager, sued Dr W O Roberts for $20,000, the plaintiff maintaining that unskillful treatment was received at the hands of Dr Roberts who treated him for a fracture sustained while at work for the railroad Judge Field declared it a non suit, and the case was thrown out of court Clara L Beadle brought suit against Dr L S McMurtry, for, $5 000, alleging that he had placed her under the care of an incompetent nurse, who allowed her leg to be burned by a hot water bottle The jury awarded Dr McMurtry a counter claim of $500 for services rendered the patient There was quite a little tilt between one of the witnesses for the defense, a prominent surgeon, and the lawyer for the plaintiff When asked why, the answer was made that a fee for such an operation could range from $500 to $5 000, the witness replied that he thought $5 000 not an exorbitant charge to one who could afford to pay,—and in the custom of large fees, the lawyers set the pace, and the surgeons followed suit The witness was dismissed and the sum asked for, awarded by the jury

PRACTITIONERS CLUB —At a meeting of this society, held November 13, Dr Gavin Fulton read a paper upon "Leucorrhea"

THE PUBLIC SERVICES

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending November 9, 1895

P A Surgeon L W Curtis, ordered to duty at the Indian Head Proving Ground

P A Surgeon James Stoughton detached from the Puget Sound Naval Station and ordered to duty at the naval hospital, Yokohama, Japan

P A Surgeon C F Stokes detached from the naval hospital at Yokohama ordered home and granted two months leave

Asst Surgeon H D Wilson detached from duty at the Indian Head Proving Ground, and ordered to duty at the naval hospital, Chelsea, Mass

Asst Surgeon C D Brownell, ordered to duty at Puget Sound Naval Station, on completion of his examination for promotion

American Medical Association

VOL XXV CHICAGO, NOVEMBER 23, 1895 No 21

ADDRESSES

CHAIRMAN'S ADDRESS

Delivered before the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY DANIEL R BROWER, M D
CHICAGO

Gentlemen —Through the indefatigable exertions of our distinguished Secretary, we have before us the best program ever presented to the Section

An effort has been made to arrange the work along three importent neurologic lines, and you will have presented to you papers on these several topics from some of the most eminent physicians of the country, and I trust that we will be equally favored in the learned discussions that will follow

As you observe, the first symposium is on hypnotism, a subject now very prominently before both the profession and the laity, and they earnestly desire that some such representative body as this, will make positive declarations as to its value in the cure of disease and as to its place in criminal jurisprudence The papers that will be read and the discussion that I trust will follow, will at least bring us *nearer* to a settlement of these important questions

The symposium on electricity is timely This force so prominently before everybody, and because of its varied and almost universal use, demands our careful consideration in order that we may assist, at least, in determining its true place in medicine The work of this Section will, I trust, not only aid in this important solution, but will develop new mechanical appliances to facilitate the use of the energy and new methods of application that may yield better results in treatment

The last symposium has for its subject epilepsy As you are well aware, this disease known from the very earliest times, accurately described by the most ancient writers, is still the *bete noir* of the profession Only about 7 per cent of the cases are cured, and about one in every five hundred of the population is so afflicted May we not hope that the papers and discussions that will emanate from this great array of talent may improve this record of curability and diminish this percentage of prevalence?

It is hardly necessary for me to take your time to review the work that has been done in the field covered by this Section during the past year Every person here present is as familiar with this as I am, but there are certain things in the line of progress with which you may not be so familiar In the State of Illinois we are about to try the experiment of an industrial epileptic colony, modeled somewhat after the Craig colony of New York and the famous Bielfeld colony in Germany It is proposed to begin this colony with the epileptics, about eight hundred in all, now in the county almshouses and other public institutions This colony may in part aid in the more successful treatment, as well as diminish the large proportion of these unfortunates now existing

In Illinois we are also trying to improve the quality of medical expert testimony Some recent trials in which much of the medical expert testimony was very discreditable, have aroused the profession to such a degree that the six prominent medical societies of Chicago met by their joint committee and drafted a bill that has been indorsed by all of these several societies, by the State medical society and several of the county and district societies, that may elevate the tone of this most important service It is as follows

A draft of a Bill for an Act authorizing the judges of criminal jurisdiction in the State of Illinois to appoint persons to act as expert witnesses

Be it enacted, By the People of the State of Illinois in the General Assembly represented, That the judges of the circuit and superior courts of the State of Illinois, be and the same are hereby authorized to appoint in the month of January of each year, persons who shall act as expert witnesses in the medical and other sciences in giving opinion upon the evidence, as presented in a hypothetical form, of criminal causes that may be on hearing in the courts presided over by the said judges Such expert witnesses shall hold their said appointments for one year or until their successors are *appointed and qualified They shall be entered as expert* witnesses upon a list of such witnesses kept by the circuit clerk, and the said clerk shall issue a certificate of appointment as such expert witness to the person appointed as above

Such expert witnesses shall be citizens of the State of Illinois and shall be known in the communities where they reside for their professional competency and personal probity, and if physicians they shall have been at least five years in lawful and active practice When expert opinion is desired in any cause pending in a criminal court, the trial judge presiding in such cause may, at his discretion summon for duty under this Act, such expert witnesses to the number of three Such expert witnesses shall be paid for their services by the county in which the trial for which they are summoned is held, in such sums as may be named by the judge

It shall be the duty of such expert witnesses to give an opinion on the evidence as presented in hypothetical form in the case in which they are called Such experts shall be subject to cross examination by both prosecution and defense , but such cross examinations shall be limited entirely to the subjects embraced in their opinion

In criminal cases previous to trial, if the State's Attorney deems it advisable to have expert opinion, he shall so state to the court having jurisdiction of the cause and the judge receiving such statement may summon expert witnesses to serve under this Act

This Act has been amended as follows

A BILL

[HOUSE BILL No 767]

For an Act to regulate the taking of expert testimony in civil and criminal proceedings

SECTION 1 —*Be it enacted by the People of the State of Illinois represented in the General Assembly*, That in any case on trial in a court of record in this State where expert testimony is to be introduced by both the prosecution and the defense and also in any other case in the discretion of the court the presiding judge shall, either of his own motion, or at the request of either party to the suit subpœna one or more persons who shall be known as court witnesses

SEC 2 —Such court witnesses shall be citizens of the State of known personal probity, and only such as are recognized in the communities where they reside as having special knowledge and experience pertaining to the subjects upon which they are to testify; and if physicians, they shall have been not less than five years in lawful and active practice

Sec 3—The presiding court shall fix the fees of such court witness or witnesses, but in no case shall the fees allowed such court witness exceed fifty ($50) dollars per day Such witnesses shall be paid in the manner provided by law for other witnesses, except that in criminal cases the fees of such witnesses shall be paid by the county

In this amended form, the bill will probably become a law

In closing, I can not refrain from making mention of the important studies that have been made on the influence of infectious processes on the nervous system. Drs Mills, Putnam, Dercum and others have shed a flood of light upon this important subject, and suggest methods of relief that may lead to valuable results

I must also mention the studies on the use of the thyroid gland in the treatment of sporadic cretinism by Drs Telford Smith, Byran Bramwell and others that seem to offer some relief to these imbeciles, and teach us relations of the thyroid gland to general nutrition never before known

---

RESPONSE TO THE TOAST, "EPHRAIM McDOWELL"

Delivered at Annual Banquet of the Chicago Gynecological Society[1] Oct 18, 1901

BY JOSEPH EASTMAN, M D

INDIANAPOLIS

In a hallowed spot, a typical American home, in Rockbridge Co, Va, Nov 11, 1771, a male child was born It has been said that "great men, like great mountains, stand alone, with the valley of ancestry on the one side and the gulf of posterity on the other' This towering character, however, did not stand alone, for the foot-hills of his ancestry were of decided magnitude, prophetic of a genius destined to become one of the greatest benefactors of the human race His ancestry for three generations commingled the best Scotch and Irish blood, coursing the arteries of men and women of strong bodies and strong characters—characters emphasized, energized and vitalized on historic battle-fields with red-skins, red-coats, wild beasts and hardships of the primitive Virginia forests

Figuratively speaking, this child was number nine in a family of eleven children When 13 years of age his parents moved to Danville, Ky, a long, tedious and even perilous journey, a journey in itself well calculated to develop and toughen the fibers in our valiant hero

At Danville he grew up to full physical manhood, tall, well proportioned, beautiful What a wonderful advantage it is to grow up in the country, to commune with nature, to enjoy the beauties of green fields instead of paved streets, to gaze on great oaks and elms instead of steeples and chimneys, to see the radiant tints of the morning dawn and the beauties of the setting sun, where the mind can grow commensurate with a healthy body, where one can develop and cultivate the greatest of faculties—that of thinking, without having the continuity of thought interrupted by the rattling of electric cars, the rumbling of omnibuses or the shrieking whistle of steam engines, where one can see in reality what art galleries only imitate, and while enraptured with the works of nature and the created, become filled with the realization of the existence of a Creator And then, too, to be reared under the influence of such parents as our hero had The lasting impressions of our lives are received beneath the cloudless sky of childhood, while our guiding star is the approving twinkle of the paternal eye, the chief luminary of our pathway the vitalizing sunshine of a mother's countenance, and every footstep guided by the subduing influence of a mother's love

After obtaining his literary education at Georgetown, Ky he went as a student of medicine to Dr. Humphries, in Stanton, Va History tells us little of this Dr Humphries except that he was educated at the University of Edinburgh, but surely he, too, was a man of great intellectual endowment Dr. Samuel Brown, of Kentucky, and Dr Hosack, of New York, were also his pupils and arrived at a great distinction as practitioners and teachers of medicine and surgery In 1793–94 our hero attended lectures at the University of Edinburgh Pause for a moment, and think of a young American so ambitious that the entire faculty of this great university could not satiate his thirst for knowledge, for going outside he employed Dr John Bell, a great character, so enraptured in teaching anatomy and surgery that he filled his pupils to overflowing with professional zeal. In 1795 our hero returned to America and began the practice of medicine at Danville, Ky, where he soon had a large clientage, often riding 50 and 100 miles on horseback He faced dangers from storm and flood, in clouds and darkness at night, at times becoming lost in the dense forest He was actuated by the higher principles of his profession, he feared neither man nor devil, he knew no fear except the fear of doing wrong The degree of his happiness was determined by the magnitude of his undertaking.

On Dec 13, 1809, he was called to see a Mrs Crawford whose attending physician had thought her pregnant, although he knew she had gone beyond the usual time Dr Eastman being a thorough master of all that was known of that highest department of our art, namely, diagnosis, declared that she had an ovarian tumor and at once suggested its removal Had he deceived her by an untruth, or kept back from her the whole truth, she would have known it, would have read it in his countenance, and would not have replied "Doctor, I am willing and ready" But he stated to her that so far as he knew the operation had never been done—that it would be an experiment, therefore he could make no promise as to the outcome He thus unlocked the bosom of confidence with the key of personal magnetism By his manly presence and honest words, he planted a new hope in the heart of despair This woman made the journey sixty miles on horseback on a bleak December day in compliance with the wisdom of this great and good man, that she might be near him so that in a critical moment he could with his own hand ward off the approaching danger When it became known what he was about to undertake, he found a mob was gathering about his house He learned that if the patient recovered it would be well with him, but if she died from the operation he was to be at the mercy of a merciless mob He offered up a prayer and proceeded with his task This prayer in fervency and literary merit has rarely been equaled Permit me to remark, greater heroism was never displayed by man or woman Martyrs burned at the stake could not escape the death if they would This personification and crystallization of heroism could not abandon his principles, and escape the danger if he would More than that, genuine heroism must be delicate, must be premeditated, must be actuated by a pure a high, a holy and beneficent motive It was not a maddening pseudo heroism stirred up by the rattle of drum and shriek of fife on battle fields, where man seeks to slay his fellow-man.

---

[1] Delivered without manuscript

I insist that the heroism of Napoleon or Grant can never be compared to that of this cool, calculating, thinking man I repeat the heroism that seeks to destroy human lives is incomparable with that which seeks to save a human life and establish principles which shall not only save one life, but which shall continue to save human lives throughout all coming ages The operation was completed, and during nearly a century has not been improved upon, his technique was almost identical with what we have to day The substitution of a gauze for the drainage tube still more nearly approaches the ligatures which he allowed to hang out the lower angle of the wound—the best of capillary drainage Mrs Crawford lived thirty years Our hero made the operation thirteen times with eight recoveries, and at 60 years of age returned from visiting a patient, laid down his instruments for the last time and secured that rest which he never could enjoy while a call to the bedside of a suffering patient was pending Surely such a life of unselfish devotion to the cause of humanity would make him a fit companion for the gods

"To such a life there is no death,
What seems so is transition
His life, his mortal breath,
Was but a suburb of the life elysian
Whose portals we call death"

He was an honest man, honest to his patients, honest to his God, and therefore honest to himself He was a great man with a large head, a large capacity for thinking, and a large, a true and a loving heart—essential qualifications for a great surgeon

He was a wise man With inborn wisdom he accumulated and applied knowledge He was a brave man No truer heroism has or ever will be recorded on the immortal pages of never ending history He was a humane man He owned slaves, occasionally bought one to unite families—but never sold one He did not approve of traffic in human blood

He was a handsome man

'Beautiful eyes are those that show,
Like crystal panes where heart-fires glow,
Beautiful thoughts that dwell below
Beautiful lips are those whose words
Spring from the heart like songs of birds—
And yet whose utterance prudence girds
Beautiful hands are those that do
Work that is noble and brave and true
Moment by moment the long day through"

His was a beautiful life

'Beautiful lives are those that bless,
Some silent river of happiness
Whose secret fountains few can guess"

Virginia is justly proud of her statesmen, of her orators and her soldiers, "but shall not the achievements of her statesmen succumb, at last, to the pitiless logic of events? Shall not the voice of her orators grow fainter with coming ages? Shall not the victories of her soldiers be found at last only in the libraries of students of military campaigns, while the fame of this village surgeon, like the ever-widening waves of the inviolate sea, shall be wafted to the utmost shores of time, hailed alike by all nations in all ages for having lessened the burden and prolonged the span of human life" A thousand years hence, if a student of medicine shall ask who first did ovariotomy the answer will be prompt and unequivocal As a result of this self-sacrificing life and marvelous achievements there goes forth a benediction to every home in the civilized world, from every hearthstone in Christendom there returns a blessing to the memory and the resting place of Ephraim McDowell All honor to this honest, great, wise, heroic, good, kind, gracious, loving and lovable man!

ORIGINAL ARTICLES

A CASE OF CONGENITAL MUCOUS POLYPUS OF THE NOSE—WITH REMARKS

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md, May 7-10, 1895

BY DUNBAR ROY, M D

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN SOUTHERN MEDICAL COLLEGE, ATLANTA GA

It is not my intention in this short article to go into the minute discussion of that pathologic condition known as mucous polypi of the nasal cavities, nor to adduce any new and original method for their eradication which has not already been brought before the profession at large, but with a few prefatory remarks I wish to report the history of a case of congenital nasal mucous polypus which is of sufficient rarity to render its report not entirely inappropriate for this Section The subject of nasal polypi is an old one and perhaps the first morbid condition of these cavities which was undertaken to be rectified by the surgeon and physician alike, since its presence was perhaps the easiest recognized of all diseased states of the nasal cavities Our medical periodicals and society reports have for the last few years teemed with articles upon the etiology and best method of treating polypi until, at the present date, one wonders that any physician should slip into the error of even mentioning the subject unless he has, by original research, some new light to throw upon certain points as yet disputed The two points which have especially vexed rhinologists and upon which there seems to be the greatest diversity of opinion, are the etiology of these mucous growths or outgrowths and the best and most satisfactory method of treatment

As to the etiology, there is by no means a unanimity of opinion, but, in fact as would naturally be expected, each rhinologist holds his own views upon the subject The only point upon which they all agree is in recognizing this pathologic condition as one of adult or advanced life, and a condition of extreme rarity in the very young To the rhinologist who has had any extended experience in the treatment of nasal polypi and has been a close observer the views of Woakes of London, or at least a modified form of them, must certainly present the clearest and most satisfactory explanation in regard to the etiology M McKenzie admits that the etiology is unknown, while Sajous says that it is due to a chronic inflammation of the Schneiderian membrane But why is it that the same character of inflammation certainly as far as we can observe, produces polypi in one subject and not in another? I, myself, am a strong believer in hereditary predisposition, especially as I have seen this morbid condition in different members of the same family, and every rhinologist is familiar with the characteristic nasal expression in patients afflicted with nasal polypi, which is by no means always a *propter hoc*

Nor are all writers agreed as to what is the usual condition of the mucous membrane lining the affected side, since some hold that it is always hypertrophied while yet others that atrophy exists

Woakes' theory of explanation as I understand it, is this that long standing chronic catarrh of the hypertrophic variety causes the middle turbinate to return to its embryonic condition, that is, it becomes cleft in two portions running antero posteriorly Between this cleft, the blood supply not being sufficient, true mucous membrane is not formed, but in its stead a myxomatous structure accumulates, which by gradual enlargement increases the space thus formed and which in its final development is a true mucous polypus These views of Woakes upon "necrosing ethmoiditis" a most unfortunate term, have been severely criticised by some throughout the medical world, and especially has it been done in London by Walsham, Hill and Lennox Browne, a full discussion of which was published in the *Journal of Laryngology* of August, 1891 As every one knows, Browne has long antagonized these views and his ideas upon the subject are, according to him, in accord with the majority of rhinologists, believing that when such a condition of affairs exists as Woakes describes, it is accidental rather than universal He contends that in such cases the evidences of this necrosing condition are absent, both histologically and clinically, viz absence of odor, the sequestra of necrosed bone and other pathognomonic symptoms Woakes, on the other hand, replies that he did not mean that necrosis was present in every case, but that the pathologic condition was such as to lead to it were the parts not radically treated Whether we agree fully with these views or not, I believe every rhinologist must admit the importance played by degenerative changes in the ethmoid, especially the middle turbinate, in the production of polypi, chronic discharges, etc

Dr W E Casselberry of Chicago, in a paper read before the American Laryngological Association in May last, has discussed the question of etiology and treatment in a most admirable manner, and has instituted a classification which accords entirely with my own clinical views It is a paper well worthy of preservation and one that should be in the hands of every rhinologist

While nasal polypi in the adult is a common occurrence and their pathology has been minutely studied, the same condition in children is extremely rare, and therefore by no means so clearly understood M McKenzie, with even his large experience, is reported to have said that he never saw but one case in a subject under 16 years of age The rarity of these cases has been the ground for their being reported in the medical literature S Hopmann of Paris, has reported that he found nasal polypi in 8 children out of a total of 246 such cases operated upon Natier, in the *Annales de la Polyclinique* of July, 1891, has published an elaborate study of mucous polypi in children up to the age of 15 He compares the general opinion as to the extreme rarity of these growths during the first years of life with that of Hopmann who considers them sufficiently frequent before the fifteenth year to represent a proportion of 7 per cent Natier was not able to find a single instance in 1,200 cases of nasal trouble carefully examined at his clinic, including a large number of children as patients, while, at his request, a close examination of the records of Moure's clinic recorded only 5 cases of mucous polypi in children among 10,520 cases He therefore concludes that Hopmann must have met with a series of cases as a coincidence, or that the climate of the region in which he lives is particularly favorable to the growth of these neoplasms The same author, in the *Paris Medicale* of February, 1892, reports a case of congenital mucous polypus, and in looking up the literature he has found of congenital polypi, in addition to his own, three cases of polypi in children under 5 years of age, ten cases in children between the ages of 5 and 10 years, and sixteen between the ages of 10 and 15 LeRoy of Paris, has reported a case of congenital polypus by finding that an infant had much difficulty in taking the breast, and on examination a polypus was found in the left nasal fossa Cases of polypi removed from children under the age of 7, have been reported by P Heymann and Michael of Hamburg

From these few prefatory remarks, one may judge of the rarity of such cases of congenital polypi, and of those occurring in children under the age of 15 I believe, however, that if a thorough examination was made in cases of children suffering with a chronic discharge from, or an obstruction in, the nasal cavities there would be a greater number of such cases reported than has heretofore been the case

The case to which I now wish to call your attention presented some striking features in the cavity from which the growth was removed, and which I shall speak of in detailing the history

In one of my routine visits to the Home for the Friendless, the matron brought in a young girl 14 years of age, who complained of her inability to breathe through the left side of the nose On inquiry the following history was elicited

Her father was living, but mother dead According to patient's statement she has never been able to breathe through the left side of her nose At the age of 5 she was chloroformed three times when growths were removed from the left side of the nose, and in the last six years she has been operated on three times, having had large pieces removed at each sitting—with the result, however, of never affording her breathing space on that side At present she says her nose feels about as well as it ever did She complains of marked asthenopia and photophobia of the eyes Is unable to read for any length of time. Suffers with headaches Otherwise the patient is well nourished and is of a large and healthy frame

Upon examination, I found one immense mucous polypus which filled the whole left nasal cavity, from the anterior meatus back into the post-nasal space With a Jarvis snare, I removed what I thought a good portion of the growth, but to my surprise on again inspecting the parts, no impression seemed to have been made upon its size As my surroundings for operating were very unsatisfactory, I instructed the matron to bring the young girl to my office In two weeks time I operated again, removing two pieces about the size of the first, and on my third attempt succeeded in invaginating the greater portion of the polyp with the wire loop, and in this manner finally removed the growth *in toto* Strange to say, there was no bleeding whatever, and on inspecting the cavity I found the following conditions the mucous membrane was atrophic throughout, and there appeared nothing but a large, open, glistening cavity The inferior turbinate was scarcely discernible as such, while the middle turbinate showed but the slightest rudimentary shelf The whole outer wall of the cavity showed one large depression in which the polypus had evidently lain The septum at its lower portion was perfectly straight while the upper part of it was very much deflected toward the right, showing the evidences of mechanical pressure No secretion whatever was present High up beneath the rudimentary portion of the middle turbinate, the growth had its origin from a space not over one-quarter of an inch in length No distinct cleaving of the turbinate was recognizable The point of origin could be thoroughly cauterized so that I fear no prospects of a return, as now evidenced after several months

From the history of the case and the changes found in the nasal cavity after the removal of the growth, there is no doubt as to its being congenital in origin The important features about the case were the destructive changes which it produced through pressure upon both sides of the cavity The right side showed no marked pathologic changes save a distinct hypertrophy of the inferior turbinate, which was so much in contrast to the atrophy existing in the left nasal cavity

Dr Jarvis in the *Journal of Respiratory Organs*, April, 1890, in an article upon nasal polypi, insists upon the importance of the superior deflection of the septum as a cause for the growth of polypi and the necessity for its correction in order to effect a cure He, therefore, explains the etiology of congenital and hereditary cases by attributing them as due to this herditary septum

Cordone of Italy, has reported a case of congenital polypus where he found the same superior deflection of the septum as referred to by Jarvis, and which thus supports the views of the latter

In my own case this deflection was a very noticeable feature, whether it was one of the causes or only a result of the polypus I am unable to say, but my firm opinion is that it was the latter, since in the point of origin I could see no relationship between the two

In regard to the treatment of polypi I have nothing new to offer, only that I wish to add my testimony to the success of a treatment recommended by Dr E H Griffin of New York, and that is the spraying of the affected nasal cavity every night and morning for a year with either hamamelis or pure alcohol Since the majority of polypi spring from the sulcus, up and behind the middle turbinate, I have found it best to saturate a piece of cotton with pure alcohol, pack it firmly in the sulcus and allow it to remain for half an hour at the time Such mild and prolonged treatment may be criticised by my more radical colleagues, but in many patients who are so averse to any operative measures in their nasal cavities, I have found this mode of procedure of inestimable value

DISCUSSION

Dr Price Brown, Toronto—Has only seen one case of congenital nasal polypus This occurred in a child aged 2½ years The polypus was pedunculated and presented in the naso-pharynx, being visible orally Under chloroform I removed it digitally, scratching off the polypus from this vault by the finger nail

Dr S K Merrick, Baltimore—Touching the question of congenital polypi, I have never seen a case which I knew to be congenital, but I have had at least two cases under 2 years of age, when a history of obstruction had existed from birth, or shortly after, and I am willing to accept as an established fact that we do have congenital polypi As to the etiology, I believe in many cases imperfect drainage, due to deflection or spurs of the septum is a contributing cause, and as to the question of site of origin being invariably from the turbinates, I am prepared to disprove I have a specimen removed from the nose of a man 48 years old, where a large spur, having a large mucous polyp attached, is suspended in alcohol, showing the polypus growing from that portion of the septum

Dr Casselberry—Some years ago I reported the occurrence of a nasal polypus in a girl aged 9 years who had been previously affected for several years It must have originated at a very early age, although I do not think it was congenital At that time I expressed an opinion that nasal polypus in young children was not so rare as had been generally supposed Concerning the etiology, Dr Jonathan Wright concludes from microscopic studies that they are inflammatory growths occurring in the course of chronic rhinitis, although why the minority only of cases of chronic rhinitis should suffer from this complication and the majority escape, is not yet known I have elsewhere pointed out that deflection or excrescence of the septum or other conditions which cause unusual narrowing or stenosis of the nostrils by impairing the natural drainage and causing the accumulation of decomposing muco-purulent material might influence the transformation of the ordinary hypertrophic rhinitis into the myxomatous type All degrees of this transformation are observed clinically, especially on the middle turbinal from that which is best described as a polypoid degeneration of the hypertrophied turbinal to the typical pedunculated polypus which may occasionally be found attached to the middle turbinal itself The more common point of attachment for polypus, however, is in the middle meatus, high up beneath the middle turbinal, growing from and projecting through the hiatus semilunaris from the immediate vicinity of the ethmoid cells, and in these cases the underlying condition or cause is an ethmoiditis, not necessarily of a 'necrosing" type, but that which is better termed a myxomatous ethmoiditis

The treatment should consist of as thorough extirpation as possible by the cold wire snare, followed by curetting of the base The galvano-cautery experience has been shown to be objectionable, on account of the liability to the formation of adhesions when insinuated into crevices In certain obstinate cases, in order to gain access to the seat of attachment in the middle meatus, I have resected the anterior end of the middle turbinal

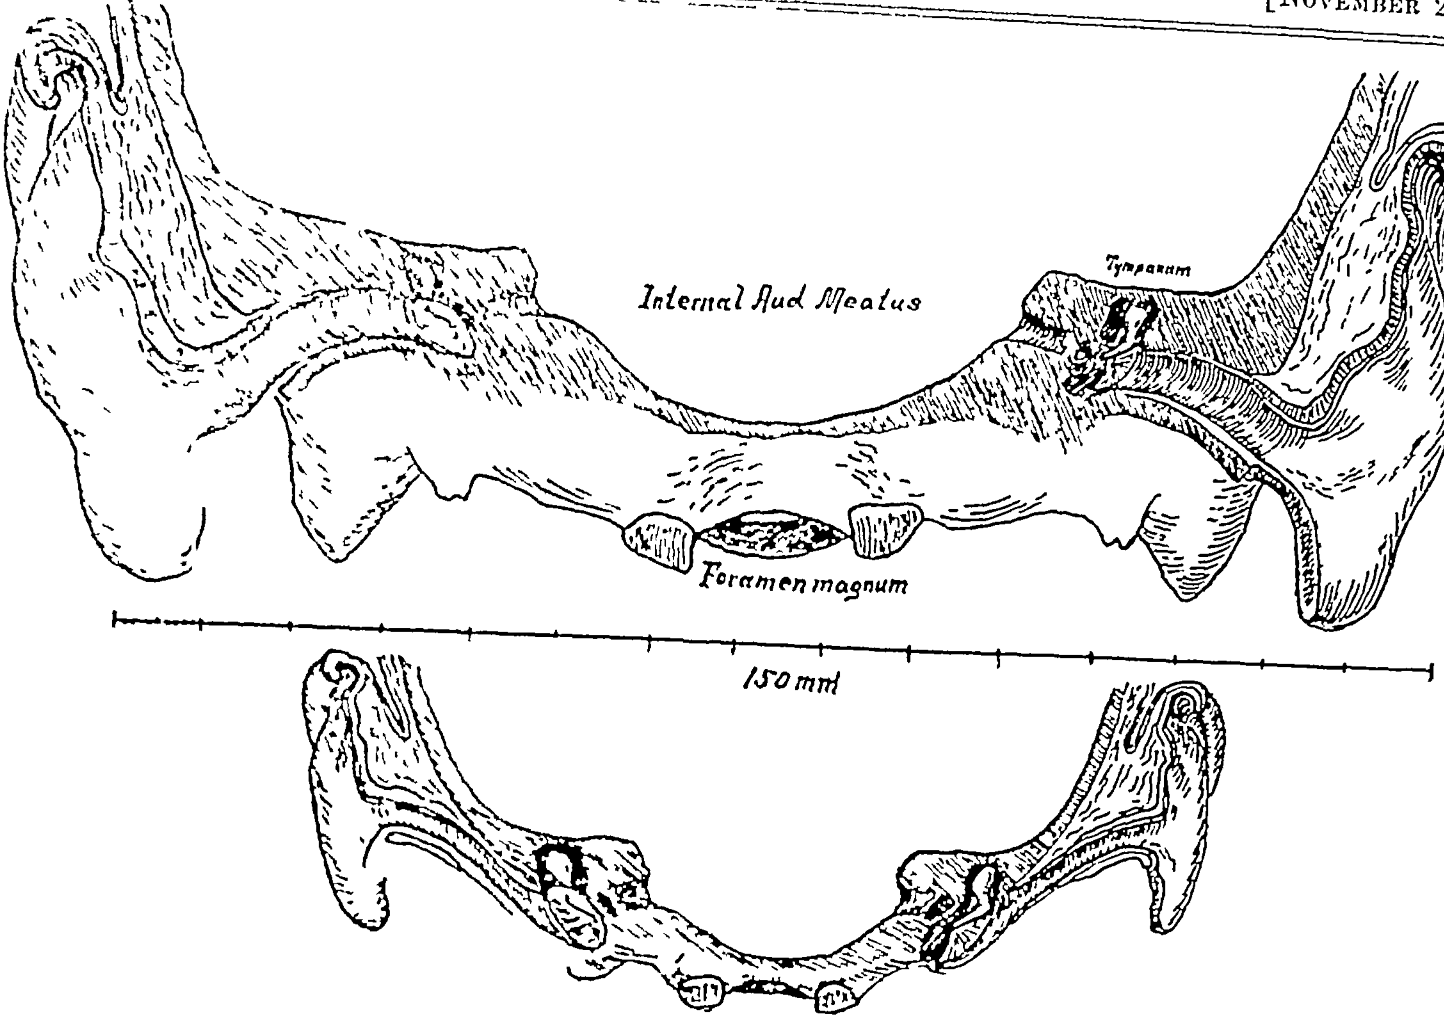
THE IMPORTANCE OF AURAL ANATOMY IN ROUTINE CLINICAL WORK

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association held at Baltimore Md May 7 10 1895

BY B ALEX RANDALL, M A, M D
PHILADELPHIA

That the aural surgeon must have the topography of the ear and the surroundings clear in his mind and ready at his finger ends, when operating on the mastoid or still more within the tympanum, is evident to all He must be thus posted, or wholly belie his status as a specialist Yet it is no less true that the practitioner who would well treat, topically, the routine cases, still more attempt paracentesis as most of the text-books advise, must know the variations in the configuration of the external auditory canal, the size, depth and inclination of the drum-head and the structures which lie beyond it within easy reach of damage by his manipulations Unfortunately, much experience in post-graduate teaching shows that the majority of men of some otologic experience reveal serious defects in this direction, and do some very bungling work, however posted in the theory not so much from inexpertness, as because of erroneous anatomic impressions

For this, many text-books of surgery, anatomy and even of otology are distinctly at fault Misstate-

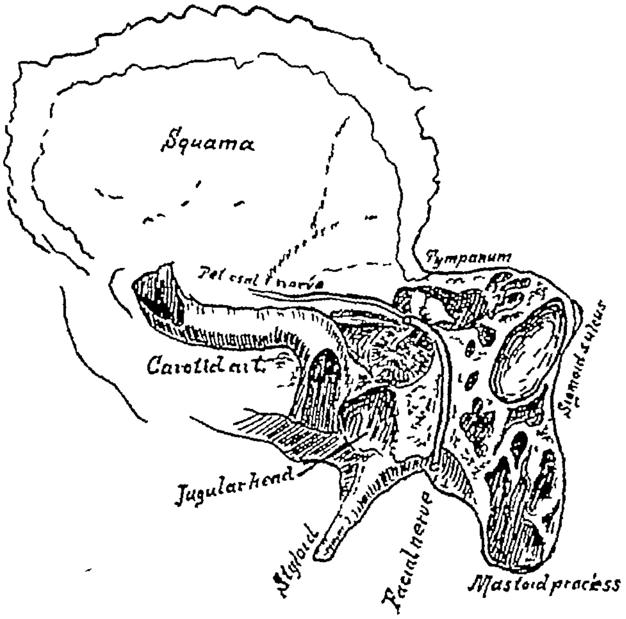


ments abound and pass current without the brief examination needed to correct them Hard and fast statements are made as to the most variable points, alternating with vague and inadequate data on matters calling for more explicit description Few even of the aural treatises deal adequately with the external meatus in its individual variations and its development from the infant to the adult form I find a common misapprehension, that because the drum-head of the infant is on the plane of the skull surface the auditory canal must be shallow The astonishment with which physicians see a probe passed in an inch and a quarter, before touching the tympanic membrane of an infant is almost universal The usual text-book statement that the drum-head is much more horizontal in infant life than later, is accepted, of course, and every demonstration of an identical position with that of the adult is generally looked on as an exception and anomaly That the drum-head, ossicles and labyrinth are full sized before birth, surpasses the credible to most medical men, who naturally support common analogy by text-book misstatements

The variable direction of the auditory canal counts as much as its width and straightness in the question of what should be visible at its bottom, but I know of no statistical measurements in this regard except those brought by me before the American Otological Society last year This is of extreme importance to the operator, but it greatly concerns every practitioner who undertakes to cleanse an ear Supposing a bulging inflamed drum-head offers itself with exceptional clearness to the view of the practitioner and demands incision, how few are acquainted with what lies within it, all too easily damaged by anything but the most precise operation The inclination of the drum-head to the axis of the canal is generally fairly stated in the books, yet few practitioners adequately appreciate how much farther from the surface the anterior part of the membrane is than the upper posterior In the narrow canal, little use can be made of parallax in estimating the distance of points, so one must generally depend on his anatomic knowledge of the position of known structures and, as to the unknown, make tentative use of the probe

The great importance of this combined employment of sight and touch in learning practical aural anatomy, inclines me to strongly advocate the use of the cotton carrier in cleansing, since it may be as gentle as any other means, while far more instructive and, at times, more efficient By such practice the beginner can speedily learn the relations and obtain a delicate confident touch, which will serve him equally in successful routine work and in the most intricate operative procedures Bearing these drum-head details in mind, incision of the drum-head can doubtless be safely done by any one of fair skill, unless he undertakes it as a stab of the chosen point, because so taught or from the unsteadiness of the patient Then he always endangers the structures beyond—the stapes, chorda and possibly the facial nerve, if operating up and back, the mucous membrane of the promontory below and the head of the jugular in the floor of the tympanum The reported cases where the jugular has been thus opened are probably far fewer than the occurrences of the accident, for it must not be forgotten that the thinnest of bone, often dehiscent, alone intervenes As to the facial nerve, its bony canal is not infrequently incomplete just above and behind the oval window, and aside from injury as the result of operation or even of mere probing or cleansing with cotton, this anatomic condition should not be forgotten in its rela tion to Bell s palsy That authority to the contrary notwithstanding, I am sure that the large majority of cases of acute facial paralysis are due to inflammatory affection of the nerve and its sheath, not at the stylo-mastoid exit, but as it passes through the tympanum The tympanic inflammation is generally transient and sometimes painless, but prompt study will rarely fail to note the evidences of it The bearing of this upon prognosis and treatment is evident

One farther instance may be cited—the anatomy of the Eustachian tube in its relations to the physiology of the ear and the therapeutic matter of inflation Anatomists and physiologists have contended as to whether the tube is normally in a closed condition Section shows its lumen reduced to a mere cleft by contact of the anterior and posterior walls, but Rudinger has pointed out the open "safety tube" above, in the hollow of the hook cartilage Clear as this is in the middle portion of the tube, it is not present throughout its length, and we are normally dependent upon the dilating action of the so called palate muscles (of which the outer portion of the tensor palati is at times purely a dilator tubæ) to render it patulous Of this, Politzer has furnished us a nice demonstration which is also a most useful test of the normality of the Eustachian tubes If the sounding tuning-fork is held before the nose, it will be faintly heard until the act of swallowing calls into action the tubal muscles, when it will be momentarily much more audible Without any needless inflation, we can thus at once test not only their physiologic condition, as could be only inferred from their ready penetration by the injected air, but can note even minor differences in the freedom on the two sides Another demonstration of the same normal closure of the tubes will be found in the contrast with the effort to exhaust the tympanum by a suction effort, with the completeness of the success of the Toynbee or negative Valsalva procedure, of swallowing with the nose closed



Dear Doctor —Please direct the attention of your friends to *our* JOURNAL We will be pleased to send sample copies to any names you may suggest

RECURRING OR HABITUAL EPISTAXIS, WITH A CONSIDERATION OF THIRTY-SEVEN CASES

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10 1895

BY E L VANSANT, M D

ADJUNCT PROFESSOR OF DISEASES OF THE THROAT AND NOSE PHILADELPHIA POLYCLINIC SURGEON TO THE THROAT, NOSE AND EAR DEPARTMENT OF THE HOWARD HOSPITAL ONE OF THE PHYSICIANS TO THE PHILADELPHIA HOSPITAL PHILADELPHIA

The term recurring or habitual epistaxis designates a class of cases where nasal hemorrhage of varied degrees of severity recurs at intervals, during a greater or less period of time The history given in some of the cases is that of a slight hemorrhage, perhaps only sufficient to lightly stain the handkerchief after blowing or picking the nose Such slight oozing may recur several times daily or at comparatively long intervals In other cases, the history is that of a profuse hemorrhage lasting several minutes or longer, which may occur after blowing the nose, or follow any slight mental or physical excitement The frequency of the attacks may vary considerably

Among the general causes of recurring epistaxis are

1 Diseases affecting the blood vessels or associated with alteration of the constituent parts of the blood as in scorbutus, purpura hemorrhagica, simple and pernicious anemia, plethora, hemophilia, malaria, and exceptionally in septic diseases such as pyemia, septicemia, etc

2 Certain acute diseases, such as typhoid and relapsing fever, and occasionally in pneumonia, diphtheria, etc

3 Diseases producing local or general vascular congestion, such as valvular disease of the heart, pulmonary affection, cirrhosis of the liver, chronic nephritis, amyloid degeneration and mediastinal tumors

4 It may be the expression of a vicarious menstruation, or,

5 May accompany the course of a pregnancy

Among the local causes may be assigned

1 Tumors such as fibroma, carcinoma and sarcoma, particularly angiosarcoma, fibro and myxosarcoma

2 Varicose enlargement of the veins, particularly on the anterior portion of the septum

3 Perforating ulcer of the septum

4 Trauma

5 Local ulcerations caused by syphilis, tuberculosis and lupus, and, finally,

6 Deformity of the septum, associated with erosion or ulceration of the mucous membrane of the septum

The most frequent predisposing cause is some slight deformity of the septum affecting its anterior portion The abnormality may be but a small or moderate sized enchondroma or exostosis, or it may be a slight deflection of the septum, the seat of some former fracture with marked thickening of the convexity

Accumulations of dust and mucus occur on the apex and anterior surfaces of the projecting portion, and as such accumulation is very difficult of removal by blowing the nose, the patient will endeavor to obtain relief by picking it away with the finger or the handkerchief, in so doing slight erosion of the mucous membrane occurs This may excite a slight hemorrhage, which in turn forms a small crust and the process of removal and bleeding is continued In some instances the process goes no further the patient having a slight hemorrhage only when the no-is picked In other cases the ulceration gradually extends deeper into the tissues and the hemorrhages are more profuse, often produced by simply blowing the nose or any mental or physical excitement

The ulcerations are most liable to occur when the deformity of the septum is moderate, whereas in marked deformity, producing great stenosis, the draft of air is so cut off that very little dust is drawn into the obstructed nostril and fewer crusts are formed.

In thirty-seven cases of habitual epistaxis occurring in my practice recently, I found that twenty-eight were due to slight deformity of the anterior portion of the septum as just described, with ulceration of the projecting or convex side of the deformity Three were due to deviation of the septum with ulceration on the depressed or concave side Two were due to ulcerations associated with atrophic rhinitis One was a vicarious menstruation Three occurred in typhoid fever

The severity and duration of the affection in the observed cases varied greatly. The majority of the patients were not aware of any existing nasal obstruction, nor was the deformity sufficient to produce marked stenosis In quite a number, various abnormalities producing catarrhal conditions were present, in addition to the septum deformity

The observation of ulceration of the septum as a cause of epistaxis is by no means a new one Among the articles calling attention to it may be mentioned those by G M Lefferts,[1] B Robinson, Chiari[3] and Baumgarten[4] The more recent text-books also recognize its etiologic importance The presence of slight septal deformity has, however, not been so generally recognized, nor has the importance of correcting such deformity in order to obtain permanent relief been well developed Again, the general profession has not fully appreciated the fact of this being so frequent a cause of bleeding Perhaps the trivial nature of the lesion in some cases, may be the reason that more importance has not been attached to it In a large number of the cases that came under my observation the local lesion had not been previously recognized although they had long been under medical care These cases were supposed to have some latent cardiac or vasomotor affection, but local examination revealed the true source of the hemorrhage

The following cases from my records will illustrate some of these observations

Case 1—Mrs A B, age 30 years, consulted me in January, 1892, with a history of repeated slight nasal hemorrhage She stated that in the left nostril a small scab frequently formed which she could only remove by hard blowing or picking The removal of the scab always caused a slight hemorrhage that lasted but a few minutes This condition had continued for the past four years and was better during the summer and worse during the winter The nose always felt free, except during the cold weather when catarrhal symptoms developed Examination showed a slight deflection to the right of the anterior portion of the septum Upon the apex of the deflection was a small ulcer covered with a crust, upon removing this a slight hemorrhage occurred With the exception of a moderate hypertrophy of the lower turbinated body of the opposite side, the nostrils were fairly normal The ulceration was readily healed by treatment, and the hemorrhage promptly ceased Operation for removal of the slight obstruction was, however, refused About three months later the patient returned with renewed ulceration and hemorrhages She confessed to having recommenced picking the nose A cure was again effected and operation again refused Since then I have had the same experience with her at intervals If this patient could refrain from picking the nose or have the septal projection removed there would be *no further* epistaxis

Case 2—Mr C D, age 19 years, college student, gave a history of recurring epistaxis for a number of years, in fact as far back as he could remember The hemorrhages were usually quite severe and at times difficult to check They usually followed blowing the nose or any unusual physical exercise such as dancing, playing tennis or ball, as well as mental or physical strain The bleeding would sometimes occur several times daily, again intervals of weeks would be between the attacks The patient since early childhood had been under the professional attention of a very experienced physician who looked upon the epistaxis as the local expression of some undeveloped cardiac lesion, and who informed the patient that the bleeding should be looked upon as a safety valve The patient had therefore been subjected every six months to a careful examination of the heart and lungs I first saw this patient in January, 1893, he was tall, thin and anemic He declared his nose felt free and unobstructed, that he never suffered from catarrhal symptoms, in fact, if it were not for the epistaxis would feel in the best of health On examination, a deviation to the left of the anterior portion of the septum was seen The deviation was quite angular, projecting about a quarter of an inch into the left nostril Over the projection the membrane was adherent, pale and scarred At the base of the projection the blood vessels were dilated On its anterior surface was found a round ulcer about one quarter of an inch in diameter covered by a crust Upon removal of this crust, bleeding occurred and the ulcer was seen to extend into the submucous tissue With the exception of a depression of the septum on the right, corresponding to the projection to the left, the nose and throat were in excellent condition Examination of the lungs, heart and liver, as well as the urine, showed absolutely normal conditions Upon questioning the patient confessed to occasionally picking the nose but declared himself unable to always abstain from the habit

Operation for the removal of the septal obstruction was advised and carried out in January, 1893 In about a week the patient was allowed to return to his home in a neighboring city Reports received from time to time showed subsequent absolute freedom from epistaxis although the patient now indulged in all the sports of a college student A note from my case book dated February, 1894, says that he has been entirely free from nasal hemorrhage since the operation There has been great improvement in his general health with considerable body development during the year About this date, while sparring, the patient received a violent blow upon the nose This caused renewed hemorrhages with some return of the septal deformity which, however, was easily corrected, and a recent report states that there has been entire relief from all epistaxis

In most of the cases observed the epistaxis was of rather a mild degree, but the following cases will illustrate how very severe the affection may become

Case 3—Mr P K, age 50 years, who consulted me in March, 1894, stated that since boyhood, he had had on an average three nasal hemorrhages daily These always were very severe and lasted from five to thirty minutes He had noticed that the bleeding usually followed picking or blowing the nose Of late years any mental or physical excitement would also cause it This patient was very anemic, and suffered from all the symptoms of that condition He stated that he had always been considered a "bleeder" Upon examination the septum was found to have an up and down S shaped deflection extending quite forward, with considerable thickening at the base On the anterior surface of the deflection were several small ulcers in each nostril The blood vessels of the mucous membrane covering the septum were varicose The nasal and pharyngeal mucous membrane appeared pale and sodden, with considerable secretion of mucus The posterior portion of each lower turbinated body was hypertrophied This patient acknowledged that he had been in the habit of picking his nose all his life When requested, he gave a demonstration which presented a vivid picture of the finger-nail scratching the septum Operation was recommended, but refused There was no difficulty in healing the ulcers, and causing the epistaxis to cease The patient was dismissed with a caution about picking the nose

Case 4—Mrs E F, age 38 years seen by me in December, 1894, gave a history of having had former nasal hemorrhages of a severe type and frequent occurrence, which condition had lasted fifteen years, and then about five years ago had ceased According to her recollection the bleeding was usually from the right nostril About three months before consulting me the epistaxis returned, this time apparently from both nostrils The hemorrhages however, were not so severe or frequent as formerly Examination showed an S-shaped deviation of the septum, running antero posteriorly The anterior projection of the S was well forward, to the right, while the posterior projection extended into the left nostril and further back Through the anterior curve a round perforation of about three eighths of an inch in diameter had occurred The presenting surface of the posterior projection to the left, was the seat of an ulcer, covered with a scab, the removal of which at once brought on a hemorrhage There was considerable hypertrophy of the lower turbinated bodies, as well as advanced granular pharyngitis

[4] Treatment of Epistaxis, Vienna, 1886

The patient confessed to the nose picking habit The hemorrhages ceased upon healing the ulcers, and stopping her bad habits In this case, I have no doubt but that the perforation was due to chronic ulceration of the septum, and that the temporary cessation of the hemorrhages came when the first ulcer had entirely perforated The renewed hemorrhages were due to the ulceration on the left side

Treatment for Control of Hemorrhage—As the point of bleeding is usually at the anterior portion of the septum, firm and continued pressure of the nostrils with the fingers or a clamp may be quite sufficient to secure cessation The head of the patient at the same time should be held erect or slightly forward, the patient sitting in a chair or partly reclining on a lounge If such pressure is not successful, small pieces of ice thrust into the bleeding nostril, and applied to the corresponding side of the nose, or cold applied to the spine, aid in checking the hemorrhage Again, full strength peroxid of hydrogen dropped into the nostril, or a plug of cotton saturated with the same and inserted, will usually form a clot sufficiently strong to check the bleeding Alum, 30 grains to the ounce of cold water, and sniffed up the nose, or applied by means of an atomizer, dropper, or on pledgets of cotton can be recommended Cocain in 4 per solution used in the same manner, and quickly followed by a 3 to 6 per cent freshly made solution of antipyrin, at times is quite successful, although care should be taken lest the depressing effect of the drugs add to any existing prostration If the patient seeks medical assistance, the bleeding point should be sought for, and is usually very easily found It may then be touched with copper sulphate or silver nitrate These may be used in solid form or in solutions A 5 to 10 per cent solution of silver nitrate applied on a small swab to the bleeding surface and held in position is usually quite effective At times it may be necessary to resort to the cautery, using the galvano-cautery, or heating the end of a probe in the flame and touching the bleeding point Such cauterization is quite successful, but renewed hemorrhage may occur upon separation of the slough At times it may be necessary to plug the nostrils Certain internal remedies may be used in addition to the local treatment Of these remedies ergot is the best, and may be given in repeated small doses, by the mouth or hypodermically Gallic and tannic acid, acetate of lead, sulphuric acid as well as the astringent preparations of iron may also aid in checking the hemorrhages

Treatment to Prevent Recurrence—The patient should be strongly urged to avoid picking the nose, and to use warm washes and oils to remove crusts and accumulations of dust The surface of the ulcer should be coated over by applying copper sulphate, or silver nitrate, or a varnish of balsam of tolu dissolved in ether The local use of the ammoniated mercury ointment, one half strength, or carbolic acid (2 to 5 per cent) in albolene or cosmoline, and insufflations of acetanilid, or iodoform, with or without morphia, can be recommended

With such treatment I have usually had but slight difficulty in healing the ulcerations and preventing epistaxis If the patient can abstain absolutely from picking the nose, this treatment may be all that is necessary The desire to pick the nose clear from the deposits of crusts that will form around the septal deformity from time to time is, however, almost irresistible and in my experience the recurrence of the hemorrhage is almost invariable It is therefore my usual custom to advise operative procedure for cure of the existing septal deformity and thus remove the offending cause Removal of the projecting portion by means of the nasal saw, shave, gouge, etc , is usually all that is necessary If the deviation is very marked, or if the hemorrhages come from the concavity of the deflection, it is advisable to fracture the septum and restore it to a normal position The permanent relief from epistaxis that I have invariably succeeded in obtaining from the performance of these slight operations has led me to strongly recommend such procedure, even when the hemorrhage is slight and of comparatively infrequent occurrence

1929 Chestnut Street

DISCUSSION

Dr J E H Nichols, of New York—The percentage of cases showing chronic atrophic rhinitis seems to me rather small as in my experience I have found it very large We almost always find the atrophic condition present with deviations of the septum, because of the patency of this non-occluded nostril Facial movements often cause hemorrhages by reason of the patient's effort to dislodge the crust formed in the vestibule and relieve himself of the feeling of tension caused by the dryness I have seen hemorrhages start from this cause A case under my observation at the Manhattan Eye and Ear Hospital exhibited this, she had been under treatment for two months at the Roosevelt Hospital for systematic causes, the atrophic condition being entirely overlooked Treatment directed to softening the membrane relieved the hemorrhages, and she has had none for four months I use largely an ointment called the unguentum nasalis which is of 10 per cent ichthyol and 5 per cent, eucalyptol in vaselin This is used twice or three times a day

Dr Woolen—said nose picking was not a habit and a bismuth vaselin salve applied at night stimulated healthful secretions and ease of cleansing and therefore, freedom of accumulation of irritating causes After all, in controlling hemorrhage, the formation of clot is the matter of prime importance, and this is most admirably secured by insuflating dermatol, and inserting a film of cotton along the inferior meatus, as foundation for clot, dermatol being both an hemostatic and antiseptic

Dr Loeb—I desire to call attention to perforation of the septum as a cause of recurring epistaxis A patient came under my observation who presented a large perforation of the septum and who suffered greatly from recurring nasal hemorrhages and from headache Treatment bearing upon a coincident cardiac condition had been used for some time by a practitioner in the hope of cure The use of nitrate of silver and oily spray entirely relieved her Another case presented a very sharp projection which forced its way through the mucous membrane upon exertion and after piercing the nose Removal of the spur entirely cured the condition

Dr Howard S Straight of Cleveland—The importance of very careful examination of the cartilaginous septum in all cases of frequently recurring nasal hemorrhage has been impressed on me during the last year I believe a slight ulceration of the mucous membrane the cause of the hemorrhage is often overlooked The connection between a slight devition of the septum and the ulceration of the triangular cartilage has not impressed me as of so great importance as expressed in the paper The writer has done the Section a favor in calling especial attention to this condition of affairs Just what importance to attach in a nasal disease of any form to a slight deviation of the septum, is a question in my mind To assume that the deviation accounts for everything is easy but just where to draw the line, the gods only know

Dr Van Sant, closing discussion—In regard to atrophic rhinitis being a frequent cause of habitual epistaxis, my experience does not agree with that of Dr Nichol It is true that the removal of an adherent crust in atrophic rhinitis may cause a few drops of blood, but this is so slight that I have not included such cases in my paper Dr Loeb considers perforation of the septum as a frequent cause Perforations have usually been found to be preceded and caused by chronic ulceration, indeed after the perforation occurs, the hemorrhages may cease although ulceration around the margins of a perforation may continue the epistaxis In such cases the best treatment is to heal the ulceration before perforation takes place In regard to the use of salves, nitrate of silver, etc, used by Dr Woolen I have already said such means will usually heal the ulceration and if the patient will absolutely abstain from picking the nose the epistaxis may permanently cease Unfortunately the temptation to remove crusts where there is a slight septal deformity is usually too great for the patient to resist In replying to Dr Straight I think that operations for the removal of any existing deformity should be advised upon the ground of securing more permanent relief If by operation we remove the projecting part from the septum, dust and crusts will not accumulate The temptation to pick the nose is lessened and the septum is less liable to injury and subsequent ulceration

REPORT OF A CASE OF CARIES OF THE SPHENOID BONE

Read in the Section on Laryngology and Otology, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md, May 7-10, 1895

BY EWING W DAY, M D

PITTSBURG, PA

That caries of the bones at the base of the skull is rare, is, I think evident from the scarcity of literature on the subject I have been able to find but scant reference to the subject from the resources at hand For this reason I have ventured to come before you with the report of a single case of sphenoidal caries Its course was chronic, lasting for two and a half years Its beginning was obscure, for during the first year and a half, though seen by many of the most prominent members of our profession, no definite diagnosis was made, but the cause was assigned to malnutrition and neuralgia of malarial origin That the bone itself was first involved seems to me certain, for when the membrane over the sphenoid broke down, the carious process was already fully established The resulting cerebral abscess demonstrated at the post-mortem, probably dated from the time of the extreme and continuous headaches, and though the optic nerve was exposed to pressure, and pus was present in the cavity of the orbit, the eye, while frequently examined by Dr Willetts, never gave evidence of it, on account of the drainage into the nasopharynx through the sinuses in the bones

In the spring of 1892 I was asked by the attending physicians, Drs Emmerling and Anderson, to examine the patient, who in addition to a marked general debility and a train of obscure and indefinite symptoms, complained of soreness and pain in the pharyngeal vault

The patient, aged 55 years, was a prominent physician of Western Pennsylvania, with the following history in 1884, while operating on a patient supposed to be syphilitic, for hemorrhoids, he accidentally cut his finger, which, though promptly treated, was in the hurry incident to the operation, not cauterized In a few days a severe case of blood poisoning resulted, but no symptoms of syphilitic infection were apparent Later, the question arose as to whether there might not also have been a specific inoculation at this point His recovery was slow and his physical condition was never as it had been before the attack

Seven years after, in 1891, he showed signs of physical decline, although he continued his labors as lecturer and operator at the medical college and hospital but his efforts lacked that spontaneity so characteristic of him He spent that spring and summer in Europe and suffered so severely from frontal headache, that often it was impossible for him to carry out his plans At times he would weep like a child and was generally depressed and very homesick The principal physical symptom of which he complained at this time was a feeling of extreme chilliness After his return home he seemed to improve and went about his work with some of his old-time vigor, but that fall, symptoms of nasal rhinitis developed and he frequently sprayed his nose with a hand atomizer During the winter he had a severe attack of influenza which left him weaker than ever with severe frontal headache and more aggravated nasal rhinitis After this sickness his health always varied malnutrition progressed and the nasal affection and frontal headache continued At times he would complain of a lame hand, the result of the blood poisoning During the spring of 1892 his debility frequently obliged him to rest and no amount of medicine and care altered his condition He however, attended the meeting of the American Surgical Association at Boston, and consulted several physicians both there and in New York, whose diagnosis was neuralgia and malnutrition of a probable malarial origin Later, he went to the Cheat Mountains in hopes that the outing would restore his health As the warm weather approached, his work became more laborious to him and frequently he would remain in bed and refuse to see patients

At this time, when I first saw him, an examination of the nose and naso pharynx had not been made, medication being directed toward stimulating the appetite and overcoming the indigestion and nausea which had been prominent symptoms At times he seemed feverish, but never to a marked degree The pulse was always good An examination showed the vault of the pharynx swollen and inflamed, the mucous membrane having a superficially eroded appearance as if denuded of its epithelial layer There was marked chronic rhinitis, with stenosis, from distension of the venous plexus of the lower turbinates From this time on I saw the patient nearly every day up to the time of his death A short time after this while making an examination, a small carious area, at the spheno-vomer articulation was found, a piece of bone the size of a pea was removed with the adenoid forceps, and a diagnosis of caries of the sphenoid made

A consultation of physicians now held, resulted in the conclusion that his ailment was syphilis contracted at the time of the blood poisoning, the possibility of tuberculosis being excluded by a microscopic examination of the discharges He next took a trip East and consulted Drs Janeway, Gouley, Bryant and several others, concerning the probability of syphilis, without receiving any definite opinion

Mercurial treatment was persevered in unremittingly, and iodids, though thoroughly tested, were without effect, as he possessed an intolerance for them In September, tinnitus aurium, accompanied by severe pains in the right ear developed, though there was no change apparent in the tympanum, and there was also pain in the right frontal sinus This pain was so severe and persistent that the patient insisted there must be suppuration An examination proved it to be healthy, but foul pus was being discharged from the sphenoid and the region of the ethmoid and it was evident that caries was progressing rapidly

The swelling of the naso pharyngeal wall and the extreme sensitiveness of the throat rendered a full rhinoscopic view difficult, but an area of diseased bone 2 c m in length by 1 c m in breadth could be seen and it was evident that the body of the sphenoid and basilar process of the occipital bone were disintegrating At different times a quantity of carious bone was removed through the nostrils, with an instrument devised for that purpose, with no appreciable benefit Frequent cleansing of the nostrils and throat now became necessary to remove the pus which was abundant Through the winter of 1892 he became very feeble and occasionally morphin was necessary to relieve the pain On Jan 24, 1893, he was induced to take a trip to Florida in the hope that the outdoor life might improve his condition Dr Emmerling accompanied him and they stopped at Baltimore to see Drs Osler and Halsted, who gave the opinion that he was suffering from necrosis of the base of the skull, and thought that an operation, while doubtful might be of benefit, and that a trip South would improve his physical condition

During the first two weeks in Florida the patient improved markedly, the pus became greatly diminished and he could spend the whole day fishing He ate well and was able to walk long distances On a change of the weather, however, he contracted a slight cold and steadily declined in strength, suffering severe pains and having some symptoms of abscess of the brain He was brought home on April 1, very weak, appetite bad, constant headache, twitching of the left trapezius and muscles of the back of the neck, with sensory disturbances of the face The lymphatic glands on the left side, at the angle of the jaw had suppurated and were lanced, the resulting wound was exceedingly indolent, nearly closing at one time The caries had progressed steadily and there were sinuses in the sphenoid and basilar process that admitted the entrance of a small probe for 3 or 4 mm The pus was more abundant in the pharynx This flow was freer at times, giving relief from the pain for a few hours Ordinarily one-third of a grain of morphin was necessary twice daily Finally, the bladder became inflamed and catheterization was required To help the headache, frequent applications of the faradic current were made During this decline, his faculties were preserved to the last, the only mental aberrations being wild dreams under morphin

May 28, he was taking one third grain of morphin, two or three times a day, refused food on account of nausea when it was brought to him, and always vomited when lying on left side The gland that had suppurated now exhibited the character of a fungating ulcer and a bed-sore over the sacral spine was very painful and difficult to heal His eyes had a slightly crossed appearance, but he never complained of a diplopia

June 2, the bed sore was nearly healed, but the cystitis was much aggravated and regular catheterization was necessary A proctitis had also developed from use of the rectum for alimentation yet at this period he could walk to the lounge to have his nostrils cleaned or examined During the next ten days he failed much, until the early morning of June 13, when he was found trying to vomit and on questioning what had happened, he said the pus was running down his throat, some of it ran from the nose and he expectorated about an ounce His voice was peculiarly cavernous, having a nasal ring He was mentally clear for a time and had less pain, but was very pallid and the respirations increased Gradually he became comatose and died in a few hours

Post mortem —The head only was examined On removing the calvarium, which was not thicker than the average, the dura was found very adherent, especially to the frontal bones The adhesion was not uniform but in spots, elsewhere it was soft, thick and easily detached A pachymeningitis with passive congestion, was exhibited over the frontal and temporo-sphenoidal lobes of the brain On dividing the dura and falx cerebri transversely, the pia and arachnoid were found to be hyperemic on both sides with considerable edema of the right side Stripping the dura forward it was found adherent to the anterior pole of the cerebrum, by a lepto meningitis The left hemisphere was congested, but its consistency and color were normal, while the right was soft, putty-like and nearly diffluent As the brain was lifted out of the fossæ the adhesion of the membranes to the frontal, and temporo sphenoidal lobes was seen, and an abscess cavity springing from the center of the right wing of the sphenoid entered the temporo sphenoidal lobe This abscess had dissected its way between the dura and the sphenoid back of the middle lacerated foramen, up over the petrous portion of the temporal bone as far back as the internal auditory meatus This abscess, which was of the size of a walnut, traced medially, dipped beneath the structures which passed through the foramen rotundum and pierced the base of the right wing of the sphenoid, entering the sphenoidal and spheno ethmoidal cells into the naval cavity The walls of this abscess in the brain were soft, without any resemblance to brain matter and the entire hemisphere was exceedingly soft

By dividing the lesser wings of the sphenoid, the orbital and nasal cavities were exposed from above, pus was present in the orbit and it was found that a sinus led from the right side into the orbital cavity and connected with the anterior ethmoidal cells, and the abscess of the brain The entire body of the sphenoid and basilar process of the occipital bone were riddled with sinuses, exposing the external surface of the dura and leaving it as the only protection and support of that part of the base of the brain resting on the clivus blumenbachii The pterygoid processes and ascending rami of the palatine bones were carious and loose The vomer was entirely gone, as also the perpendicular plate of the ethmoid The cribriform plate of the ethmoid, the turbinated bones and lesser wings of the sphenoid were intact Both antrums, the frontal sinuses and the turbinates were free from disease, while the post-pharyngeal wall was intensely congested and thickened to the extent of half an inch, nearly closing the isthmus of the naso-pharynx This thickening of the mucous membrane also extended to the sides of the nasopharynx, closing or obstructing the Eustachian tubes The abscess and excavated bony base at the floor of the brain brought vital parts into great danger The carotids, cavernous sinuses, crura cerebri and other structures were within a few cells distance of infection

The pus that poured from the nose and into the throat on the morning when he died, came from this abscess of the brain and the consequent passive congestion and anemia of the brain was the *coup-de grace*

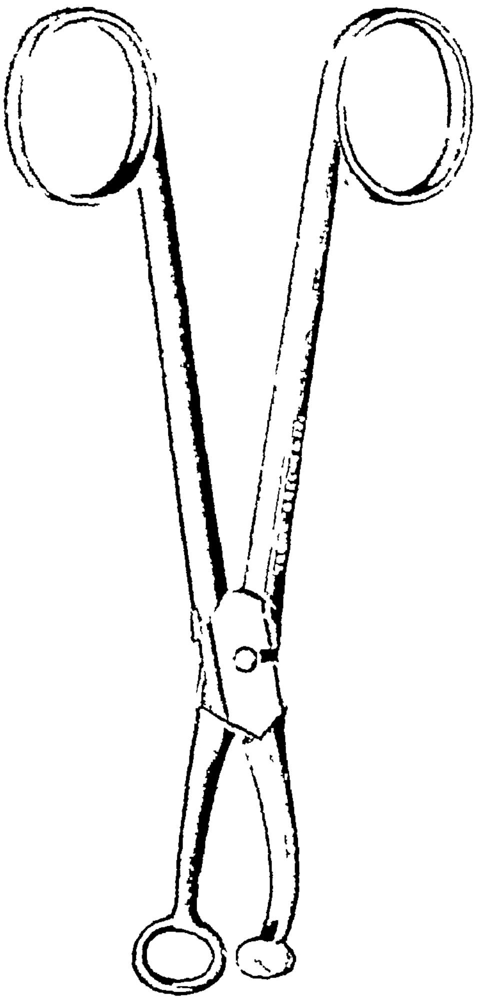
NEW SEPTUM FORCEPS

Read in the Section on Laryngology and Otology at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md, May 7-10 1895

BY A J ERWIN, M D

MANSFIELD OHIO

Having long felt the want of an implement for the correction of the deviated septum, I had these forceps made by Truax, Greene & Co, which I find to be very useful and convenient The male blade being 4 m m less in its diameter than the inside of the ring blade, it does not cut the cartilage while reversing its convexity, it produces at most, a kind of green stick fracture of the septal periphery, which makes it easy of support In most cases a hard pledget of cotton will keep it in place as required for a few days will keep it in place as required for a few days Sometimes you will find it better to use the pin One size, just as large again as this cut, will answer for every case, except for children, and they do not need it



Dear Doctor —Please direct the attention of your friends to *our* JOURNAL We will be pleased to send sample copies to any names you may suggest

ON THE LOCAL AND GENERAL CONDITIONS THAT CHANGE CORNEAL CURVATURES

Read in the Section on Ophthalmology, at the Forty-sixth Annual Meeting of the American Medical Association Baltimore, Md, May 7 10 1895

BY LOUIS J LAUTENBACH, M D, PH D

PHILADELPHIA

Theoretically, astigmatism *may* be occasioned by any irregularity of curvature or of structure of any of the tissue layers of the eye lying in the course of the visual axis, but practically, it is usually lenticular or corneal in its origin and is an irregularity of curvature *and not of structure* Of these the corneal variety is by far the most common, while the lenticular form is rarely sufficiently prominent to interfere with vision

In this paper I will confine my attention to regular astigmatism developed in the cornea, and will but incidentally notice lenticular astigmatism Formerly, regular astigmatism was considered a congenital deformity, sufficiently fixed and definite to remain ever *in its original condition*, *excepting* when modified by some violence, traumatic or inflammatory exerted upon the cornea, or by some change in the lens substance from degeneration or injury Later, when the opinion began to be expressed that perhaps the astigmatism was a little more variable than had been supposed, these changes when admitted, were attributed to *alterations in the lens* substance or in its curvatures, from distorted or spasmodic action of the ciliary *muscle*

In my opinion, many and various are the causes of astigmatism and of its variation I will attempt to explain how normal astigmatism develops and the influences which determine its origin and extent, and will also attempt to show that while astigmatism is nearly always present congenitally, with its seat in the cornea, this corneal astigmatism is not by any means constant throughout life, its degree and axes being subject to variations These variations may be many, frequent and even sudden, due to a great variety of causes, constitutional as well as local

Burnett[1] speaking of reported cases of progressive changes in the degree of astigmatism and in the direction of the principal meridian says "We can not positively exclude a change in corneal curvature, but it is most probable that the change is due to alteration in the shape of the lens, either from changes in its substance or from a modified action of the ciliary muscle"

Fuchs[2] says that, "The cause of regular astigmatism in the great *majority* of cases is a congenital irregularity of the curvature of the cornea" He also writes "Acquired astigmatism may have its cause in the cornea or in the lens The former *variety* occurs when the curvature of the cornea has been altered, either because of disease affecting it or still more frequently because of operations The lens gives rise to a regular astigmatism when it is obliquely placed, as for example, in subluxation"

Noyes[3] says that regular astigmatism "is chiefly dependent upon abnormal curve of lens or want of homogeneousness in the lens" He acknowledged that "some rare cases of astigmatism are acquired, but as a rule the regular astigmatism of the cornea is congenital Acquired astigmatism in the cornea when no opacity exists, comes from conicity of the membrane or happens after tenotomy of the muscles, or after wounds of the cornea, iridectomy and extraction of cataract "

Schmidt-Rimpler[4] writes of regular astigmatism as follows "As a rule, the affection is congenital It is found occasionally in corneal opacity," and " from ulcerations and ectasiæ, particularly keratoconus It is especially frequent after cataract operation and may also occur after iridectomy "

A theory extensively advocated in the past, is expressed by Javal[5] as follows " The meridian of greatest refraction corresponds to the shortest diameter of the skull " This theory places the burden of the formation of astigmatism entirely upon the development of the osseous structures and when these are fixed, no change of astigmatism can occur save from injury or disease

Corneal curvature, and, consequently, corneal astigmatism when present, is the result of a number of forces more or less antagonistic, exerting their powers upon the corneal texture The cornea, a dense elastic tissue, is inserted as a watch glass in the front of a softer spherical body, the eyeball which in turn rests upon a cushion of fat, being held in position by the recti and oblique muscles, aided by the orbicularis palpebrarum and, to some extent, by the optic nerve and orbital tissues The sphere is made sufficiently tense to retain its normal shape by the rigidity of its walls, the pressure of its semi fluid contents, and a resistance and muscular plane situated immediately posterior to the insertion of the cornea—I refer to the iris and ciliary body with the lens and its capsule The corneal structure being denser than any other part of the sphere's walls, offers more resistance to pressure changes

The pre-natal cornea is subjected to pressure from within and without The corneal surface is the result of these opposing forces The pressure from within the eye, during the period of growth, stretches the tissues of the eyeball in all directions In consequence of this, the cornea being the densest and most rigid portion thereof, is subject to the least change in curvature, but having the radii of its curves increased, the support of the recti muscles and of the orbicularis still further opposes this flattening, the oblique muscles and to a limited extent the levator palpebræ aiding it Among the other influences working at this time, is the resistance offered laterally and posteriorly, to the growth of the ball and to the play of the various forces indicated, by the walls and contents of the orbital cavity If the equatorial resistance of the orbit be greater than normal, the corneal curvatures will in consequence be increased, while, *vice versa*, if too much pressure be exerted from behind the eyeball, they will be decreased and the cornea flattened The corneal curvatures at birth are but the resultants of these conflicting forces, and through life these same factors play even as important a part in the retention or in the alteration of its curves, except that the forces applied are apt to be more irregular in their action, while the cornea having become fairly rigid and having assumed a more fixed and definite form, more strenuously opposes changes of all kinds, whether applied from within or from without the globe All forms and varieties of astigmatism are the direct result of the action of these various influences and from the degree and axis of the astigmatism, we can, by careful study determine the exact location of the supra- and subnormal forces

Presuming that the corneal resistance remains constant, if the internal pressure be above normal, the corneal curvatures become more flattened This flattening is usually more marked in the vertical meridian, as in this meridian the recti muscles normally offer the least resistance, and the orbicularis palpebrarum being at the same time by the increased bulging forward of the eyeball, thrown into a position to exert less than the normal pressure In conditions where the intra-ocular pressure is diminished, exactly the opposite conditions result, the corneal curvatures increase—the vertical meridian becoming usually the more convex—the orbicularis again playing an important part in this change

If the orbicularis is more than usually powerful, or too active, the vertical meridian becomes more markedly curved than usual, if this muscle be too weak, it is lessened If the levator palpebræ are unusually developed, the vertical meridian is prone to become flattened If the vertical recti muscles are more developed than usual, the normal astigmatism of an eye, namely, astigmatism with the rule, in which the curve in the vertical meridian is greater than in the horizontal, is apt to be increased, whereas if there is a want of development or any weakness in these muscles, the vertical meridian becomes more flattened If the horizontal external pressure on the eye be greater than normal, if one or both the lateral recti muscles be too strong or in a spasmodic state, the curve in the horizontal meridian is increased, and if they be either weakened or paralyzed this curvature will be diminished The effect of the oblique muscles is to twist the principal meridians away from their usual horizontal and vertical positions and to flatten all the curvatures, especially those near the horizontal meridian

To more thoroughly appreciate corneal changes as affected by the recti muscles, a study of their insertions may prove valuable Beginning with the weakest of the recti, the superior, it is inserted[6] 3 3-5''' behind the cornea with its inner end 1''' nearer the cornea than the outer, while the inferior is inserted 3''' behind the cornea, ½''' inward from the end of the vertical meridian and with its inner end 1''' nearer the cornea than the outer, while the inner, the thickest of the straight muscles, is inserted 2''' back of the cornea, and the outer,[7] the strongest and longest, is inserted 3½''' back of it These individual peculiarities of length, strength, and especially of the insertion of these muscles prove interesting, not only as regards the relative weakness of the vertical recti, as instanced in the fact that both these recti are smaller and their insertions farther removed from the cornea than the horizontal, but also in the study of the origin and development of the not infrequent cases of astigmatism in axes not exactly corresponding to the horizontal and vertical

The actions of the recti muscles, I have illustrated by constructing a series of small rubber balls having white varnished surfaces, with tapes glued to them to represent the muscles, and then drawing the various tapes with different degrees of strength, measuring the changes in curvature by means of the ophthalmometer I used the same means to illustrate the changes produced by increased intra ocular pressure with the expected result, and constructed artificial eyelids on these balls, and by the observations confirmed the theoretic consideration Another method which I employed to illustrate the same subject was by mounting the eyes of hogs and pigs in the guillotine of the ophthalmometer and then producing contraction of the muscles and measuring the corneal radii This series of experiments, while entirely confirmatory of the results above given, are not yet in such shape as to allow of a full tabulated report

To illustrate the action of the lids—the orbicularis palpebrarum and the relation of its actions to that of the recti muscles—I have constructed two rods of equal length one to represent the horizontal meridian, the other the vertical On the first, you see weights suspended from each end These weights represent the pulling effect of the recti muscles On the other rod, you observe the end weights are smaller, and sliding up and down these rods are two extra weights which you will observe I have so arranged that I can add to, or subtract from, as necessary The end weights represent the pulling force exerted on the cornea by the vertical muscles, while the sliding weights represent the variable pressure as exerted by the lids—the orbicularis as opposed by the levator palpebræ The nearer the center of the cornea this muscle exerts its influence, the greater its power, so as I move this weight toward the axis on which I have the rod suspended, the more weights do I place upon it, and the farther I remove this slide from the center, the more weight do I remove from it This will illustrate the conditions which prevail in all eyes subjected either to extra intra-ocular pressure or extra post-ocular pressure, or in affections involving the orbicularis muscles As the pressure increases, the lids are thrown back from the eye away from the corneal pole, and this muscle is placed at a disadvantage and is not able to exert its full muscular influence Extra action of the levator palpebræ brings about the same condition

The value of these actions being seen in the determination of the radii of curvature and the production of the principal meridians of the cornea, variations from the normal can in each individual case be explained by a consideration of the conditions present, as contrasted with those normally found As before mentioned, increased intra-ocular pressure as well as increased post-ocular pressure, occasions a flattening of the curves, whereas if either of these be below normal it will result in an increase in the curvature in the first—the vertical meridian is apt to be the more flattened—and the latter more curved, whereas any increase of pressure either lateral, from the orbital walls, or, as exerted by the muscles, or from in the front, by the lids, results in an increased curvature, the meridian of greatest increase being in the line of greatest force

While normal corneæ are under the influence of these antagonistic muscular and other forces, they usually show little or no sign of curvature changes, but when a change of this kind does occur without any definite and distinct cause, it is very slight, slow and regular, and is almost always an increase in the curvature of the vertical meridian as contrasted with the horizontal This relative increase in the curvature of the vertical meridian may be considered as normal; it seems to be occasioned by a gradual giving way in this meridian, due to the constant slight excess of pressure of the vertical recti, plus the lids over the lateral recti, and to the slight weakness of the internal rectus so often produced in modern life by the intellectual pursuits, overtaxing the lateral muscles, and possibly to some extent leading to a gradual change in the ciliary muscle from over-use

In the case of abnormal corneæ where the corneal tissues are below par, either from local inflammations, from interference with the nutritive supply from pressure, or from constitutional diseases, these corneal disturbances are not slight, slow and regular, but are often sudden and violent, the curvature and axes often varying as one or the other of the muscles or series of muscles is brought into action

We can then for convenience arbitrarily arrange non-inflammatory changes in corneal curvature into two classes

1 Those occurring in well nourished normal corneæ where the changes of radii or axes or both are slow, regular, but progressive, and

2 Those occurring in corneæ poorly nourished where the changes are rapid, irregular and variable

Since reading a paper on corneal curvature[8] before the Philadelphia County Medical Society in June of last year, I have been pursuing the subject in both a clinical and experimental manner My clinical work has served but to accentuate the results therein expressed, while the experimental work so far as it has gone, confirms the clinical observations In studying the cases clinically, I rely mainly on my ophthalmometer, but to some extent on skiascopy and the subjective testing with glasses with the accommodation paralyzed

Considering the latter method first, I have found that in cases of suspected variability in corneal astigmatism, suspected because the ophthalmometric measurements indicated it, that the testing of the refraction almost invariably showed absence of marked improvement of remote vision, and that the principal axes were either not clearly defined, or perhaps not at the ordinary intervals of 90°, the results being uncertain, both as to the axes and the amount of vision obtained These results appeared not only after the thorough use of homatropin according to the method indicated below,* but even after the thorough and persistent use of atropia In these cases the skiascopic observations gave similar results as to the uncertainty of the axes and in the amount of astigmatism

My method of using the Javal-Schiotz ophthalmometer I have already indicated in a paper[9] read before the Pan-American Medical Congress in May, 1893 I use electric lights as illuminators and thus have practically the same illumination present in each case The instrument is placed on a firm non-vibrating stand The patient seats himself before the instrument, his feet resting firmly upon the floor with his arms upon the table He then places his chin upon the sliding rest, which is raised or lowered so as to bring the eyes to the proper height and on an absolute level Having attended to these details, the head is strapped firmly to the head rest The patient is directed to look at a 5 mm square placed upon the center of the field glass of the telescope, and the instrument is adjusted so that the exact center of the field is occupied by the mires in apposition In some cases, a want of accuracy is occasioned by the drying of the cornea while under observation, which I obviate by the use of a weak solution of salt,

---

* In ordering homatropin, I always give a printed prescription as below, and ask that the directions be carefully observed, using five doses of the drops in the evening and five in the morning, the examination taking place after the last instillation

R Homatropin hydrobrom gr s s
Aqua rosa m xv
M Sig Eye drops One drop in the outer corner of each eye every half hour for two hours in the evening, and every twenty minutes the succeeding morning

again the same difficulty is caused by profuse conjunctival discharges which is overcome by using castor oil in the conjunctival sac, rubbing thoroughly over the cornea

My ophthalmometric observations have been made on over 3,000 eyes, and my attention was early called to the fact that corneal meridians and their axes were by no means constant Not only did I observe them sometimes to vary from day to day, or from week to week, but also that these changes would occur during the course of a few seconds I have found the corneal astigmatism to change from 2 to 3 dioptres in from eight to ten seconds, and the axes as much as 25° during the same period, this occurring in corneæ not inflamed and not associated with any eye inflammation

(See reference 8) (Case 1 illustrates these violent changes)

Laqueur[10] made the same observation, although he did not record such extreme cases as I have noted I have invariably found these quick and instantaneous changes associated with depraved conditions of the general system, having observed it in advanced cases of syphilis, in the scrofulous and the tubercular, in those subject to gout and rheumatism, especially the latter, after scarlet fever, diphtheria, typhoid fever and pneumonia and in those suffering from chronic diarrhea and exophthalmic goitre Noyes writes "It is not rare to discover, as Laqueur pointed out, that the curve of the cornea is not constant It sometimes changes as we look at it, we note the images approach or separate instead of remaining still" Continuing "They exhibit these oscillations under the action of the lids, and also if the upper lid is lifted off the globe, under the action of the motor muscles Drawing on the lids at the outer angle will increase the corneal curves greatly" Laqueur[10] observed that the traction on the upper lid, whether toward the temple or the nose, occasionally produced flattening of the horizontal meridian and increased curvature of the vertical meridian by pressure on the globe, so that regular astigmatism of from 2 to 4 D developed

I early observed that the corneal measurements were sometimes altered after the accommodation had been paralyzed After noting this phenomenon a number of times, I made a series of experiments 1, taking corneæ whose meridians remained constant from day to day, I would paralyze the accommodation and while, often without any appreciable effect, when any change was occasioned it was usually of a decrease in the corneal curves with, often, an increased development of astigmatism if with the rule, and a diminution when against the rule (Case 2 illustrates the experiment)

It would seem from these observations that the ciliary muscle is one of the factors in the determination of the corneal curves

The second series of experiments consisted in taking corneæ with constant curves and, while measuring them on the ophthalmometer, throwing a pencil of light on the eyes, I found that changes in the meridian frequently occurred and that these changes were usually in the nature of an increased curvature with, often, a lessening of a degree of astigmatism when with the rule, and an increase of it when against the rule (Case 3 illustrates the experiment)

So far as I know, this theory of the action of the ciliary muscle in modifying corneal curvatures is opposed to the views of all who have written on the subject, and yet these observations were so frequently and accurately made that I am sure some modification of the corneal curves must be attributed to the action of this muscle The ciliary muscle serves, no doubt, as a muscular framework to support the eyeball immediately posterior to the cornea, when the muscle is in use it acts as a drawing string within the ball, constricting it anteriorly In paralysis of the accommodation, the internal muscular force being removed, the corneal elasticity and the eye tension serve to increase the corneal radii If the accommodative paralysis be long continued, the vertical meridian gives way proportionately more and more, as the lid pressure is gradually removed a greater distance from the corneal pole

As previously indicated, corneal changes are of two kinds It is in sound corneæ subjected to unequal pressure, that we find the first class of changes before mentioned—slow, irregular and progressive variations in corneal astigmatism In unhealthy corneæ we have our second class of changes—that of the irregular, rapid and variable A practical fact of some importance is that in this latter class of cases the symptoms of poor vision, head pains, vertigo and sick stomach are often extremely severe and can only be relieved by putting the cornea at rest, which is most readily accomplished by absolutely paralyzing the accommodation, in this way preventing the use of the external muscles with their consequent constant disturbance of the cornea The monocular double vision occasionally observed, is undoubtedly in a not inconsiderable number of cases, thus produced

According to Dobrowolsky[1] the irregular contraction of the fibers of the ciliary muscle changes the refraction of the eye by its influence on the curvature of the lens, while Wallace[13] speaking of the Javal ophthalmometer says "That variations of accommodation in the patient's eye do not modify the degree of astigmatism The curvature of the corneal meridians remains the same during active accommodation as during the passive state" Burnett[14] also seems to consider the ciliary muscle as exercising no effect on the cornea, as he says "The accommodation in its entirety can not affect the amount of astigmatism, though it greatly modifies its general character" It would seem however from the reports of Dobrowolsky, Javal[15] and others that "there can be a partial contraction of the muscle of accommodation, producing a lenticular astigmatism, the effect of which would be either to create a new, or increase an existing astigmatism, or to a greater or less extent, to neutralize that of the cornea"

I hope I have shown how such an apparently slight influence as the contraction or paralysis of the ciliary muscle may influence corneal curvature, and consequently its astigmatism, so I will refer more briefly to the greater influences that govern its meridians I will premise by asserting that corneæ are influenced, all other things being equal, in proportion as their development has been deficient, or their nutrition insufficient Well developed and healthy corneæ of thoroughly healthy and robust patients are, according to my observations, rarely affected by any but the most marked and violent local disturbances, whereas corneæ deficient in resisting quality, either as the result of a previous inflammation or of an existing disturbance, and the corneæ of those suffering from constitutional dyscrasia, of those convalescent from acute febrile diseases, and of those who have been subject to the ravages of prolonged chronic disorders, are affected by the slightest local derangement—the least want of that exact balance of the various forces that so thoroughly control the shape and motion of the eyeball, whether this be an increase or decrease of orbital contents, or some variation in the tonicity of the eye muscles, some difference in the amount of pressure exerted upon the ball by the lids, some variation in the strength of the ciliary trestlework, or some change of pressure within the ball In short, any change of pressure within or without the eye, may and often does alter the corneal meridians, always does so in weak corneæ, and if the want of balance be sufficiently long continued, will do so in sound healthy corneæ

In dealing with wounds of the corneal tissues, it can be easily understood how any abrasion or injury of any kind, affecting the deeper layers, can be readily followed by a change of corneal curvature If the wound be sufficiently extensive or near the pole, its effect upon the visual region of the cornea will be considerable and give rise to a marked disturbance of the corneal meridians We all expect to have marked corneal changes develop after an iridectomy or a cataract extraction We often find the astigmatism after a cataract extraction to be increased 10 to 16 D or more, the meridian of least curvature being at right angles to the line of incision As cicatrization and absorption advance, the astigmatism gradually diminishes until it approaches the normal (Case 1 illustrates this)

Corneal inflammation involving the fibrous and elastic layers is always followed by changes in corneal curvature these changes depending upon the extent and depth of the inflammation, and its practical importance to its proximity to the visual line Staphylomata show, in an exaggerated degree, the effects of the intra ocular and external muscular pressure on a weakened corneal texture—the staphylomata being the result of these antagonistic forces

My experience after advancement and section of the recti muscles has been to find a marked change in the corneal astigmatism In advancement, the meridian corresponding to the plane of the advanced muscle has its radius diminished on account of the increased tension thereon exerted, while the opposite meridian is occasionally flattened In tenotomy, the meridian in the plane of the muscle operated upon is flattened, while the opposite meridian is often more curved Noyes[16] calls attention to this acquired astigmatism of the cornea, following tenotomy of the muscles

Pterygii occasion irregular flattening of the meridian of their growth which increases as it advances and which usually subside if the pterygium is removed sufficiently early (Case 5 is an illustration) Noyes[17] gives us a practical lesson when he writes "I have formerly been indisposed to remove pterygium until it made appreciable advances toward the region of the pupil, but having noticed that under its influence astigmatism arises, I now remove it when not more than 2 millimeters beyond the limbus "

As illustrating the changes of the corneal curvatures from pressure exerted within the eyeball, I will for a moment direct your attention to the well known changes occurring in the course of glaucoma The importance of these observations consists in the fact that in fully three fourths of the cases of the disease there is a prodromal stage lasting often for months and even years, and that if the corneal curvature change, presenting itself in this stage be recognized, (and it is among the earliest of symptoms) the seriousness of the disease is often averted As a glaucomatous attack begins to cause increase of pressure within the eyeball, it not only presses all the structures in an outward direction, but by reason of this very pressure interferes with the corneal nutrition The corneal images as seen by the ophthalmometer, become more or less indistinct and later quite hazy, and the curvature of the principal meridians change, the horizontal becoming more curved and the vertical more flattened, while often the axes assume new relations to each other, not remaining 90° apart As the disease advances, the changes become gradually greater until often there is developed a change of as much as 3 or 4 D , the astigmatism developing against the rule (Cases 6 and 7 show this change)

The same change is observed in glioma of the retina, sarcoma of the choroid, and sometimes follows vitreous inflammation and hemorrhage into the retina I have observed the same change in some cases of exophthalmic goitre (Case 8)

As illustrating changes occasioned by variations in the capacity of the orbit, I have observed in some cases, when corpulence was increased, a change in the corneal curvatures, which disappeared after the excess of fat deposited in the orbit had been absorbed Orbital tumors, such as exostoses, fibromata, sarcomata, lipomata, myxomata, melonomata, cysts, etc , have a tendency to alter corneal curvatures, their influence being most observed in the meridian of greatest pressure, their effect upon the cornea being entirely dependent upon the lines of greatest increased force

In *conclusion, it may be said*

1 That regular astigmatism is always corneal or lenticular, but usually the former

2 That regular corneal astigmatism is the result of a variety of forces, acting upon the cornea, these forces being usually so accurately balanced as to result in the production of normal astigmatism, a low degree of astigmatism with the rule

3 That these forces consist not only of the muscles of the eye and of the lids, but that the orbital resistance, the intra-ocular pressure, and even the ciliary muscle are concerned, as well as the tonicity of the cornea

4 That anything that interferes in any way with the accurate balancing of these forces, results in the production of astigmatism, modified or altered in accordance with the excess or deficiency of the power exerted

5 That the inequality of forces, when long continued, affects healthy cornea, giving rise to slow, regular, progressive changes in the axes or degree of astigmatism or of both

6 That these unequal forces acting upon corneæ weak from local or constitutional causes, produce more rapid and violent, often instantaneous, changes in the axes or degree of astigmatism or of both

7 That any local condition that interferes with the texture or nutrition of the cornea predisposes to changes in corneal axes and curvatures

8 That any constitutional affection in any way modifying the general circulation and thus changing the corneal nutrient supply, predisposes to these changes

9 That any force acting unduly on the cornea should have its action modified as soon as possible

10 That corneæ under the influence of unequal forces, should be put at rest at the earliest possible moment

11 That corneæ weak from general or local conditions after being put at rest, should be promptly and efficiently treated in order to render them strong and healthy

12 That in many eye affections, a study of the corneal changes will serve to shed light on otherwise obscure conditions

13 That by carefully studying these corneal curvature changes in connection with the kind, degree and axis of astigmatism, indications for the treatment of the eye muscles will be obtained that were otherwise impossible

Case 1 —Illustrating sudden changes in amount of corneal astigmatism and in the axes of curvature Miss N B, aged 21 years, pale, poorly nourished, blonde, of a scrofulous type, was first examined by me July 7, 1893 V R R E, 6–15, L E, 6–60 Ophthalmometer, R E, images hazy, indistinct, axes variable above and below 90° Astigmatism amount varying from 0 25 to 0 75 D L E, hazy indistinct, axes variable, 15° above and below 38° and 120°, amount varying from 1.25 D to 3 50 D Re-examined July 11, 1893 R E, axes variable to either side of 80° and 170° amount varying from 0 25 to 0 75 D L E, axes variable, 15° above and below 30° and 120°, quantity from 1.25 to 3 50 D The axes and amount continued to vary, gradually the extent and rapidity of variable becoming lessened as the girl's health improved under the influence of rest, tonics codliver oil and mercury Examination Oct 1 1893 indicated that the axes and curves were fixed, the ophthalmometric record being

R E, ax	90°,	amount 1–6 D,	corneal	radius	7 7½ m m
" ax	180°,	"	"	"	7 7⅔ "
L E, ax	125°,	" 1½ D,	"	"	7 5⅓ "
" ax	35°,	"	"	"	7 7⅞ "

Refraction under atropin, Oct 14, 1893, was found to be

R E, sp — 0 50 D ⊃ cyl — 0 75 D, ax 180°
L E, sp — 0 75 D ⊃ cyl — 1.25 D, ax 90°

The glasses ordered and which have given perfect satisfaction up to the present were, R E cyl — 0 75 D ax. 180° = 6–9, L E, cyl — 1 25 D, ax 90° = 6–9

Case 2 —Illustrating the effect of paralysis of the ciliary muscle on the curvatures of normal cornea Miss E W, aged 7 years R V R E, 6–30 L E, 6–30 Measured upon ophthalmometer gave the following measurements at three different examinations images clear and distinct, no varying in the axes or amount of corneal astigmatism Last examination, July 7, 1895

R E, ax 95°, amount corneal astigmatism 3⅓ D, corneal radius, 8 4⅓ m m, ax 5°, amount corneal astigmatism, 3⅓ D, corneal radius, 7 8⅛ m m

L E, ax 85°, amount corneal astigmatism, 3¼ D, corneal radius, 8 5¼ m m, ax 170° 3¼ D, corneal radius, 7 9½ m m

When examined Sept 9, 1895, under mydriasis complete, gave the following records

R E ax 95°, amount corneal astigmatism, 3 + D, corneal radius, 8 4⅓ m m, ax 5° corneal astigmatism, 3 + D, corneal radius, 7 8⅙ m m

L E, ax 85 D, amount of corneal astigmatism 4¼ D, corneal radius 8 6 m m, ax 175°, amount of corneal astigmatism 4¼ D, corneal radius 7 8⅓ + m m

As refracted by glasses the same day, the following result was obtained

R E, sp + 4 00 D, cyl + 3 00 D, ax 90°
L E sp + 4 00 D, cyl, + 4.00 D, ax 90°

Case 3 —Illustrating the effect of accommodation on the curvature of normal corneæ Miss M S, aged 23 years Examined on three occasions with a constant result Last examination Sept 9, 1894 as follows

R E, ax 103°, amount astigmatism 2½ D, corneal radius 8 3 4–5 m m ax 13°, amount astigmatism 2½ D, corneal radius 7 9 m m

L E, ax 75°, amount astigmatism 2½ D, corneal radius 8 4 1–5 m m, ax 165°, amount astigmatism, 2½ D, corneal radius 8 0 2–3 m m

These observations changed to the following when the light of a 16-candle power incandescent globe was reflected on the eyes

R E, ax, 103°, amount corneal astigmatism 1¾ D, corneal radius 8 3 2–5 m m, ax 13°, amount corneal astigmatism 1¾ D, *corneal radius 7 9 + m m*

L E, ax 75°, amount corneal astigmatism 2 — D, corneal radius 8 3⅞ m m, ax 165°, amount corneal astigmatism 2 — D, corneal radius 8 0⅔ m m

Case 4 —Illustrates the effects of the operation of cataract extraction Mrs C L, aged 66 years Ophthalmometric measurement March 10, 1894, as follows

R E, ax 110°, amount corneal astigmatism 6 D, corneal radius 8 5 m m, ax 20°, amount corneal astigmatism 6 D, corneal radius 7 5 m m

Graefe extraction with iridectomy June 1, 1894 Measurements taken June 22, 1894

R E, ax 95°, amount corneal astigmatism 9 D, corneal radius 7 4⅔ m m, ax 10° amount corneal astigmatism 9 D, corneal radius 8 7¼ m m

Taken again April 26, 1895 Astigmatism much reduced

R E, ax 95°, amount corneal astigmatism 3 D, corneal radius 7 9⅔ m m, ax 20°, amount corneal astigmatism 3 D, corneal radius 8 3¾ m m

Case 5 —Illustrates the influence exerted on the corneal curves as well as the changes occasioned by its removal Mr P M, aged 50 years Pterygium L E, extending 2½ m m over cornea toward the pole from inner side

Ophthalmometer showed the following

L E ax 80°, amount corneal astigmatism 2½ D irregular, corneal radius 8 9⅛ m m, ax 170° amount corneal astigmatism 2½ D irregular corneal radius 8 3⅓ m m

Pterygium removed Feb 12, 1894 Reëxamined April 17, 1894, with the following result L E, ax 90°, amount corneal curvature 2 — D irregular, corneal radius 8 7½ m m, ax 180°, amount corneal curvature 2 — D irregular, corneal radius 8 3 m m

Cases 6 and 7 —Illustrating the change in corneal curvature accompanying glaucoma Case 6, Mrs W C W, aged 45 years Ophthalmometric measurements many, usually with a result such as observed Feb 10, 1893, which was as follows

R E, ax 90°, amount corneal astigmatism ¼ D, corneal radius 8 1½ m m, ax 180°, amount corneal astigmatism ¼ D, corneal radius 8 1+ m m

L E, ax 90°, amount corneal astigmatism ⅓ D, corneal radius 8 1½ m m, ax 180°, amount corneal astigmatism ¼ D, corneal radius 8 1 m m

Feb 28, 1893, she came with glaucomatous symptoms beginning with iritis, sluggish congested background with pulsation The measurements were as follows

R E ax 90° amount corneal astigmatism ⅓ D corneal radius 8 0½ m m, ax 180°, amount corneal astigmatism ⅓ D corneal radius 8 1 m m

L E, ax 90°, amount corneal astigmatism ¼ D corneal radius 8 0½ m m, ax 180°, amount corneal astigmatism ¼ D corneal radius 8 1 — m m

This attack was recovered from, but on Sept 5, 1893, she came to me with a yet more marked series of symptoms when the measurements were as follows

R E ax 90°, amount corneal astigmatism ½ + D, corneal radius 8 0 m m, ax 180° amount corneal astigmatism ½ + D corneal radius 8 + m m

L E ax 95° amount corneal astigmatism ¾ — D, corneal radius 8 0 m m, ax 180° amount corneal astigmatism ¾ — D corneal radius 8 1½ m m

When this attack was recovered from she resumed her normal measurements

Case 7 —Mr A G, aged 82 years Came to me during the

opening of a glaucomatous attack Jan. 30, 1894, when the measurement was as follows:

L. E. ax. 85, amount corneal astigmatism ½ D., corneal radius 7.6[illegible] mm.

L. E. ax. 175, amount corneal astigmatism ½ D., corneal radius 7.5 mm.

The disease progressed rapidly; an operation was refused and the sight destroyed. The measurement taken March 30, 1894, was as follows:

L. E. ax. 80, amount corneal astigmatism 1 D., corneal radius 7.[illegible] mm.; ax. 175, amount corneal astigmatism 1 D., corneal radius 7.[illegible] mm.

By May 1, 1895, had increased as follows:

L. E. [illegible], amount corneal astigmatism 10 D., corneal radius 7.[illegible] mm.; [illegible]5, amount corneal astigmatism 10 D., corneal radius 8.0 mm.

Case [illegible].—Illustrating change in corneal curvature occurring in [illegible] of [illegible]. Miss M. B., aged 23 years. Examined at the first suggestion of the disease showed the following measurements Feb. 1, 1894:

R. E. ax. 8[illegible], amount corneal astigmatism [illegible], corneal radius 7.6[illegible] mm.; ax. 170, amount corneal astigmatism [illegible], corneal radius 7.5 mm.

L. E. ax. 6[illegible], amount corneal astigmatism [illegible], corneal radius 7.[illegible] mm.; ax. [illegible], amount corneal astigmatism [illegible], corneal radius 7.[illegible] mm.

Examined after its rapid development, April 7, 1895:

L. E. ax. [illegible], amount corneal astigmatism [illegible] D., corneal radius 7.[illegible] mm.; ax. 170, amount corneal astigmatism [illegible] D., corneal radius 7.6[illegible] mm.

L. E. ax. 95, amount corneal astigmatism [illegible] D., corneal radius 7.[illegible] mm.; ax. 180, amount corneal astigmatism [illegible] D., corneal radius 7.[illegible] mm.

SPINE BRACE

BY A. E. HOADLEY, M.D.

[illegible] Surgery and Surgical Diseases of Joints and [illegible] in the College of Physicians and Surgeons; [illegible] Surgery and Diseases of Joints, Chicago Policlinic.

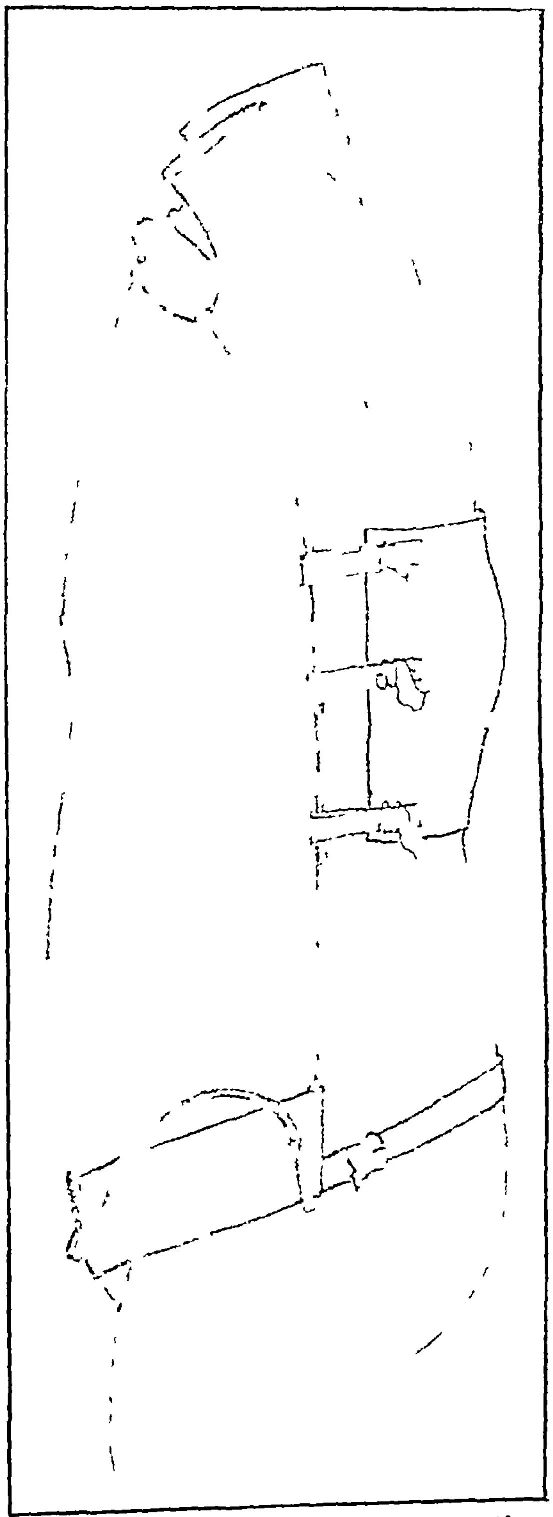
CHICAGO.

The brace that I wish to describe and exhibit, is one that I have designed and adopted for mechanical support of the middle region of the spine, the range of its greatest utility being the support of the spinal column between the middle of the lumbar and the middle of the dorsal regions, although its usefulness is not strictly confined to these limits. Inasmuch as the greater number of diseases of the spinal column requiring mechanical fixation occur within this region, its usefulness will be comparatively great if found to be an efficient brace.

In its simplest form the brace consists of a steel frame, a rigid chest pad and two aprons. The chest pad is adjusted in contour to fit the upper anterior portion of the chest. The pad should be in length about three times its width and adjusted transversely, resting immediately below the sterno-clavicular articulations. Its real length transversely should be as long as practical without being interfered with by the action of the pectoralis major muscles, in the movement of the shoulder. It should be made of sheet metal hammered to give shape and rigidity, covered and lightly padded.

The frame consists of one piece of light round rod steel, from three-sixteenths to five-sixteenths of an inch in diameter, so shaped that it crosses the body above and below and lies parallel with, and in close proximity to each side on a line with the axilla; the ends are welded or brazed where they meet, making it one continuous piece.

To facilitate the description of the frame we will divide it into four portions—an upper, a lower and two lateral portions. The upper and lower cross in front of the chest and pelvis respectively, and no portion of the frame passes behind the body. The upper portion of the frame arches upward and forward from a short distance below the axillary space on one side, crosses the chest pad, and then downward and backward to a corresponding point on the opposite side, where it becomes continuous with the lateral portions. There is no fixed point to indicate where the upper and lateral portions come together; a gentle reverse curve marks the place. The lateral portions are so adjusted as to lie close to the sides, a little nearer the posterior than the anterior aspects, and extend from below the axilla to the space just behind the anterior superior spine of the ilium, below the crest and above the trochanter major. In children, this portion is practically straight, while in adult females they bend in at the waist line and then arch out over the more or less prominent hips, but remain straight in the antero-posterior directions unless some deformity requires a change in this shape.



The lower portion is simply to connect the two lateral portions across the body at their lower ends and hold them rigid relative to each other In the adjustment of this portion, however, there are some difficulties, for if we extend it straight across from the lower end of one lateral portion to the other, it would prevent the flexion of the thighs, and then again if we arch it up over the thighs it would cross the body above the umbilicus and very materially interfere with the clothing at the waist And to cross behind the body would be still more objectionable, as the patient would then have to lie upon it and it would be more difficult to put it on and take it off, so it must take a somewhat tortuous course and cross in front, by avoiding those places where its presence would be objectionable This is accomplished by having the lower portion turn sharply upon the lateral portion which it is to follow a short distance and then arch in over the flexed thigh and then depress to, or very near the pubis, to some extent, following the fold of the groin in the direction of Poupart's ligament and as close as possible, having in mind that when the finished brace is applied no part of the frame touches the body but lies very close to it at all points

The upper portion of the frame rests by its central portion upon the center of the chest pad, to which it is secured by a double acting joint so that the pad may adjust itself to the chest

The lower portion of the frame is prevented from touching the body and given a fixed point by an apron made of two thicknesses of canvas from two to four inches wide, according to the size of the brace, between the layers of which a few whalebones have been inserted vertically to prevent rolling The apron is secured to the lower extremities of the lateral portions of the frame by its ends, and at such an angle that its direction from its attachment toward the center shall be downward, or, in other words, the upper margin of the apron at its attachment shall be the longer one, otherwise the tendency will be for the apron to slide up across the center of the abdomen This apron should be just long enough to keep the lower part of the frame from touching the body If properly adjusted it will pass across the lower part of the abdomen very close to the pubis, and upon each side will include, and remain below, the anterior superior iliac spines which constitute the lower fixed point of the frame

To complete the brace of simple form it is only necessary to attach the second apron or back band This second apron, which is to extend from one lateral portion of the frame across the back to the other, is to be also of double thickness made in shape to fit any angular deformity It should be from three to six inches wide without whalebones One end is to be permanently fastened to one lateral portion of the frame, at a position opposite that portion of the spine to be supported, the other end is to be provided with two or three straps with buckles with which to buckle it to the opposite lateral portion of the frame Thus completed, we have a spine brace of the simplest possible construction, the smallest amount of material, and at the same time providing for the fixation of the three points relative to each other, in a most positive and efficient manner The upper front part of the chest, the pelvic bones below and the weaker portion of the spine behind are retained in relative position to each other with positive certainty Positive, because these are parts of the framework of the body that have a certain relative stability to each other, and between which all of the deformities in caries of the spine in this region occur These are the points, and the only points, where definite and reliable resistance to deformity can with certainty be applied and maintained

In regard to the mechanical adaptability of the different parts to the purpose for which they are designed, I will speak separately

The frame as just described is identical with the first one that I made three years ago While I have experimented considerably, I have not in any respect changed the design originally made for the plain brace All that I can say of it is favorable, there are comparatively no objectionable features, while there are a few that are highly commendatory It is very light, strong, rigid, simple of construction, easily changed in shape, composed of one piece, and it is as much out of the way as it is possible to have anything that can claim the name, spine brace It can be readily constructed by any common blacksmith at the cross roads, which is no small consideration from an economical point of view

The small canvas apron that crosses the pelvis shrinks and molds itself over and around the anterior spines so that a most satisfactory support for the lower end of the brace is secured, capable of resisting any force that may be required either continuous or intermittent, and without producing excoriations or large callosities The difference between the plump or flat abdomen in the adjustment of the lower fixation is of no importance, even with the very fat there is less to contend with this, than with any other of the forms of lower fixation with which I am acquainted This small apron, so called, which is little more than a strap, is all that can be required and comparatively speaking it is *multum in parvo*

It is now about six years since I adopted the chest pad to support the upper part of the column Why it had not been used, fairly and squarely before, I did not know I could neither find that it had been used simply and alone, nor any reason why it had not been To me it seemed perfectly feasible, and from an anatomic standpoint, eminently proper I therefore determined to try it and, if possible, find out why it was in all corrective and retentive appliances for Pott's disease, that this particular region, the center and upper part of the chest, was universally avoided

I began by using a small pad to which I secured the upper ends of the parallel uprights that support the back pads of the common form of brace I found that the small pad was sufficient and comfortable, and as far as I could observe there were no ill effects from its use Consequently, when I came to design the present brace, the chest pad was no experiment It had already, in my hands, proved to be efficient and satisfactory I have now used it on this brace for nearly three years, and in a great variety of cases old and young, and in no single instance have I been able to observe the slightest deleterious consequences There is no complaint whatever, and no local changes to be seen I am, therefore, most emphatically of opinion that the proper place to secure and adjust the upper anterior fixation in spine brace is the upper part of the chest when the disease is low enough to permit I do not believe that there is any tendency to flatten or distort the contour of the chest, even the active rachitic patient tolerates this pressure without the slightest local change Neither is there the slightest impediment to respiration Relatively, the chest is the proper place, as suitable leverage can be obtained there and anatomically it is rigid and the effect of counter pressure is direct and reliable through the bony framework to the diseased portion and entirely independent of any muscular action whatever, and clinical experience thus far, shows that any required degree of pressure is tolerated with comfort, leaving perfect freedom of movement to the shoulders a condition of things quite unusual in spine braces

The back band that crosses the back at the seat of the disease, from one lateral portion of the frame to the other, furnishes, in my opinion, the best possible retentive force The distribution of pressure over a large surface is an advantage It is tolerated with perfect comfort It does not induce pressure atrophy or excoriate Pressing as it does, firmly upon the angles of the ribs as well as upon the spines, its influence to prevent or correct rotation or lateral deviation is far more than would at first sight be appreciated and when combined with some of the accessories which are to be described, this particular resistance to rotation and lateral curve or deviation becomes most effectual The firm unyielding character of the support and the great degree of force in the direction of correction that can with comfort be tolerated is surprising With a firm adjustment of this brace, bringing proper tension upon the gently curving chest pad, and bringing the pelvic strap or apron securely against the iliac spines and with the firm application of the back band to the full width of the back, exerting pressure upon the ribs as well as the spines, there is no tendency whatever, in the average cases, for any body movements to take place, such as the rotation of the upper part upon the lower, deviating to one side or the other The support is practically perfect, maintaining equal poise and suspending all voluntary effort to sustain equilibrium and the erect attitude

The foregoing description of the brace, together with the description of its applicability, refers only to the brace in its simplest form and to diseased conditions of average severity with but moderate deformity

The brace, however, is susceptible of many modifications and the addition of many accessories to meet the requirements of varying diseases and deformities, without losing the original principles of construction

The most simple modification which changes the shape of the frame is the substitution of a pad over the pubis and lower end of the rectus muscle, similar in construction to the chest pad, to take the place of the canvas apron at that point The frame is then changed so that the side portions, just above the crest of the ilium, turn forward and inward, to follow nearly the fold of the groin, and to meet in the center over the pubic pad, and to which it is attached by means of a joint that will permit of a racking motion only, two staples, an inch or two apart, answer very well This modification of the frame does away with that portion that passes down to the space above the great trochanter This simple form is all that can be desired as a convalescent brace It is light, easy, inexpensive and very efficient, and the pubis and tissues immediately above it tolerate the pad pressure remarkably well

When it is desirable to fit this brace to a patient who has a tendency to a lateral inclination it should be provided with three pads, one above and one below on the concave side and the other in the middle of the convex side The one below should be round and hung loosely on the lower end of the frame, so as to rest in and adjust itself to the space described above the great trochanter The upper pad should rest just as close to the axilla as practical, the frame to be modified so as to support it It may be arranged transversely or vertically I usually use at this point, long or oblong pads The middle pad should be long and attached, with its long axis vertical to the lateral portion of the frame at the place where the pressure is to be exerted

As much retentive and corrective force may be applied in this way as the patient can tolerate Where great need exists for lateral retentive force, it is advisable to add crutches to the brace The crutches can be made a part of the frame, and adjusted from below by raising or lowering the entire frame, which can be done within short limits, or, what is better, have the crutches supported by a separate piece made adjustable upon the lateral portion of the frame Where this lateral method is adopted it is necessary to have the back band secured by straps and buckles upon each side Where the crutches are added it is also necessary to attach a supporting band at the lower end of the frame to carry the crutches and their superimposed weight A strong webbing strap, buckled across the lower part of the back or sacrum from the lower extremity of one lateral portion of the frame to the other, answers this purpose exceedingly well

Any required degree of support is easy to bear and is unyielding It is by far the best crutch support with which I am acquainted Taken together with the little pelvic apron that crosses in front it embodies the principle which is in the support adopted by the color bearer, in carrying the heavy pole and flag Pads at the lower extremities of the lateral portions of the frame are advisable where the supporting strap is applied, although not strictly necessary where the frame is well made and rigid

Where there is much compensatory lordosis, protrusion of the lower ribs, or a very prominent abdomen, an apron of proper dimensions should be strapped across the front of the abdomen at the place required and with the required tension Occasionally it is desirable to include the whole front of the body in such an apron In some cases where the body is thin and the spines prominent at the seat of the disease and deformity, it is advisable to provide the back band with two pads, to rest one upon each side of the spine These pads should be secured to the back band, made wide enough to extend from the spines of the vertebræ to the angle of the ribs and as long as the band is wide They should be made as hard and as smooth as practical by stuffing them with cotton or wool, or make them primarily of folded blanket

To make the frame for any given case it is always advisable to first make a frame of soft iron, or copper wire, of a size that can be readily bent with the fingers, should be selected The patient should be placed lying on the back, with the body in the position in which it is to be retained, and the wire bent to fit the body just as the finished frame should fit It is best to adjust the wire across the lower part of the body first, and the ends will lap across the top of the chest where the lapped ends are to be secured by winding them around each other, or winding with a string, the former is the best plan This wire frame which can be made exact in shape, furnishes the artisan perfect lines for the construction of the finished steel brace

WHEN SHALL HYSTERECTOMY BE PERFORMED IN PUERPERAL SEPSIS?

Read at the Mississippi Valley Medical Association at Detroit Sept 3 1895

BY BAYARD HOLMES, B S , M D

PROFESSOR OF THE PRINCIPLES OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO

CHICAGO

It must be admitted by all observers that too many women die of puerperal fever, even in these antiseptic and aseptic times Curetting and irrigation with all their modifications are not always effective Infection gets beyond the reach of the curette The interior of the uterus becomes clean and relatively well, but the sepsis goes on In the treatment of infected wounds, one of the first indications is the removal of the infected tissues Hysterectomy alone in certain cases of puerperal sepsis meets this indication It is the purpose of this paper to show when hysterectomy should be undertaken for this disease Incidentally the frequency of the disease and some points in its pathology are treated

I —FOUR CASES OF PUERPERAL SEPSIS TREATED BY THE AUTHOR BY FOUR DIFFERENT METHODS

Case 1 —Curetting and Irrigation only—Death —The patient was a multipara 26 years old She came from an Irish family and had had tubercular disease when a child She was confined in a barn by a competent physician with no other person about to help him There was violent post-partum hemorrhage which yielded to nothing, except the introduction of the hand into the uterus and slow removal of the placenta This operation was done without help and without chloroform Sepsis appeared almost at once The uterus was carefully curetted several times and irrigated at frequent intervals In spite of everything the sepsis continued for seven weeks and the patient died of pulmonary infarction at the end of that time

Case 2 —Septic Peritonitis—Double Salpingectomy—Death —This patient had a history of gonorrhea after the birth of her first child She was 35 years old and had suffered frequent attacks of ' pelvic inflammation " She had a second child three years ago, the birth of which was followed by sepsis She was confined to her bed three months She had an abortion performed on a three months fetus four weeks ago This had been followed by a pronounced sepsis The uterus had been curetted carefully by a competent physician and twice packed with iodoform gauze for six hours each time On examination, March 10, 1895, I found her temperature 104 6 The pulse was 140 The respirations were rapid and constrained The abdomen was tympanitic Vomiting had been almost constant for three hours The bowels had resisted all attempts to move them A large area of dullness could be made out in the right inguinal region The uterus was tipped over to the left The right pelvis was filled with a doughy mass The extremities were cold Under these circumstances not much could be expected from operation, yet nothing could be gained by other treatment The abdomen was therefore opened The right pelvis was found to be a great abscess in which the greatly distended and infiltrated tube was found The left tube was also full of fluid (old pyosalpinx) and was removed The uterus was almost exactly the normal size It was not edematous and was left in the pelvis Both sides of the pelvis were drained with gauze tampons through the abdominal wound The patient rallied well after the operation and did well for five days She gradually grew worse then, had several attacks of phlebitis and died of pulmonary embolism nine days after the operation There were no symptoms of peritonitis after the operation

Case 3 —Curetting—Removal of Right Tube and Ovary—Vaginal and Abdominal Drainage—Death without Peritonitis —This patient was 30 years old She had been confined five weeks before examination Symptoms of sepsis appeared on the fourth day and continued of a low grade There was a renewal of septic symptoms on the tenth day after sitting up and walking a little When I examined her, April 20, 1895, she was slightly tympanitic, the pulse was 112 and the temperature 101 She had no appetite and had vomited a little once or twice The bowels were easily moved with enemas and mild laxatives The vagina was edematous but the uterus was well contracted The right side of the pelvis, as felt through vagina, was firm and hard, the left side somewhat less so The patient was carefully watched for three days while the uterus was almost constantly irrigated and twice curetted, and packed with iodoform gauze All the symptoms grew steadily worse, chills occurred twice a day with a slow rise of temperature and tympanitis This led me to make abdominal section The right tube was found as large as the thumb red and infiltrated It was removed with the right ovary The uterus was firm, hard, small and not at all edematous I did not remove it The left tube was normal and was not disturbed The right pelvis was drained by means of a tube from the abdominal wound above into the right side of the vagina and packed about with iodoform gauze *After a few days of improvement the* patient grew gradually worse and died of septic phlebitis *without peritonitis* eight days after the operation

Case 4 —Septic Peritonitis—Removal of both Tubes and Ovaries and the Uterus —The patient was a multipara 32 years old The labor occurred six weeks ago and was uncomplicated A midwife, noted for her train of puerperal fever, was in attendance at the time On examination, May 14, 1895, I found a temperature of 104 degrees and a pulse of 124 The abdomen was tympanitic and greatly distended, vomiting was almost constant There was great tenderness over the whole abdomen When the patient was on her back both flanks were dull, when turned on her side, the left flank became tympanitic In making a vaginal and bimanual examination extensive infiltration of the right side of the pelvis could be made out The uterus was about the size of a uterus when four months pregnant Operation was undertaken for the removal of the septic material twelve hours later After the proper preparation of the patient, she was chloroformed and placed in the Trendelenburg position, and the abdomen opened. On the first incision, about a pint of sero-purulent fluid slowly poured out As the right tube was grasped, another gush of pus came out This broad ligament was large and edematous It was separated from its adhesions to the pelvic wall and tied off The uterine artery was ligated and the uterus was then amputated from before backward, and from right to left with a dull knife After ligating the other uterine artery and the left ovarian artery the cervix was closed upon itself by two rows of catgut sutures , one buried in the cervical tissues and one superficial in the peritoneum All hemorrhage was stopped, the abdomen carefully washed out with several pitchers of sterilized hot water and the pelvis drained with a large iodoform gauze drain coming out at the lower part of the abdominal wound The rest of the abdominal wound was closed with two rows of sutures In spite of the fact that this operation was done in a hovel, and in spite of the additional fact that a factory next door burned down three days after the operation, making it necessary to lay the patient for an hour on the sidewalk in front of the house, she made a most excellent and rapid recovery and was out of bed in five weeks

The pathology of this case is extremely interesting The section of the uterus measured 4 5 centimeters in anterior posterior diameter after hardening in formalin The transverse diameter just below the opening of the tubes, was 7 75 centimeters The diameter of a section of the ovarian ligament was 2 5 centimeters on the right side and a little less on the left side There was an abscess in the right ovarian ligament with partial necrosis of its posterior wall This abscess was about a centimeter in diameter There were two other abscesses about the same size in other parts of the ligament On inspection of a thin transverse section the interior of the uterus was found lined with a black necrotic mass Pigmentation extended outward from the mucosa about a centimeter in all directions The whole of the right broad ligament was of this same dark color On microscopic

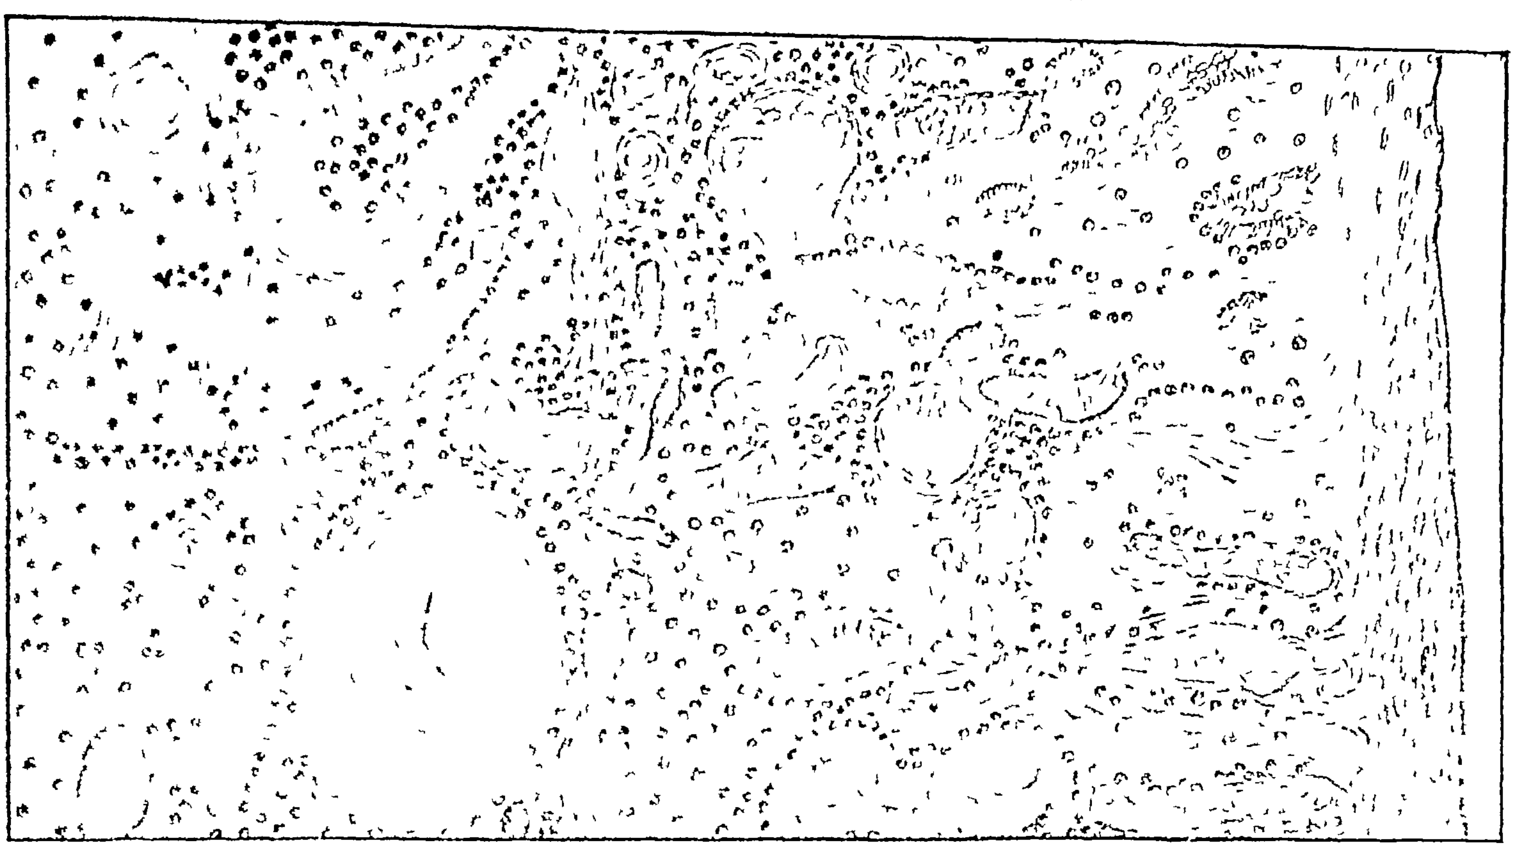

FIG. 1—[illegible] section of the body of the uterus partially schematic p the peritoneal surface a, a, a, obliterated blood [illegible] filled with pus corpuscles (c) and leucocytes m, m, mastzellen The other end of the section [illegible] The mucosa was everywhere surrounded by groups of pus corpuscles

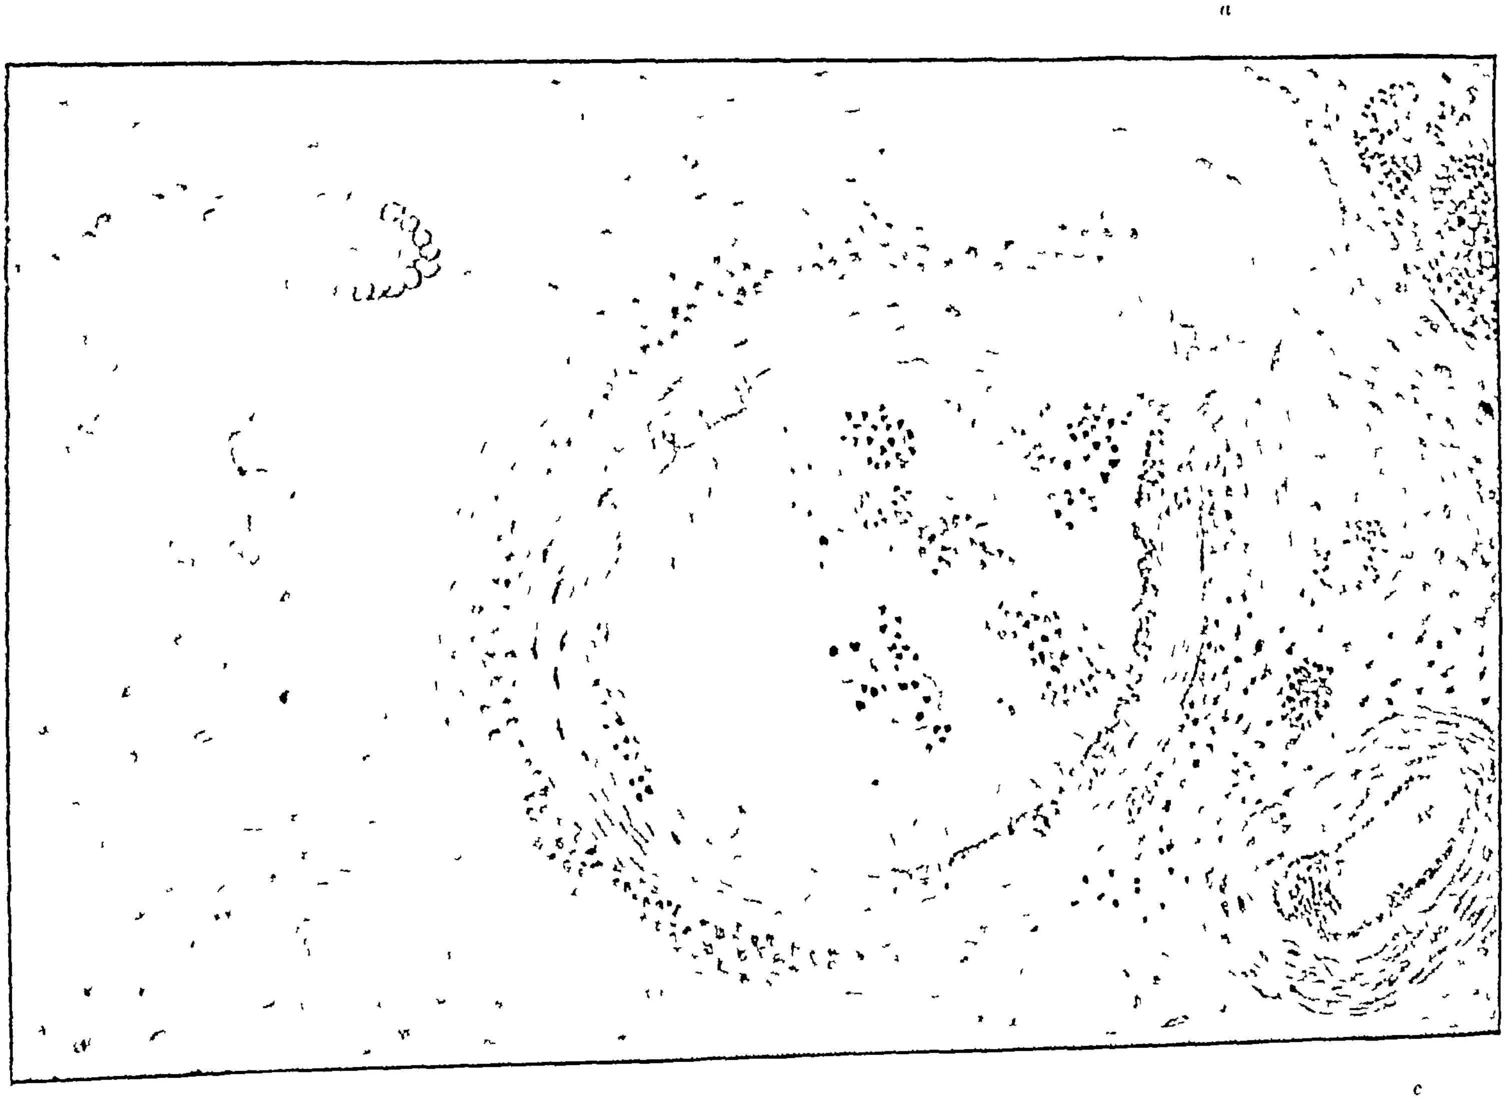

FIG 2—Section of the right broad ligament showing an advancing thrombus in an artery coming out from an obliterating thrombus in a branch, (a) marked perivascular infiltration (b) and complete thrombosis of accompanying vein (c)

examination the mucosa was found in a condition of rapid reproduction In many places, as shown in the drawing, repair was nearly complete Yet everywhere the epithelial cells and mucous glands were surrounded with groups of pus cells The perivascular lymph spaces in the musculosa from the mucosa outward were in many places crowded with pus corpuscles, but in no place was an abscess of any size found *Mastzellen* were very abundant in some parts of the musculosa, but not very often found where the pus corpuscles were most numerous Many of the blood vessels of the uterus were entirely obliterated with thrombi and these thrombi were sometimes crowded with pus corpuscles In one section of the broad ligament a small blood vessel was found partially occluded by a thrombus which had gone out from a small branch of the artery The drawing shows the condition very well The obliterating thrombus in the branch is full of pus corpuscles The advancing thrombus in the trunk has many such pus corpuscles between the intima and the thrombus The wall of this artery is invaded on one side Some such blood vessels were entirely obliterated Many sections of the tube on both sides showed no accumulations in the tubes, no destruction of the *arbor vitæ* of the tube and no considerable inflammation of the peritubal tissues

The condition may be described as a suppurative endometritis, suppurative perivascular lymphangitis of the uterus, of the ovarian ligaments and of the broad ligament Obliterating thrombosis of uterine and peri-uterine blood vessels Multiple abscess of the right ovarian ligament Multiple peri uterine peritoneal abscesses, adhesive and limiting peritonitis

II —THE RESULTS OF CURETTING IN THE HANDS OF ITS ADVOCATES

Leopold (*Dritter Beitrag zur Verhutung des Kindbettfiebers*) *Arch fur Gyn*, vol xxxv p 149) considers 1,369 cases of labor attended 1888 and out of these 15 died, only two of them sepsis

Braun-Firnwald (*Ueber antiseptische Excochleatio uteri bei Endometritis puerperalis Arch. fur Gyn*, vol xxxvii, p 452) made a study of 7,600 cases of labor in a period of two and half years, 1887-1889, curettement was performed in 101 of these cases Out of these 101 cases, 96 recovered and 5 died Beside these five deaths there were forty other deaths

The following tables show the causes of death

12 cases from March 1, to December 31, 1887

Placenta previa, hemorrhage	3
Rupture of the uterus	2
Suppurative nephritis and cystitis, old tuberculosis	1
Phlegmon of the foot, pyemia	1
Eclampsia	1
Pericervical abscess	1
Puerperal sepsis	3
	—12

During the year 1888 diffuse peritonitis from rupture of the gall bladder during labor	1
Rupture of cervix uteri	3
Osteomalacia, Cæsarean section, degeneration of liver and kidneys without asepsis	1
Apoplexy, Cæsarean section, living child	1
Eclampsia, (1 hemorrhage nephritis)	5
Osteomalacia, Cæsarean section, sepsis	1
Rachitis, Cæsarean section, sepsis	1
Puerperal sepsis	8
	—21

Jan 1 to Sept 30, 1889 Placenta previa, hemorrhage	1
Rupture of the uterus	2
Chronic nephritis	1
Puerperal sepsis	3
	— 7

Total deaths	40
Puerperal sepsis	14
Per cent of deaths from sepsis of all deaths	35

It appears that puerperal sepsis was the greatest cause of death even in the hands of a careful obstetrician The curetting of the uterus was not an unfailing remedy, as the following epitome of the histories of the five cases that died after curetting shows

1 Normal labor, slow infection on fourth day Curetting Peritonitis on eighteenth day Temperature 40 degrees, vomiting delirium Death on thirtieth day

Autopsy mild puerperal endometritis uterine lymphangitis, general purulent peritonitis, hemorrhagic left pleuritis Observations Hysterectomy ought to have been performed on the eighteenth day

2 Normal labor Chill and rapid infection on the fifth day Intra-uterine irrigation without effect Curetting on the eighth day, no avail Sudden onset of vomiting and distension, thready pulse Death on the tenth day

Autopsy slight endometritis, double salpingitis general suppurative peritonitis with large exudate Observations Hysterectomy ought to have been performed on the eighth day

3 Normal labor Fever on the second day Bad smelling lochia Curetting on fourth day with removal of decidua no avail On the twelfth day distension, vomiting Death on the seventeenth day

Autopsy endometritis, uterine phlebitis, diffuse suppurative peritonitis Observations Hysterectomy ought to have been performed on the thirteenth day

4 Normal labor Chill on the morning of the fifth day Temperature 39.2 degrees Intra uterine irrigation, no avail, diarrhea On the ninth day, curetting, no avail On the thirteenth, symptoms of phlebitis Death on the twenty-first day

Autopsy slight endometritis, general peritonitis Observations Hysterectomy ought to have been performed on the eighth day

5 Normal labor On the fifth day slow infection On the sixth, temperature 39 degrees Curetting, normal temperature the two following days On twelfth day chill, temperature 40 degrees, fresh blood in lochia Intra-uterine irrigation iodoform tamponade No avail On nineteenth day large hemorrhage from uterus Death on twenty-ninth day

Autopsy endometritis, subsequent septicemia, acute anemia Observations Hysterectomy ought to have been performed on the nineteenth day

In the 101 cases of sepsis in this series, the following table shows the time of onset of infection as indicated by the rise of temperature, or by the chill, and interpreted by the subsequent history

On the day of labor	1 case
1 day after labor	1 "
2 " ' "	10 "
3 " ' "	14 '
4 " " "	30 "
5 ' " "	21 "
6 " " "	11 '
7 " " "	6 "
8 " " "	3 '
10 ' " '	2 "
11 " " "	1 "
12 " " "	1 "
Total	101

We see, then, that in 101 cases of sepsis treated by Braun-Firnwald, curetting failed five times and in these five cases there is every reason to believe that hysterectomy would have been effectual in saving the life of the patient

III —PUERPERAL SEPSIS IN CHICAGO, NEW YORK, AND BROOKLYN

In the city of Chicago during the years 1881-1894 2,127 deaths from puerperal fever were reported, or about 0 9 per cent of all deaths This is computed to be about 3 5 deaths to each 1,000 births In the year 1894, 214 deaths were reported from the city of

Chicago as due to puerperal fever, while many other reports, under different heads, would indicate a still larger death rate from this cause It is estimated that more than half of all confinements in the city are in the hands of midwives[1]

The following table is copied from the report of the Department of Health of Chicago and gives in the first column the year, in the second column the number of deaths reported during that year from puerperal fever, in the third column the per cent of these deaths of the total mortality, and the fourth column the number of deaths from this cause to the 1,000 births reported

Year	No deaths reported	Per cent of deaths	No deaths per 1,000
1881	111	1 03	7 31
1882	107	0 81	5 16
1883	152	1 32	7 08
1884	108	0 86	4 57
1885	107	0 86	4 23
1886	126	0 92	4 11
1887	110	0 91	5 16
1888	186	1 18	6 10
1889	137	0 81	3 65
1890	166	1 76	3 55
1891	176	0 63	3 64
1892	171	0 66	3 13
1893	181	0 67	3 31
1894	214	0 89	3 22

In New York for the six years ending May 31, 1890, there were 250,739 deaths, of which 116,126 were females 2,276 died in the puerperal state and 1,250 of these deaths were due to puerperal fever

In Brooklyn during the same period, there were 112,367 deaths, 53,866 being females, 867 deaths were in the puerperal state and of these 462 were due to puerperal sepsis

The question of treatment of puerperal sepsis by hysterectomy is therefore one which vitally concerns at least 214 persons a year in Chicago, 208 persons a year in New York city, and 78 persons a year in Brooklyn

IV —ANALYSIS OF THE CASES OF DEATH FROM PUERPERAL SEPSIS OCCURRING IN 6,635 CONSECUTIVE CONFINEMENTS

Perhaps the relation of puerperal sepsis to the normal uninfected puerperium can be best understood by making a study of the work of some of the obstetrical hospitals under the best management For this purpose I first call your attention to the Charité, of Berlin All my information comes from the official reports in the *Charité Annalen* for the years 1889–90, 1890–91 and 1891–92, 1892–93 In these four years, 6,635 women were confined, with 79 deaths from all causes Of these deaths, thirty-three resulted from puerperal sepsis In order to fully understand these cases I have made brief abstracts of the histories and the pathologic findings at post-mortem These cases were treated by Hensoldt,[3] Schwarze, Hünermann and Hochsetter, during the four successive years mentioned, each having the clinic a year at a time

During the year Hensoldt had 1,626 confinements, covering a part of the calendar years 1889–90 There were sixteen deaths that is to say a death rate of 0 61 per cent This death rate was distributed as follows puerperal fever, ten; heart failure, two, eclampsia, two, pneumonia, one, hemorrhage, one, total, sixteen

There were sixty-two cases of puerperal fever during the year 1890–91 Some cases were insignificant Among these were three cases of unknown origin, two cases of puerperal endocarditis, two cases of mild phlegmasia alba dolens, eleven cases of parametritis, three cases of diphtheria of the external genitals, one case of inflammation of the sacro-iliac joint, and one case of tuberculosis of the lung In fourteen cases the gonorrheal condition of the flow was demonstrated In one of these cases puerperal fever followed labor One ovarian tumor was present in a secundipara Syphilis was present in 63 cases out of the 1,626, but we are not told how many of these were included in the 62 cases of sepsis

The total number of infected cases among these 1,626 confinements was 62, being 3 81 per cent This compares very favorably with the records of the hospital during the previous years In the twelve months preceding, the hospital year 1888–89, the per cent of infected cases was 2 31 In the year 1887–88 the rate of infection was 2 50 per cent, and in the year 1886–87 it was 2 31 The number of deaths from infection during these four terms of twelve months each was 61 per cent, 36 per cent, 37 per cent and 55 per cent respectively Nine of the ten cases that died under Hensoldt's care I have carefully abstracted and added a line of observations They are as follows

1 Normal birth, chill on fifth day, scarlet fever-like eruption over whole body, marked gastric symptoms, stinking lochia urine free from albumin The eruption disappeared on the tenth day, but the fever continued and a slight systolic murmur appeared with mild bronchitis The spleen became enlarged and the abdomen distended On the fourteenth day, emboli under the skin showed themselves, and on the fifteenth day collapse and death

Autopsy gangrene of the skin of the right index finger. multiple infarcts of the left arm, fatty degeneration of the heart muscle mitral stenosis, mitral endocarditis, edema and red hepatization of the lungs, hyperplasia and infarcts of the spleen, nephritis, hepatitis Observations This case could probably have been saved by hysterectomy performed on the tenth day or before the fourteenth

2 Normal birth, chill on the third day, systolic murmur on the eighteenth day, delirium on the twenty-first day with symptoms of compression of the brain, exophthalmus on the twenty-third day, death on the twenty-fourth day

Autopsy purulent meningitis of the base, endocarditis and pericarditis, dilatation and hypertrophy of the heart, right circumscribed pleuro-pneumonia, edema of the lungs, slight parenchymatous nephritis, metritis, endometritis, pyelitis, cystitis Observations This case might have been saved by hysterectomy performed on or before the eighteenth day

3 Normal second birth, chills on the third day, bad smelling lochia, peritonitis on the fourth day, death on the seventh day

Autopsy general fibrinous peritonitis, diphtheritic endometritis, phlegmonous parametritis, pulmonary edema, parenchymatous myocarditis, parenchymatous hepatitis, hyperplasia of the spleen Observations This case could probably have been saved by hysterectomy performed on the fourth or on the fifth day

4 Normal third birth, on the third day stinking lochia and high fever, evidence of tuberculosis in apices of both lungs, on the tenth day a venous thrombus on the inner side of the right knee, on the twelfth day this thrombus was opened and discharged pus, dyspnea this day with bloody expectoration, on the fourteenth day somnolence, thin brownish sputa, right pleuritis, on the sixteenth day sudden death in collapse

Autopsy endometritis, pericarditis pleuritis, parenchymatous nephritis, hepatitis, splenitis, old phthisis, suppurative right pneumonia Observations This case could perhaps have been saved by hysterectomy performed on the tenth day with coincident removal of the thrombus in the leg

5 Primipara 19 years old, normal labor, followed by rapid pulse, 92–120, membrane appearing on the vagina on the

---

[1] Report of Commissioner of Health, 1885, pp 263

[2] Billings, John S Vital statistics of New York city and Brooklyn U S Department of the Interior Washington,1894 4°

[3] Hensoldt Charité Annalen, sixteenth year, 1891, p, 256, et seq

third day, on the sixth day high fever with foul lochia, pain on the right side of the uterus, on the eleventh day chill, high fever and severe general symptoms, on the fourteenth day vomiting, with abdominal pain and distension, on the fifteenth day continued vomiting, increased tympany, diffuse bronchitis, very small and rapid pulse and rapid respirations, on the twentieth day the left shoulder became swollen and painful, respiration more rapid, right sided pleuritis, on the twenty first day emboli were observed under the skin of the back and beginning bed sores, death on the twenty-sixth day

Autopsy puerperal fever, endometritis diphtheritica placentaris, adhesive and encapsulated suppurative peritonitis, general fibrinous, purulent and ichorous peritonitis, hyperplasia of the liver, endarteritis of the aorta, edema of the lungs Observations Hysterectomy was indicated on the fourteenth day It is uncertain what the membrane was If diphtheria, it is a question to be studied

6 The eighth birth of a woman 45 years old Repeated attempts had been made by two physicians to apply the forceps before admission to the hospital The high operation was performed and a large child (58 c m long, 5320 g weight) easily delivered The placenta was removed on account of hemorrhage and atony of uterus The patient vomited almost continually, the pulse was very rapid (116–124) the temperature high and the lochia offensive On the eighth day irrigation of the uterus and a second tamponade of uterus, the seventh day after this there was a chill, the temperature rose and the lochia continued offensive The uterus did not contract On the fourteenth day painful dyspnea, diffuse bronchitis, small pulse (108–120) frothy expectoration Death on the nineteenth day

Autopsy puerperal sepsis, diphtheritic endometritis, parenchymatous myocarditis, fatty degeneration of the myocardium, edema of the lungs Observation Hysterectomy was indicated on the tenth or eleventh day and would doubtless have been effective in saving the life of the patient

7 Primipara, 31 years old Placenta previa, hemorrhage and delivery of a dead child in the tenth month (51 c m long, 2680 g wt), on the third day rise of temperature, on the fifth a chill and all the ordinary symptoms, on the eighth day delirium, collapse, and on the tenth day death

Autopsy diphtheritic placental endometritis, nephritis, hepatitis, parenchymatous gastro-adenitis, hyperplasia of the spleen, multiple suppurative and lobular pneumonia, hypertrophy of the heart, fatty degeneration of the myocardium, chronic endocarditis Observation Hysterectomy was indicated on the eighth day and would probably have been effective in saving the life of the patient

8 Placenta previa Last menstruation in October, 1889 Jan 25, 1890, to end of March repeated hemorrhages, treated the latter part of the time with vaginal tamponade On March 27 she entered the hospital in extreme anemia Temperature 38 5, rapid pulse The cervix admitted one finger The fundus stood at the umbilicus Labor pains Antiseptic tamponade of the cervix Anesthesia after four hours and removal of the macerated fetus and succenturate placenta Curettement of uterus On the next day temperature 40 and over, pulse 149, vomiting, on the second day delirium The lochia was not offensive On the fourth day hyperesthesia with full temperature and considerable rise of pulse rate Death on fifth day Autopsy Puerperal sepsis, diphtheritic endometritis of the cervix, beginning right hypostatic pneumonia, edema of the lungs, hyperplasia of the spleen, parenchymatous nephritis Observation This is a case of rapid infection Hysterectomy might have saved the patient if performed on the second or third day

9 Primipara, 21 years old, delivered of a small child (42 5 c m, 1670 g) with the forceps The patient was frail and anemic but had a perfectly normal course until the eighth day On the ninth day there appeared with severe constitutional symptoms a temperature of 39 9 and a pulse of 132 The slightly bloody lochia became offensive After irrigation of the uterus the temperature fell on the eleventh day to normal but the pulse remained at 100 On the fourteenth day the lochia again became offensive A second irrigation of the uterus showed no coagula in the cavity, but as the catheter was being withdrawn the patient went with a sudden spasmodic movement into a deep collapse and died

Autopsy puerperal fever with parenchymatous changes in all the organs of the body Observation this case shows the dangers of conservative treatment even There was perhaps no time during the life of the patient that hysterectomy was indicated

During Schwarze's[4] service, 1890 91, 1,480 women were confined Of these fifteen died as follows

Puerperal fever five, eclampsia six, rupture of uterus two, heart failure one, hemorrhage one, total, fifteen

1 Second confinement, 20 years old Two days before admission, chills and fever with diarrhea Temperature 39 5, pulse 124, cyanotic countenance, dry tongue, rapid breathing, no cause in lungs Tympanitis Rapid spontaneous birth of a living child The high fever continued after the birth with all the ordinary symptoms Death in the second week, apparently of edema of the lungs

Autopsy puerperal sepsis, general ichorous peritonitis, nephritis, hepatitis, parenchymatous myocarditis, hyperemia and edema of the lungs, hypertrophy of the spleen. Observation This case of infection before labor was one in which hysterectomy was indicated and would doubtless have been effectual in saving the life

2 Primipara, 20 years old Began labor with a distended tympanitic abdomen, pulse 72, no fever Some pain over Poupart's ligament on the right side, with the use of an enema a free movement was secured Five days later labor came on and in a few hours of normal labor a poorly nourished living child was born Immediately after delivery deep collapse, pulse 160 The abdomen tympanitic, painful, shortly all the symptoms of general puerperal infection, and death on the twelfth day

Autopsy endometritis and purulent peritonitis multiple pulmonary abscesses, parenchymatous nephritis and hepatitis hyperplasia of the spleen The abdomen was full of brownish pus The abdominal and pelvic organs were adherent The appendix showed the scar of an old ulcer Observation This seems to have been a case of chronic appendicitis which was perhaps one source of infection It is uncertain from the history whether or not it was the only source If it was the only source of infection, it was a case of appendicitis complicating the puerperal state If this idea is correct, removal of the appendix was indicated

3 Primipara, 29 years old On June 17, chill and fever which subsided after a few hours On June 18, labor pains came on in the night and in a few hours a living child was born During labor no fever About one and a half hours after delivery, chill, temperature 40 8 and bilious vomiting On the morning of the second day after delivery temperature 37 9 A second chill in the afternoon with a temperature of 39 6 The disease continued until June 27 when the patient died, on the ninth day after delivery

Autopsy puerperal endometritis, phlegmonous parametritis, phlegmonous myostitis of the right arm, arthritis of the left elbow, hyperplasia of the spleen Observation This was a case of rapid infection which called for early interference It could have been treated on the third day or as late as the fifth day with good hope of recovery by the removal of the uterus and tubes The history, however, is too incomplete to form the basis of the indication as to time

4 Primipara, aged 21 years, normal birth On the fifth day fever and offensive lochia Temperature and pulse continue high and a membrane appeared in the vagina Exudation felt on both sides of the uterus On the seventeenth day all the symptoms of peritonitis and on the nineteenth day death

Autopsy purulent endometritis, purulent para uterine thrombophlebitis, perithrombotic abscesses, fibrino purulent peritonitis, subinvolution of the uterus, hyperplasia of the spleen, parenchymatous hepatitis, nephritis and gastritis, multiple pulmonary abscesses Observation There was abundant time in this case to remove the infection It should have been done probably on the eighth or tenth day

5 The ninth confinement of a woman 39 years old, normal birth Great edema of the lower extremities with large varicose veins On the fourth day chill, temperature 39, pulse 120 The lochia became offensive On the fifth day painful thrombosis of both thighs, the region of these thrombi quickly became inflamed On the *labia majora* great swelling Death on the seventh day of cyanosis and edema of the lungs The thrombi in the legs were in a gangreuous condition

Autopsy gangrenous diphtheritic endometritis, parenchymatous hepatitis, hyperemia and edema of the lungs hyperplasia of the spleen Observation This was a case of rapid infective thrombosis It was hopeless after the fifth day

6 Secundipara, placenta previa, tamponade after hemor-

---

[4] Schwarze Charité Annalen seventeenth year 1892, p 479

charge and extraction On the fifth day fever and rapid pulse On the seventh, edema of the labia extending to the rectum Diphtheritic membrane on the vagina and cervix uteri Thrombosis and phlegmonous inflammation of the back and thighs No chill, no infiltration of the parametrium Death on the tenth day

Autopsy puerperal sepsis, vaginal wounds, diphtheritic vaginitis and diphtheritic inflammation of the cervix uteri, multiple abscesses of the skin, incipient parenchymatous myocarditis, endocarditis, incipient endocarditis of the aorta multiple abscesses of the left lung and edema of the lungs fibrino purulent and ichorous left pleuritis, nephritis Observation This is a case of rapid infection Hysterectomy might have saved the patient, if performed on the second or third day

7 Primipara 21 years old Delivered of a small child ([illegible] c m 1670 g) with the forceps The patient was frail and anemic but had a perfectly normal course until the eighth day On the ninth day there appeared with severe constitutional symptoms, a temperature of 39 0 and a pulse of [illegible] The slightly bloody lochia became offensive After irrigation of the uterus the temperature fell on the eleventh day to normal but the pulse remained at 100 On the fourteenth day the lochia again became offensive A second irrigation of the uterus showed no coagula in the cavity

During Hunermann's service out of 1,860 cases in the obstetrical department of this hospital, 27 died during the year 1891-1892 eclampsia ten, placenta previa one tuberculosis of lung one vitium cordis two, puerperal sepsis thirteen total twenty-seven

Beside the thirteen deaths from puerperal fever there were one hundred and forty-four cases of fever, sixteen cases of parametritis, six cases of perimetritis, one case of diphtheria of the external genitals with endometritis, and forty one cases of severe puerperal infection, with recovery There were two cases of thrombosis of the femoral vein Tuberculosis of the lungs was observed in fifteen cases There was one case of pyonephrosis, ninety cases of syphilis, seventeen children required treatment for gonorrheal ophthalmia

1 Strongly built woman but poorly nourished Temperature on admission 39 5 Stupid labored respiration, pulse 132 to 96 Uterus three fingers above the navel In urine 1 volume of albumin Three-quarters of an hour after admission spontaneous delivery of a small 25 c m child and placenta Death eleven hours after delivery Autopsy exquisite puerperal sepsis Observation This was a case hopeless from the first

2 The eighth confinement of a 33-year-old woman Rupture of the membranes at time Three days the mother went about her work until an arm presented Dilated cervix contracted uterus Temperature 39 Cyanosis Difficult version Delivery of a slightly macerated boy (51 c m , 2950 g) Liquor amnion stinking Immediately after birth the temperature was 41 7 and the pulse 111 On the next day the typical picture of sepsis double sided pneumonia severe albuminuria tympanitis, offensive lochia, persistently high fever Death on the fifth day

Autopsy puerperal sepsis, double pneumonia, diphtheria of cervix uteri, diphtheritic endometritis and cystitis, parenchymatous nephritis Observations Hysterectomy useless, except on the day of delivery

3 Third confinement, version and extraction outside the hospital On the next day dilatation of the abdomen and on the second day temperature 38 6, pulse 96 to 124 Abdomen very tympanitic Irrigation of the uterus and discharge of clots of blood The sepsis continued without chills, temperature 40 Frequent and severe dyspnea, obstruction of the bowels and diffuse peritonitis On the twelfth day edema of the lower extremities and death on the fifty-fifth day in collapse

Autopsy slow puerperal peritonitis, purulent and fibrinous, parenchymatous hepatitis, nephritis and gastritis, interstitial abscesses of the kidney, pyonephrosis, hyperplasia of the spleen and perisplenitis, perimetritis with abscesses, acute endometritis and parenchymatous gastritis Observations In this case of slow infection there was abundant time for hysterectomy It should have been done during the second week at latest

4 Secundipara, 20 years old Spontaneous delivery of a dead child before admission to the hospital On admission temperature 38 8, pulse 120 On the second day vomiting and tympany On the third day chill Continued vomiting and tympany of abdomen Temperature 39 2, pulse 124 On the sixth day petechia over the whole body, icterus, friction sounds on the lower back part of right lung, impure heart's tone, large amount of albumin in the urine On the eighth day more icterus and death on the ninth day

Autopsy diphtheritic endometritis myocarditis, parenchymatous nephritis, hepatitis, hyperplasia of the spleen, icterus Observations Hysterectomy would have been effective doubtless on the second day but not later

5 Eighth birth, 36 years old, small child (34 c m , 840 g) Temperature on admission 39 8 The birth had taken place some hours before After-birth, which was partly in the vagina, was removed under narcosis and the uterus washed out and tamponed with iodoform gauze This was removed on the second day From the second day to the seventh day the temperature was 39 Frequent irrigation of the uterus with 2 per cent carbolic acid solution On the eighth day a chill Temperature 40 pulse 144 Murmur at heart apex Chills on the eleventh twelfth, thirteenth, fourteenth and fifteenth days, with temperature between 37 and 40, pulse rapid, unaccountable On the sixteenth day swelling of the left leg with recognizable thrombus Death on the seventeenth day

Autopsy puerperal fever, endometritis placentaris suppurative thrombo-phlebitis, syphilitic cicatrices of the kidney, varicosa endocarditis Observations This was a slow infection and offered every hope that recovery would have followed hysterectomy on the eighth day

6 A primipara, 24 years old Some days before confinement, a chill as the result of attempted abortion Spontaneous discharge of the dead fetus, (25 5 c m 340 g) Temperature 38 9 On the third day a chill, temperature 39 On the fourth day, after an irrigation of the uterus, three chills Splenic tumor, vomiting, tympanitic abdomen Pronounced peritonitis Temperature 40 until the eighth day On the ninth day no fever On the tenth death

Autopsy the site of the placenta covered with a grayish-black ichorous mass The cervix was gangrenous, with two furrows, both on the posterior lip, extending from the vagina to the body (Marks of abortion) Puerperal sepsis, general fibrinous and purulent peritonitis, endometritis placentaris, gangrene of the cervix uteri, gangrenous right oöphoritis, recent parenchymatous myocarditis and hepatitis, nephritis hyperplasia of the spleen, right adhesive pleuritis, purulent thrombo phlebitis Observations This case offered hope of recovery after hysterectomy on the fifth day or earlier The history is too incomplete to indicate the time of latest hopeful operation

7 Primipara, 25 years old Moderate laceration of the cervix, normal birth under midwife Normal course until fifth day when fever and high pulse came on and continued until the eleventh day On admission, exudation in right parametrium Twelfth and thirteenth days normal temperature On the fourteenth renewed fever, with intermission daily until the eighteenth, then a remittent high fever, pleuro-pneumonia, dyspnea, until death on twenty-sixth day No symptoms of peritonitis, no chills Autopsy puerperal fever parametritis and perimetritis, multiple and purulent, subinvolution of the uterus, double hydrothorax beginning double fibrinous pneumonia, hepatitis, nephritis, myocarditis, gastritis, right hemorrhagic pyelitis Observation This case offered great hope of recovery by hysterectomy on the seventeenth day

8 Primipara, 20 years old, normal birth of a full-sized boy (52 c m , 3,000 g) Distension of abdomen immediately after delivery An area of dullness appeared on the third day, on the right side of the uterus, as large as the hand Regular course of sepsis to the eighteenth day, when death ended it

Autopsy ichorous peritonitis, endometritis, edema of the lungs, hypertrophy and dilatation of the heart, right pleuritis and right catarrhal pneumonia, nephritis, hepatitis and splenitis Observation This case should certainly have been saved by hysterectomy on the sixth day

9 Normal birth normal until fourth day Temperature then 39 5, rapid pulse, abdominal pain, irrigation of uterus on seventh day chill, with temperature 40 Digital removal of a large piece of placenta, iodoform tamponade, frequent irrigation of the uterus, on the fifteenth day evidence in urine of nephritis, on the twentieth day pupillary hemorrhage of right eye, on the thirty-second day edema of the lower extremities, on the forty-eighth day death

Autopsy puerperal fever, parametritis with right throm-

---

5 Hünermann Charité Annalen, eighteenth year, p 515

bo phlebitis, bacterial nephritis, cerebral thrombo-phlebitis multiple Observation This case could have been saved by hysterectomy on the fifteenth day and perhaps later

10 Spontaneous birth of an average child (41 cm 1320 gr) Considerable hemorrhage, manual removal of placenta High fever during the first day On the second day infiltration of right lung, on the eighth day of the left lung Double pleuritic effusion On the tenth day peritonitis and death

Autopsy uterus bicornis Endometritis, universal purulent peritonitis, double fibrinous pleuritis, partial pulmonary atalectasis Observation It is hard to say whether or not hysterectomy would have helped this case

11 Normal birth on the third day of a child temperature 38 6, pulse 96, on the fourth day a chill, temperature 40 9 pulse 120 On the tenth day a pyemic abscess of the left thigh, many other abscesses, death on the thirty eighth day

Autopsy puerperal sepsis, pulmonary edema, multiple phlegmons, diabetus sacralis, marasmus Observation It seems that hysterectomy was indicated on the sixth day

12 Normal labor, sepsis began on the fourth day, death on the fourteenth day Poor history

Autopsy puerperal sepsis, ichorous endometritis, thrombosis plexi pampiniformis, phlegmonous oöphoritis, diffuse fibrinous peritonitis, fibrinous and purulent left pleuritis Observation This case was one very strongly demanding hysterectomy It should have been done before pleuritis came on

12 The birth was normal, but there was great hemorrhage with icterus on the third day, with an infiltration of the left arm This was incised It discharged no pus but an edematous fluid On the fifth day a chill, on the ninth day parotitis Death on the tenth day

Autopsy puerperal sepsis, suppurative and fibrinous meningitis, phlegmonous oöphoritis, anemia, icterus gravidus Observation It does not seem likely that hysterectomy would have helped this case

Hochsetter[5] had during the year 1,719 confinements and 21 deaths

Puerperal fever, five, rupture of uterus, one, eclampsia, twelve, chronic nephritis, one, collapse, one, heart failure, one, total, twenty one

Septic infection with recovery 10, phlegmasia, 1, metritis, 17, perimetritis, 5, light puerperal fever, 104, fever from known cause, 46, total, 183 10 6 per cent of all Of these cases, 98 had syphilis

1 Multipara, age 38, eighth birth Two last births child was turned, owing to transverse position On admission, temperature 37 8, pulse 120, pelvis flat, abdomen lax and pendulous head retracted toward right, heart beat below navel, os admits two fingers Patient stated that waters had passed on previous day, consequently examined by midwife No pains, patient placed on right side, abdomen supported, producing appearance of head in os Following day no pain normal temperature Second day, morning temperature 37 8, evening temperature 38 9, pulse 104 to 110 No labor pains Pain in right inguinal region Third day, temperature 39 4 and stinking lochia, no tympany of uterus, chills, and temperature 41 Pains, extraction of child nearly dead, irrigation of uterus, fall of temperature, manual removal of placenta on account of profuse hemorrhage and weakness of patient, irrigation of uterus No hemorrhage, iodoform tampons in uterus and vagina Tampons removed on following day, temperature 38 to 38 5 Fourth day, chills and high fever, remittent, then continual, twenty nine chills Thirty sixth day after birth, death occurred

Autopsy diphtheritic endometritis, gangrenous, phlegmonous right parametritis Right ovarian thrombo phlebitis, thrombo-phlebitis of left renal vein and vena cava, multiple metastatic pneumonia Hyperplasia of the spleen, ulcerative endocarditis Observation Abundant time for hysterectomy

2 Primipara, 22, pelvic measure 25-27 5-30-17, 5-10 First stage of labor on first day, second day chills, temperature 39 9, pulse 120, contracted uterus, heart beats 192 to 200 stinking lochia Extraction of child with instrument, foul smelling child, irrigation of uterus before and after spontaneous expulsion of placenta, fever intermittent, then continuous, constant irrigation no relief, five chills, spleen, tumor and right sides parametric exudate Twenty-first day after confinement, death

Autopsy peritonitis, adhesive and purulent double left parametritis with phlegmons, diphtheritic endometritis, gangrenous metritis, thrombo-phlebitis, parenchymatous nephritis Observation Abundant time for hysterectomy

3 Multipara, 28, seventh birth Admitted after delivery of dead child on previous day Suffering from large condylomata Placenta ejected by pressure on abdomen, then removal Third day fever, irrigation of uterus, many coagulated blood masses removed from vagina, foul smelling, injury of vagina to left of cervix, irrigation of uterus continued, curettage, removal of decidual remains Temperature 37 6 to 38, pulse 110 to 120, ninth day chills temperature 39 3, profuse hemorrhage from genitals, digital exploration of uterus, removal of large piece of decayed placenta, irrigation of uterus Fourteenth day, death

Autopsy diphtheritic endometritis, parenchymatous nephritis, hepatitis, myocarditis, fibrinous right pleuritis, right hydronephrosis Broncho-pneumonia of the right lung Observation Abundant time for hysterectomy

4 Fourth day chills, temperature 40, high fever with moderate pulse Ninth day, to right of uterus painful resisting mass, lochia stinking Fifteenth day, incision of gluteal abscess, swelling of knee joint Two incisions on fourteenth day with much pus, fever continuous, few days later two abscesses opened on nates, twenty fifth day removed to other hospital, death four weeks after

Autopsy chronic suppurative perimetritis, psoas abscess, several para articular abscesses about the right knee joint and right shoulder joint parenchymatous nephritis and hepatitis Observation Hysterectomy should have been performed on the twelfth day

5 Primipara, 24, fifth day after delivery, chills, fever 40 5, pulse 132, irrigation of uterus, no result, continued high fever Sixth day, abdomen tender on pressure and distended, peritonitis Death on eleventh day

Autopsy suppurative and fibrinous peritonitis, parenchymatous, myocarditis, hepatitis, nephritis and gastritis, erysipelatous endometritis and edema of the parametrium Observation Hysterectomy should have been done on the sixth day

CONCLUSIONS

1 Puerperal sepsis still causes almost one-half the deaths occurring in the puerperal state

2 The causes of puerperal infection are the same as the causes of other wound diseases and should be treated on the same principles

3 Curetting and irrigation are unavailing when the infection has passed outside of the endometrium and submucous connective tissues of the uterus

4 The removal of the uterine appendages for infection outside the endometrium leaves behind the infected uterus from which the septic process goes on

5 Removal of the uterus and its appendages should be performed when puerperal sepsis has gone beyond the endometrium

6 The indications for hysterectomy in puerperal sepsis seem to be these (*a*), curetting and uterine irrigation and tamponade have failed, (*b*), peritonitis or pelvic cellulitis is present, (*c*), hopeless localization of infection outside the pelvis can not be found

7 Hysterectomy may not be helpful in the course of diphtheritic vaginitis and endometritis

8 Hysterectomy may not be available in cases of rapid early infection

9 Hysterectomy may not be helpful in cases of septic phlebitis reaching outside the pelvis

10 The method of operating will depend (*a*), upon the size of the uterus, (*b*), upon the condition of the uterine tissues, (*c*), upon the experience or choice of the operator

11 Except in early operations in which the uterus is still large and therefore difficult to manage through the vagina, the vaginal method with the clamps will be preferred because it is a more rapid method it is less objectionable in the public mind and it furnishes the best possible drainage

---

[5] Hochsetter Charite Annalen nineteenth year 1892-93

ROSS O SIDNEY, M D, of Brooklyn, died October 31, in his seventy fourth year from a brief illness by pneumonia He was for twenty five years a resident of Brooklyn, and at one time prominent in political affairs He was an alumnus of the class of 1848 of the University of Pennsylvania

JOHN LLOYD ZABRISKIE, M D, of Brooklyn, N Y, died suddenly while away from his home on the 11th inst, in his sixty fifth year He was the eldest son of Dr John Barren Zabriskie who married Miss Abby Lefferts Lott of Flatbush, a member of one of the oldest families on Long Island, she died in 1848 John Lloyd Zabriskie was born on August 26, 1841 in the old house of the Zabriskie homestead, which stood until a few years ago at the corner of Flatbush Avenue and Church Lane, just in front of the present family residence It had stood there for two hundred and twenty-five years and was the oldest house in Flatbush His early education was acquired at Erasmus Hall Academy He then entered Columbia College and took a literary course After graduating from Columbia he studied medicine with Dr J M Ingraham of Flatbush, who had been his father's most intimate friend and at the same time attended lectures in the New York Medical College and was graduated in 1863 In 18[illegible] he married Miss Eliza B Garvin, and their union has been a most happy one The friends of the dead man say that there was not in all Brooklyn a home more refined, more hospitable or more exemplary as to the purity and peacefulness of the family life than the Zabriskie home Although a busy physician, Dr Zabriskie found time to indulge his fondness for music He had a cultivated voice, and was an accomplished performer on the violin His sunny disposition, his kindness, sociability and his sincerity made him good friends everywhere He was a member of the Kings County Medical Society, consulting physician at the Kings County Hospital, a member of the Board of Education, an elder of the Dutch Reformed Church and a member of the Knickerbocker Field Club He had for many years been identified with the Medical Board of the Long Island College Hospital He has left a widow and three children, of whom two are sons who have elected to follow their parent in the medical profession One of the sons is at present studying pathology at the University of Berlin The cause of Dr Zabriskie's sudden demise is set down as heart disease, culminating in angina pectoris The profession has lost in Dr Zabriskie one of its stanchest and sincerest supporters

PUBLIC HEALTH

The Pasteur Institute of New York and Its New Serum Plant — It is reported that an out-of-town extension of this Institute will be made The conductors have made a purchase of thirty five acres near Tuxedo, on which will be established an experiment station It will be stocked with cows, horses, sheep, mules and goats, which will be bred with the express idea of producing antitoxin for the prevention of cancer and diphtheria This substance sells for a high price and its manufacture will be very profitable The station is well located, and one of its features will be a house in which the patients of the Institute will be treated A new station is to be established on the Erie Railroad near by, which will be known as Pasteur

A Miniature Hospital in the Home —In the *Practitioner* for September, Dr Malcolm A Morris, of London, favors the proposition that in planning a house, regard shall be had for the future needs of the occupants in the time of sickness His recommendation is that one room should be set apart in design as the sick room This room should be shut off as much as may be from the common atmosphere and common noises of the dwelling—or, rather, it should be so arranged that it can be shut off at any time—and there should be a bath room and water closet close at hand The walls and floors and other surfaces should be impervious, so as to harbor no impurities and to admit of ready cleansing, and the furniture and fittings should be simple, with the same object If in addition there should be a second room available for the nurse's use, the essentials for the proper seclusion of infectious cases are provided, as far as possible in a private house. A miniature hospital is then ready at hand, and at ordinary times it can serve as a spare room or even as a bedroom in regular use, differing only from any other room in its adaptability to the special purpose in question This plan should be especially welcome to the paterfamilias in whom the home feeling is active, and whose olive branches sprout out thick and fast To such an one the little private ward may be a positive and blessed economy in saving the doctor's bills that are apt to pile up where the children's diseases—as they are improperly called—take a run through the family This incentive is apart from the higher economy that may also take place, namely the saving of the lives of some of the juniors of the family

Health Reports.—The following health reports have been received by the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Michigan Detroit and Rochester, smallpox reported November 9

SMALLPOX—FOREIGN

Glasgow, October 19 to November 2, 9 cases
London October 19 to November 2, 5 deaths
Naples October 19 to November 2, 6 cases, 6 deaths
Odessa October 19 to November 2, 6 cases, 1 death
Warsaw October 12 to 19, one death
Montevideo October 5 to 12, 5 cases, 3 deaths
Buenos Ayres August 1 to 31, 41 deaths
Dublin October 26 to November 2, 3 cases, 1 death
Buda-Pesth October 21 to 28 2 cases
Calcutta September 21 to 28, one death
St Petersburg, October 19 to 26, 3 cases, 3 deaths

CHOLERA

Bombay October 8 to 15, 2 deaths
Calcutta September 21 to 28, 35 deaths
Yokohama September 20 to October 11, 10 cases, 9 deaths.
Austria Hungary, October 15 to 21, 57 cases, 32 deaths
Russia Volhynia Govt September 1 to 7, 4 237 cases, 1 668 deaths, September 8 to 15, 8 554 cases, 1,417 deaths, Podolia Govt, September 1 to 15 51 cases, 10 deaths, Primorstajahezirk (Siberian Russia), July 30 to September 18, 82 cases, 58 deaths
Egypt Damietta, October 11 to 16, 15 cases, 8 deaths

YELLOW FEVER

Cuba Santiago October 26 to November 9, 29 deaths; Sagua la Grande, October 26 to November 2, 8 cases, Cienfuegos, November 3 to 10, 1 death

BOOK NOTICE

The Diseases of Children's Teeth, their Prevention and Treatment A Manual for Medical Practitioners and Students By R DENISON PEDLEY, M R C S, L D S, F R C S Illustrated 8vo, cl London J P Segg & Co Philadelphia The S S White Dental Mfg Co

This work is intended to supply information on the nature and treatment of diseases of the teeth to students and general practitioners of medicine More particularly, says the author, for those who "settle down in the country where the area of practice is wide and the opportunities of obtaining skilled dental assistance are few " Notwithstanding the fact that it was particularly intended for the especial class mentioned, yet it is evident on inspection, that the work may be read by many dental and oral surgeons with profit While American dentistry has forged ahead in the international race for superiority with gigantic strides, still we suppose our practitioners may be interested in the elementary work of our British cousins—but the general practitioner of medicine who can not and does not wish to reach the high plane of the metropolitan dentist, will find that there is very much to interest and instruct him in this little volume, indeed we scarcely know what other work "fits that particular niche" with such nicety

POST-TYPHOID BONE LESIONS

Typhoid fever may have many sequelæ, and not the least interesting and important of these are the post-typhoid bone lesions which have attracted considerable attention, both before as well as after the discovery of the specific cause of typhoid fever As would be naturally expected, the identification of the EBERT-GAFFKY bacillus as the specific cause of typhoid fever has been followed by a thorough investigation of the post-typhoid bone lesions and the results have established an undoubted relation between them and the primary typhoid attack

EBERMAIER[1] obtained the bacillus of EBERTH in pure culture from two instances of suppurative periostitis following typhoid fever ORLOFF[2] and ACHALME[3] found the same bacillus in pure growth under the same conditions Others have made similar observations PEAN and CORNIL[4] describe necrosis of the tibia, occurring eight months after recovery from typhoid fever, in which the bacteriologic examination showed the typhoid bacillus associated with other organisms, and FASHING[5] and E FRAENKEL[6] both found the typhoid bacillus associated with pyogenic microbes under *similar conditions* Then there are also examples of post-typhoid bone affections associated with the pyogenic cocci only Such post-typhoid inflammatory and suppurative lesions in the bones may consequently be produced by the ordinary or less common pus microbes alone or associated with the bacillus of typhoid fever and careful investigations have also shown that they may be caused by the latter microorganism alone

Naturally, the question of the pyogenic properties of the typhoid bacillus is of much interest in connection with the sequelæ ORLAFF[7] and ADENOT[8] both caused suppuration in dogs and rabbits by the subcutaneous inoculation of pure cultures of the typhoid bacillus More recently this problem has been subjected to an elaborate experimental investigation by DMOCHOWSKI and JANOWSKI,[9] and these workers reach the apparently incontestable conclusion that there is no animal tissue in which the bacillus typhosus may not cause suppuration under suitable conditions Inasmuch as the pyogenic staphylococci and streptococci cause suppuration in various tissues only under what may be called suitable circumstances, it follows that the typhoid bacillus is similar to them in this respect, and it may be said that it is now settled beyond all doubt that the bacillus of typhoid fever when in possession of a certain degree of virulence, possesses distinct pyogenic properties

A satisfactory explanation of the occurrence of bone lesions after typhoid fever has not as yet been advanced, but many valuable observations bearing on this point have been made Thus QUINCKE[10] demonstrated the presence of the typhoid bacillus in the spleen and the bone marrow, especially the ribs, as late as the seventh week of the disease In nine cases examined, eight showed the organism in the rib marrow It has also been shown that this bacillus has a very marked tenacity of life outside of the body Now these points certainly throw some light on the development of post-typhoid bone lesions at periods long after the attack of the febrile disease, but the causation of a distinct necrosis in one instance and not in another is the problem that baffles all efforts at explanation

Very recently PARSONS[11] reviews this subject of post-typhoid bone lesions and describes six cases observed in the surgical clinic of the Johns Hopkins Hospital Four of these six cases were in men and two in women The period after recovery from typhoid fever at which the lesions appeared varied from one to sixteen months The character of the typhoid attack did not bear any relation to the occurrence of the bone changes It is interesting to note the general fact that the symptoms of the bone infection, almost without exception, come on some time after convalescence has been well established In one case[12] only did the bone changes manifest themselves during the course of the fever In PARSONS' *cases the lesions* were situated in the ribs or the costal cartilages in three instances, in the tibia once, once in both tibiæ, and once in the left radius and the right tibia

From the cases described in the literature it appears that almost any bone in the body may be involved, but that the tibia is undoubtedly the bone of choice, the instances in this situation greatly predominating, whereas the hands and the feet are remarkably free

From the bacteriologic notes accompanying the cases described by PARSONS, it is seen that the typhoid bacillus was present in pure culture in four out of the five cases that were examined, the remaining case was one of mixed infection, a focus in the radius showing the typhoid bacillus associated with the staphylococcus pyogenes citreus, and a focus in the tibia the staphylococcus pyogenes aureus only

Usually, the first symptom of a post-typhoid bone lesion is pain Sometimes this will be complained of while the patient is still in bed convalescing from the typhoid fever, at other times the pain will appear soon after getting up and about The pain is usually localized and almost invariably involves the region subsequently the seat of the necrosis This pain has been likened to the bone pains of secondary lues Usually, this pain subsides and may leave a little soreness over the formerly painful spot Simultaneously with the pain, a slight swelling usually occurs which disappears with the subsidence of the spontaneous pain Now, in some cases the trouble soon recurs with pain, swelling and indications of necrosis, in others this may be delayed for months, in other cases, again, there may be repeated exacerbations and remissions that never seem to be followed with necrosis As a rule, there is an entire absence of fever, and the clinical course is marked by a peculiar chronicity

In one of the cases described by PARSONS, the swelling that formed underwent resolution, it had appeared during convalescence just above the left costal margin, eight months post typhoid it again appeared and subsided to make its third appearance about one year after the onset, after which it disappeared again leaving a painless induration

The chronicity of this post-typhoid process in the bones, which seems to be a characteristic feature especially of those cases that are found to be due to a pure infection with the typhoid bacillus, has caused it to be considered by some as analogous to the cold suppurations of tuberculosis and the necrosis of syphilis Histologic examination of the diseased tissue has failed to reveal anything that could be considered characteristic of, or peculiar to, these lesions, although some authors speak of the changes due to the typhoid bacillus as partaking more of the nature of a pure necrosis than of typical suppuration as shown by the examination of the pus, the usual appearances under the microscope show a marked round cell accumulation with a greater or less leucocytic infiltration

The diagnosis of such cases would rest largely upon the history of a previous typhoid fever, or perhaps of some indefinite continuous fever The occurrences of inflammations in bones during or after convalescence is suggestive of a pure typhoid infection, whereas the mixed infections in bone and soft parts, and the typhoid infections in the soft parts are seen more frequently during the course of the disease

As a rule, the prognosis is good, although a fatal case of disease of the femur showing association of typhoid and colon bacilli has been reported by KLEMM[13]

Complete excision of all the diseased and suspected tissue appears to be the most satisfactory treatment Mere excision is not sufficient, because it has been so often found that the microorganisms will persist in the wound for an almost indefinite length of time

THE PHYSICIAN IN OREGON

The legislative assembly of the State of Oregon, in its 1895 session, passed a new law for the regulation of the practice of medicine and surgery, which, in some of its features, is of more than local interest Among other things, it provides that the Governor shall appoint five persons from among the most competent physicians of the State, all of whom shall have been residents of the State for seven years and of at least five years' practical experience in their profession, who shall be known as the Board of Examiners for the State of Oregon Three of the board shall be regulars, one "eclectic" and one "homeopathist" The full term of office is five years The board is required to hold meetings for examination on the first Tuesday of January and July of each year, at Portland, and it may call special meetings when in the opinion of a majority of the members it is deemed necessary

Examinations shall be in anatomy, physiology, chemistry, materia medica, therapeutics, practice of medicine, surgery, obstetrics, diseases of women, medical jurisprudence and such other branches as the board shall deem advisable They must be both scientific and practical, and of sufficient severity to test the candidates' fitness to practice medicine and surgery They may be by written or printed, or partly written and partly printed, questions and answers

The board may refuse or revoke a license for unprofessional or dishonorable conduct, subject, however, to the right of the applicant to appeal, from the decision of the board, to the circuit court And before a license can be revoked, a complaint of some person under oath must be filed in the office of the secretary of the board, charging the acts complained of, the accused must be served with a written notice and copy of such complaint, a time and place for hearing thereon appointed, and stated in the notice, and the accused be given an opportunity to appear and

defend himself, personally and by counsel, have the sworn testimony of witnesses taken and present other evidence in his behalf

The words "unprofessional" or "dishonorable conduct," are declared to mean 1, the procuring or abetting in procuring a criminal abortion, 2, the employing of what are popularly known as "cappers" or "steerers," 3, the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured, 4, the willfully betraying of a professional secret, 5, all advertising of medical business in which untruthful and improbable statements are made, 6, all advertising of any medicines, or of any means whereby the monthly periods of women can be regulated, or the menses reestablished if suppressed, 7, conviction of any offence involving moral turpitude, 8, habitual intemperance

The person receiving a license shall file the same, or a copy thereof, with the county clerk of the county wherein he resides, and in case he shall move into another county, he shall procure from the county clerk a certified copy of such license and file the same with the county clerk in the county to which he removes

The penalty for practicing medicine or surgery without a license, or contrary to the law, is a fine of not less than $50 or more than $100, or imprisonment in the county jail not less than ten nor more than ninety days or both such fine and imprisonment All fines are to be paid into the State treasury for the use and benefit of the common schools

Any person shall be regarded as practicing medicine within the meaning of this act who shall append the letters "M D" or "M B" to his or her name, or, for a fee, prescribe, direct or recommend for the use of any person, any drug or medicine or agency for the treatment, care, or relief of any wound, fracture or bodily injury, infirmity or disease, provided, however, the act shall not apply to dentists in the practice of their dental profession

THE CRIMINAL BRAIN NOT NECESSARILY DEGENERATE

At the Philadelphia Academy of Natural Sciences the subject of degeneration was discussed recently by the Section on Anthropology **Dr Charles K Mills** presented the brains of three murderers and demonstrated in them the abnormalities in the course and development of convolutions and fissures, apparently showing a reversal to the brain conformation of anthropoid apes Two of the murderers were insane, which also was indicative in the mind structural peculiarities

Dr M V Ball dwelt upon the distinction between the "degenerate" and the "atavistic" brain, the former being pathologic, the latter the result of reversion to a lower type Idiots, insane and epileptic subjects belong to the degenerate class, while, according to **Lombroso**, born criminals are the result of a halt in evolution, or what is termed reversion Some criminologists maintain the view that the changes are due to faulty nutrition, and as criminals are usually of the pauper classes, the fault, in that case, would be primarily social

Prof D G Brinton declared that because a man's brain showed characters of a lower type, it need not be inferred that he was necessarily criminally inclined The lower races are often as ethically elevated as many civilized races, and furthermore, men of honest habits may possess brains exhibiting the anomalies referred to Crime is not so much the result of anatomic, as it is of social conditions, if it were solely physical, we could do little toward improvement, whereas we know that crime can be reduced by better social advantages and an improved environment

Professor Cope expressed his belief that physical organization does control action, but an unfavorable environment acts by developing degenerate and physically inferior individuals Society may do much toward improving the human race by preventing the physically degenerate from reproduction

Prof L Witmer exhibited a cast of the brain of **Laura Bridgman**, who in the physical sense was a degenerate, though morally and intellectually of high culture and development Some of the characters of the alleged criminal brain were present, and there was deficient development of the centers in the cortex where the faculties of sight, speech and hearing have been located, showing that degeneration here was to be traced to disease of the sense organs

Prof Ernest Laplace said that he had examined the brain of **Gambetta** shortly after his death, and though a very small brain, comparable in size to that of an idiot, it was strongly developed in the region of the speech centers, which corresponded with his great oratorical ability during life Criminality, according to **Professor Laplace**, is an exaggeration of selfishness, and he suggested that a center for selfishness may some time be determined

Prof Harrison Allen spoke of the non-permanence of peculiarities of brain structure, and said that they constantly tend to return to an earlier type of formation Man is a domesticated animal and like other domestic animals has a tendency to revert to a more primitive condition He maintained that because ape like characters are found in a brain, we have no right to assume that the person's actions during life were ape-like any more than we have to assert that those which showed features which are found in the hog are necessarily hog-like The brain may exhibit apparent abnormalities or peculiarities without proving anything against the moral character or mentality of the owner

THE CORRESPONDENCE OF THE INSANE

The latest report of the New York State Commission in Lunacy contains two letters from the Assistant Postmaster General, giving the opinion of the Department in regard to rights of the insane, and others under legal detention, in the matter of their correspondence The question often arises with asylum physicians as to how far they are justified in withholding or examining letters sent to inmates when, for good medical or other reasons, this seems imperative or advisable According to the ruling of the Post office Department, they have the right to withhold letters from patients when it seems necessary to do so, but the right of examination is not specifically stated though it seems to be inferred by the New York Commissioners

The safe statement of the case seems to be thus the legal and natural guardians of the lunatic, and lacking such the asylum authorities, have the full right to say whether or not he shall receive letters, but whether they can open and inspect them without his consent, may yet be a question for decision by the Department

As regards the sending of insane patients' letters, there should be no legal question—it ought to be left entirely to the judgment of the physician in charge Some years ago, it is said a recovered patient in England brought suit for damages against a doctor for mailing his insane correspondence, and it is not hard to see a possible reason in his complaint There is, nevertheless, an almost perennial movement in our various State Legislatures for enlarging the freedom of the insane in this direction For example, a few years ago, a bill was introduced into the Illinois Legislature to allow every inmate of a State hospital to select a correspondent with whom all communications either way should be inviolate The bill had perhaps a fair prospect of becoming a law until its possible consequences were practically demonstrated by samples of insane correspondence to the committee that had it in charge

The chances for serious consequences from too lax an oversight of the letters sent out by lunatics are real, and very serious mischief has been done in this way A few years ago, the authorities of the Willard Asylum were embarrassed by the arrival of a whole family from Europe who had broken up their home, sold out their interests and came there on the representations of a megalomaniac inmate, only to find themselves the victims of the delusions of a lunatic The still more probable possibilities of libelous statements and improper communications are also to be borne in mind, as well as the mortification any right minded person would feel on recovery or in lucid intervals, in knowing that such evidences of his disorder had been allowed to go abroad It was this last consideration that was the basis of the English suit already referred to, as stated in the account of the case given at the time

The matter is one that is of interest, not merely to asylum officers, but to any medical man who may be consulted in regard to the management of the insane It is well that, in view of the coming legislative sessions, medical influence and opinion should be firmly against any pseudo-philanthropic measures that are against the best interests of those they are ignorantly intended to serve

THE MEETING OF THE TRUSTEES

The semi-annual meeting of the Board of Trustees was held November 16 Only two members were absent and the meeting was a harmonious one All regretted that the illness of Dr Reeves prevented his attendance The Treasurer's statement showed a larger balance in the Association treasury than for several years past, and the editor's report, printed in another column, told the story of the year's prosperity The Board took measures for increasing the number of subscribers, and the membership of the Association, and for the betterment of the equipment of the Journal The allowance of $400 for the expenses of the Committee on the Department of Public Health was made in accordance with the resolution of the Association at the Baltimore meeting, and will furnish that committee with a sum sufficient to carry on an active canvass during the winter

The great improvement in the Journal and its affairs will not induce the management to remain quiet, but, on the contrary, only operates to encourage renewed effort The Association, in founding the Journal, had no intention of making it a commercial enterprise, and the only legitimate object of the money in the treasury is to make the Journal better and better, as fast as its funds will allow, so that the members may receive the benefit in the form of an improved publication

Our readers will be glad to know that Secretary Atkinson has completed a card index to the first twenty volumes of the Journal, and the Trustees have ordered it printed in book form, which will be sold at a nominal price

This index will follow the index to the thirty volumes of the Association, issued by Secretary Atkinson when the annual volume of Transactions was suspended and the publication of the Journal wa begun by a Board of Trustees with N S Davis Sr as editor From that day to this, there has scarcel been a break in the steady progress of the Journa of the American Medical Association, and we ca truthfully say that, notwithstanding the great finan cial depression of the past three years, few busines enterprises have prospered more than our Journal Let the fact, as it stands, encourage the members t go on with the good work of organization, until ou Association stands first in membership of any in th world, as it is now first in America!

CORRESPONDENCE

A Case of Malignant Hemorrhagic Malaria with very Large Spleen

Elgin, Ill , Nov 15, 1895

To the Editor —With the permission of Dr J F Bell, I wish to report an interesting case of hemorrhagic malaria in which I was called in consultation

W M , male, age 25, recently from a malarial region of Kentucky and for years a victim of that disease He has had several chills during his three weeks' residence here, of the remittent form October 27, last, the patient left the house feeling very well, not having had a rigor during the last week While waiting in the depot for a train to Chicago, he suddenly became quite sick He struggled back to the house and on reaching it he fell to the floor, complaining of pain, and also had a chill Dr Bell was called, and found the patient in a delirious state, temperature 104, pulse 130, strong and full , palpation and pressure over the spleen and liver was resisted by the patient , percussion revealed increased dullness of both organs , the Doctor prescribed quinin in large doses frequently, sponge baths and opium as a sedative I was called a few hours later and found that the patient had passed a very large quantity of sanguineous urine, had also vomited a fluid substance of a very blackish hue The vomited matter was not saved, so could not tell what the nature of it was His temperature had increased to 105, fluid extract ergot ʒss doses every two hours ordered *for the hematuria Dr Bell called again about four hours* later, patient being no better, fever and hematuria still persisting I saw him at 9 30 that evening with Dr Bell Temperature was 105 5, pulse 140, skin very hot and slightly icteric, sclera yellow He was quite restless and still delirious His brother exhibited a chamber vessel which was about half filled with sanguineous urine which patient had passed during the last five hours Pot bromid gr xv, chloral hydrat xv was ordered to be given every two hours until sleep was *produced The treatment of the morning* kept up and ice cap applied He passed a very restless night Dr Bell and I saw him several times during the next day During the early morning hours he became very much jaundiced, the entire body being of an intensely lemon yellow color Resorting to the various antipyretics, cold, enemas, ergot in smaller doses more frequently did not seem to check the temperature or hematuria He became so restless that restraint was required to keep him in bed, and was much worse about 3 p m , at which *time his temperature* per axilla was 107 25 with a quick running pulse He died at 4 15, thirty one hours after attack

I made an autopsy on the remains about twenty hours after death, assisted by Drs Albert Swartz and J F Bell, and found on external inspection a young man of great muscular development No emaciation, skin of a bright lemon hue, also conjunctivæ , rigor mortis very pronounced. Examination of the organs followed Pericardium contained a greater quantity of fluid than normal A stringy, colloid sticky and thickened material was found to extend into the aorta and after removing it was found to be about a foot in length and corresponded to the rounded shape of that vessel , insufficiency of aortic valve, otherwise heart was about normal in appearance weight and size Lungs were congested more marked on lower lobes Liver greatly enlarged, of a dark reddish brown appearance, capsule slightly thickened, on cut surface of a yellowish brown color filled with pigment, and cutting with more resistance than usual Gall bladder full of fluid no concretions , openings and ducts patent The spleen was nine inches in length, six and one-half in breadth and three inches thick, weight 1 630 grams, of a grayish-brown color , capsule not thickened The parenchyma, soft, of a dark brownish color and impregnated with pigment Kidneys enlarged, swollen and congested , capsule slightly adherent , cortical markings indistinct The medullary substance of a dark grayish-red color with scattered areas of pigmentation Stomach contained a quantity of dark greenish fluid Bladder also contained a quantity of sanguineous urine

I will add that the cutting of the skin was accompanied by a raw leather like resistance to the knife, also cutting the serous surface was like cutting cartilage

H J Gahagan, M D ,
Assistant Physician, Illinois Northern Hospital for Insane

A Specific for Spasmodic Croup

San Diego, Cal , Nov 16, 1895

To the Editor —Among the remedies for acute laryngitis suggested in a recent and elaborate contribution to the Journal, I am surprised that no mention is made of the oleoresin improperly called "balsam" copaiva I regard its employment as quite an advance on the antiquated ipecac, turpeth mineral, *et id omne genus* treatment, and for many years I have used it to the exclusion of all such Preferably, it should be given in a full dose of 15 or 20 drops to a child 2 or 3 years old, at bedtime, or immediately following the first hoarse inspiration or cough This will generally carry the little patient through the night, or certainly until the early morning hour, when a recurrence of the paroxysm is often expected *En capsule* is the best method of administration, for the purpose of disguising the unpleasant taste The syrup of copaiva prepared by rubbing the oleoresin with calcined magnesia, and adding oil of peppermint and simple syrup, is an eligible formula Less so, is an emulsion with mucilage, yolk of eggs, or alkalies The required doses, however, are so few, and time often of such importance, that I commonly extemporize a combination of the remedy with sugar or molasses The element of fear of suffocation usually renders the little patient quite tractable, so that he gracefully submits to almost any form of medication at such times I can yet recall, *ad nauseam*, the not infrequent doses of ' hive syrup" of my youth

In the presence of a severe attack, I give the copaiva *imprimis*, and then transfer the child, if in a cold room, to the nursery or kitchen, where he is subjected to heat and steam A shawl thrown over the heads of nurse and child, as well as over the teakettle, is a ready method The first whiff of steam relaxes the spasm, if the remedy has not already done so, and the crisis is past The child should be detained in a warm room for the two succeeding days and nights, taking similar or smaller doses each evening upon retiring, and, if thought best, a few drops at intervals during waking hours

By this method the system is not relaxed with a tendency to contract additional cold and I am sure it will supply a long-felt want to paterfamilias if not to his progeny

C M Fenn, A M , M D

ASSOCIATION NEWS

Report of the Editor to the Board of Trustees

Semi annual Meeting held in Chicago Nov 16 1895

[Published by order of the Board]

TO THE PRESIDENT AND MEMBERS OF THE BOARD OF TRUSTEES

Gentlemen —I have the honor to report that since your last account the affairs of the Journal have progressed smoothly, the only serious annoyance being the difficulty of readjusting our plan of advertising Fortunately the Chairman of the Committee on advertising was easily accessible, and the cases in doubt were referred to him As a report may be expected from that member, I will not further dwell upon the subject, except to say that we are applying the Association rule absolutely with regard to all *new* advertisements Many old ones cheerfully furnished the formula, and those that have not furnished the formula, have been informed that the Journal could not renew their contracts without their full compliance with the rule I caused slips to be printed, of which the following is a copy

TO ADVERTISERS

The Board of Trustees adopted, and the Association by unanimous vote approved, the following order

"Hereafter advertising of medicinal preparations in the Journal shall be limited to those advertisers who furnish for publication in the Journal the official or chemic name and amount of each ingredient contained in the said preparation "

The Journal of the American Medical Association

This is sent to all advertisers and advertising agencies when inquiry is made concerning an advertisement

The value of advertisements that have been dropped under the rule, is $910

The value of advertisements that will not be renewed on account of the rule, is $2,388 10

Advertising orders refused, $345 60

The amount of changed advertisements by furnishing formulæ is $2,151 20

Contracts for $1,003 20 are being held awaiting action

The income of the Journal, May 31 to October 31, from various sources, is $10,683 34.

The regular issue of the Journal has now reached 6,200 copies, and last week was 6,400 It will be seen (from the detailed statement) that the receipts from subscriptions are growing steadily, but do not show the real amount nor the increase, as many of the new subscribers are transferred to the membership list within a few weeks after receiving the Journal The Treasurer of the Association receives the money from this class You will be pleased to note that the balance in the Association Treasury has been steadily increasing, and notwithstanding our increased expenses on account of enlargement of the Journal, the balance is larger than at any period in the last four years The eight page enlargement of the Journal last year proved inadequate to the relief from the pressure of manuscript, and another enlargement was made whereby the average number of pages of reading matter has been raised to fifty-two For the present, I think the Journal large enough, but sixty pages a week should be the eventual goal That will allow an increase of matter sufficient to prevent criticism on the part of those who are not interested in specialties and do not like to see so much space given them, by providing an abundance of reading matter for all

The increase in the subscriptions since the Baltimore meeting has been made by personal letters written by Dr Montgomery in Pennsylvania, similar letters written by the editor in accordance with a suggestion made by Dr E Fletcher Ingals, and by a traveling solicitor

The advantages of the plan of canvassing can scarcely be estimated in dollars and cents, for the work may give results months after the solicitor has made his visit Beside, most of the subscribers eventually become members of the Association We now hold applications waiting the receipt of the necessary remittance There have been very few discontinuances, a marked contrast from the conditions when I assumed the office

The property of the Journal office is now worth $10,000, a plant which has been wholly purchased within the past two years except the type An expenditure of $1,200 for new type, and $1,000 for new automatic folder, will be necessary during the next six months Much inconvenience would be saved the mechanical department by having the type asked for It is especially necessary when we run the large number of pages, as proofs must be sent to contributors and the type held An iron chest or cabinet for holding manuscript should be furnished, unless we move into a building having a vault

The quarters are entirely unsatisfactory We have to pay high insurance rates, and the persons in control of the building have not put it in repair as was agreed upon I request to be allowed to look for other quarters by the time of the expiration of the present lease in April next, or sooner, if arrangements can be effected without loss

The elevator service could scarcely be worse than it is now, and the shaking of the building when the machinery is running gives an impression of insecurity, which is confirmed if the window-sills and walls be examined

At my solicitation, the Secretary of the Association, Dr. W B Atkinson, has prepared a card index to the whole of the Journal down to December, 1894 The instructions of the Board do not say whether to print in the Journal or in book form In my opinion the index will be more convenient in a book The estimated cost of 1,000 will be about $500

I have to commend the employes of this office for their faithfulness and industry Seldom have I seen an establishment where every person employed seems to have a personal interest in the growth and success of the business, but I have to report that that feeling is the rule in this office, and I have frequently noticed their actual enthusiasm in promoting the success of the Journal within their respective lines

Finally, I have to thank the Trustees for their encouragement and support, and the patient attention given to the various questions coming before the office for settlement

Very respectfully, John B Hamilton, Editor

SOCIETY NEWS

College of Physicians of Philadelphia—A stated meeting of the Section on Ophthalmology was held in the Lower Hall, College of Physicians of Philadelphia, Oct 15, 1895, Dr. Wm F Norris, Chairman presiding Present, Drs Fenton, Harlan, Norris, Oliver, Ring, Risley, de Schweinitz and Zeutmayer, Fellows of the College, and Drs Keely, Leahman, McGuigan, Pancoast, Posey, Rogers, Schwenk, Shoemaker, Stevens, Thorington, Wetherill, Worrell of Terre Haute, Ziegler and Zimmerman as guests

Dr George de Schweinitz described a case showing angioid streaks in the retina, and exhibited a water color sketch of the ophthalmoscopic conditions

Dr Charles A Oliver gave a brief report of the history of a case of successful iridectomy and extraction of lens capsule and lens débris with recovery of vision in an eye that had been considered useless for more than ten years Dr Harlan gave a short account of a somewhat similar case where the accident dated back some thirty-three years, and in which the patient's vision was fully restored By invitation Dr P U K Schwenk read the details of Dr. Harlan's case

Dr S D Risley exhibited a new and compact case for ophthalmic instruments The case was made of aluminum and white mahogany and had adjustable compartments for sterilizing apparatus

Dr Oliver exhibited two cases, one of successful iridectomy for congenital zonular cataract, in which vision was increased for the first time in the patient's life, from finger counting at 35 centimeters to five thirty-fifths, and the other showing the final results of operative treatment in a case of subconjunctival dislocation of the lens, in which vision was restored to full acuity

The Section then went into executive session Upon motion adjourned Charles A Oliver, M D
Clerk of Section

Harrisburg Academy of Medicine—The formal opening of the Academy of Medicine, founded by the Harrisburg Medical Society, took place at Harrisburg, November 7, the new building, a roomy brick and brownstone structure, being crowded The program began with appropriate remarks by Dr E H Coover Dr John Curwen, superintendent of the State Hospital for the Insane at Warren and ex-president of the Dauphin County Medical Society, made a few congratulatory remarks Then Governor Hastings was introduced, and discussed briefly the relation of the medical profession to the Commonwealth The Governor always makes a good speech, and he was roundly applauded by the assembled doctors and their guests "Why a Community should support a Medical Library" was the subject of an interesting address by Dr H C Wood, professor in the medical department of the University of Pennsylvania He gave reasons in support of his subject and happily illustrated his points "Some Physicians in the Past Century of Dauphin County" was the subject of the historical address by Dr W H Egle, who gave brief sketches of the more prominent men in the medical history of the county and referred to their characteristics The formal exercises were closed with the benediction by the Rev Dr Stewart This evening at 3 o'clock, a banquet in connection with the opening of the Academy, took place at the Chestnut Street Hall, which was decorated for the occasion There were numerous toasts

MISCELLANY.

Tonsillitis of Malingerers—According to *Le Progrès Medica* the following unusual development of malingering has bee observed at a French garrison-hospital A French dragoo who was lying in the garrison at Compiègne, and who wante a vacation, persuaded a male nurse to blow a little powdere cantharides into his throat The result, the next day, was tonsillitis with pseudo membranes, and the patient was sent to the hospital He was treated for eight days, and then was discharged well No cause for the disease could be discovered, and as he was not sent home to convalesce as he had expected, the nurse fixed him another attack, but was taken sick at the same time The attending physician thought this mysterious and one day a tobacco pouch was found in the nurse's bed filled with cantharides powder The affair was brought before a military court, the nurse received six months' imprisonment, and the dragoon was sent to an African regiment

Union in Nerves by First Intention—According to the *Deutsche Medicinische Wochenschrift* for July 4, Gluck presented before the Berlin Medical Society the case of a child of a year and a half, operated on May 7, for extensive tuberculosis in the right radius In the operation the radial nerve was severed After careful disinfection the nerve was sutured and then the external wound closed Union of the wound by first intention resulted After fourteen days the first symptoms of restoration of the nerve were shown, and about four weeks later the functions of the muscles supplied by the radial nerve became normal It is believed this is the first recorded instance of primary union in human nerves Experimental investigations on animals show that after such nerve suturing, a portion of the nerve filaments retain their vitality

A Medical Contributor to Ethnology—Dr Walter J Hoffman, of the Smithsonian Institute's Bureau of Ethnology has given to the world a book, entitled ' The Beginnings of Writing," and intended to trace the first steps in the development of writing among the North American Indians Dr Hoffman has been a diligent student of American ethnology, was with Lieutenant Wheeler's expedition into Nevada and Arizona in 1871, post-surgeon in Dakota in 1872, when he was able to study the ethnology of the Sioux, and later, in connection with Professor Haydon's survey and in the Bureau of Ethnology, continued work and study among the American Indians The publishers' notice says "Professor Hoffman, one of the most successful workers in the field of American ethnology, presents the first steps in the development of writing, from tangible reminders like quipus and wampum belts, through picture writing to phonetic writing with an alphabet These first steps are described especially as they are shown among North American tribes Our native peoples made much use of reminders, they drew truly expressive pictures, they developed complicated systems of pictography, and some peoples of Mexico and Central America were passing from the use of ideograms to phonograms This transition period is most interesting" In clear and popular language, Professor Hoffman sets forth the latest results of scientific study and his references are illustrated with many helpful pictures

Lesions of Fatal Electrical Currents—An article in the *Lancet* for August 31, gives an abstract of a recent paper by Dr Kratter on this subject His report was made to the Styrian Medical Society The case examined by him was that of a workman who was killed by a shock received while he was occupied in stringing telegraph wires Post-mortem examination, performed twenty one hours after death, showed a ruptured blister on the left forefinger, marked rigidity and intense ecchymosis on the dependent parts of the body There was also hypervenosity of the blood, venous engorgement of the lungs extravasation of blood into the common sheath of both the carotid arteries and the vagus nerve, and symmetrical hemorrhage along the spinal cord If an electric current of 1,500 volts acts upon rabbits some of the animals live and others show typical symptoms such as tetanic contraction of all muscles and instantaneous stoppage of respiration, the heart, nevertheless, continuing to act There may also sometimes be found disorganization of the brain, with destruction of the peripheral parts of the cortex and intracranial effusion of blood The stoppage of the respiration lasts half a minute From these experiments it results that the first effect consists in permanent or temporary arrest of the respiration Death from electric shock is, therefore, a form of suffocation, and persons who meet with such an accident are to be treated by artificial respiration, as in ordinary cases of suffocation

Must Show Authority for Removal of Cadaver—"If any person without lawful authority, dig up, disinter, remove or carry away any human body," a statute of Iowa proclaims, he shall be punished, etc One night certain parties were apprehended while dragging a dead body on the ground by means of a rope around the neck and arm attached to a hack They were armed with revolvers, and had opened the grave and removed the body in a secret and clandestine manner On appeal from a conviction of one of the men, it was urged that the trial court erred in instructing the jury that, where one who has disinterred or removed a dead body from its resting place seeks to justify the act he must show that he had a lawful permit from the State Board of Health If it be conceded that it was error to direct the jury that the subject of disinterment and removal of the dead was under the control of the State Board of Health the Supreme Court of Iowa holds, in the case of State v Schaeffer, decided Oct 2, 1895, that the instruction was clearly without prejudice, because it was not incumbent on the State to prove the negative fact that the defendant had no authority to do the act And, even if that burden was on the State, the proof of the criminal intent and the want of authority was manifest from the manner in which the act was performed It was incumbent on the accused to show that he was not criminally liable for the act, because he was within the exception in the statute, if such were the fact

Obligation of Town to pay Physician—That a town may be liable on an implied contract for services rendered by a physician to a pauper seems to be well settled in Wisconsin Notice to one of the supervisors of the town also seems to be sufficient to create the contract But in the case of Beach v Town of Neenah, decided by the Supreme Court of Wisconsin, September 26, 1895, the town denied all liability The evidence was to the effect that the physician who brought the suit had seen the chairman of the board of supervisors of the town in relation to the matter, and told him that there were at that time four or five sick in the family in question, and that they were in need of everything, and that they would have to have help, that the chairman said that he would see to it that they should have whatever they needed, and that the chairman knew that this physician was attending the family, who thereafter continued to treat them as a physician In the circuit court a nonsuit was granted on the ground that this evidence failed to establish an express contract of employment But the supreme court reverses its judgment, and orders a new trial, holding that upon such evidence it was for the jury to say whether the supervisor so notified acquiesced in the employment of the plaintiff or impliedly agreed that the town should pay for his services after such notice

Meningitis in the New-Born Due to Umbilical Infection—In *Pediatrics* the above subject is reported upon briefly as having been discussed at a Section meeting of the New York Academy of Medicine

"Dr Ira Van Gieson reported the only two cases of acute exudative meningitis that had been observed in the new-born in the Sloane Maternity Hospital, as a result of infection from the umbilicus These cases were very carefully recorded, including the results of a bacteriologic examination On inspection there was no evidence of any abnormal condition about the umbilicus, but on dividing the umbilical vein, this vessel was found to contain pus Pure cultures of the streptococcus pyogenes were obtained from the meninges and from the umbilicus, and microscopic examination showed a severe acute exudative meningitis No other lesions were observed Dr Tucker said that he had seen several cases illustrative of this remarkable fact, that the pathogenic bacteria in their passage from the umbilicus may pass by certain viscera, and ultimately find a lodgment in some remote part The only effective treatment for these infections in the new-born was a prophylactic one, and this consisted in carefully dressing the umbilicus with a dry, clean powder Dr Fruitnight said that in the earlier years of his practice when moist dressings for the cord had been in vogue, he had seen suppuration of the umbilicus much more frequently than since he had adopted the practice of using dry dressings

Chinese Testimony Regarding the Japanese Red Cross—Colonel Cockerill, of the *New York Herald*, sends from Japan a narration by a Chinese officer concerning the operations of the Red Cross Society of Japan in its humane treatment of himself and other prisoners This narrative is in effect the involuntary outburst of gratitude of a man who has received kindness and entertainment from a supposed embittered enemy The writer is a naval officer having an American education, Tsoy Chan by name The following is a part of his manuscript

"In the Red Cross Hospital the patients were treated most kindly Plenty of milk and fresh eggs were given Rice, beef, fish, turnips and onions formed the ordinary diet Mr Mesaki was the superintendent of the hospital, and is a most conscientious man Unless on public business, he never left the hospital, and every night he went through the patients' quarters twice The head nurse was Mrs Tanaka, the wife of an officer, and a very energetic lady She was not afraid of work and did many kind acts to relieve the sufferers Ten other nurses were under Mrs Tanaka, all of whom had special duties at regulated times The nurses seemed to have administered to the patients with a sense of religious duty There were two or three Christians among them, the rest, adherents of Buddhism There were two young doctors who never left the hospital unless doing duty in the prisoners' lodge They took turns in the night watches Every morning a senior doctor came to examine the patients Scrupulous cleanliness was kept in the hospital One day an army surgeon, Dr Arima, and the Rev Mr Wada, of Tokyo, visited the hospital and spoke to us most kindly, wishing us a pleasant passage home and a joyful reunion with friends and relatives At the word home, many dropped tears One night we were treated to a magic lantern exhibition The different pictures showed the history of the Red Cross Society, and among the pictures were also those of their Majesties, the Emperor and Empress of Japan The wives of some Japanese officers visited the Red Cross Hospital The first party gave 3 yen to the patients to buy what they liked, the second party gave 7 yen Some handkerchiefs, tobacco and cakes were distributed to each of us in the hospital as souvenirs to take back home It is with an indescribable feeling of sadness and joy that I write this account It is sad to have been made a prisoner of war, but, having been captured, I am glad that it was my good fortune to have been thus kindly treated The total number of prisoners at Osaka, including officers and men, was very nearly three hundred, and all agreed that we were better treated than we had any reason to expect It is usually with reluctance that men speak well of their opponents, but facts like these ought not to be concealed We have a saying in China that kindness received should never be forgotten I have not written this account with the joy and enthusiasm of a sensational novelist, but simply to discharge what I feel to be clearly my duty"

Society Notes

The Tri County Medical Society, at its regular meeting held in Paxton, Ill, November 8, elected the following President, W P Pierce, Hoopestown, Vice-President, T N Bowe, Loda, Treasurer, J Y Campbell——The annual meeting of the Topeka Kan, Academy of Medicine and Surgery was held November 11 The following officers were elected President, M B Ward, Vice-President, W E McVey, Secretary and Treasurer, Ida C Barnes——The annual meeting of the Schuylkill County Medical Association was held in Pottsville, Pa, November 12 The following officers were elected President, A P Carr, St Clair, Vice-President, A F Bronson, Girardville, Secretary and Treasurer, George Little, Tamaqua

Hospital Notes

Frederick Holme Wiggin has been reappointed visiting gynecologist to the New York City Hospital by the Commissioners of Charities and Correction

Post-Graduate Hospital of New York—The Board of Estimate of New York city has made an appropriation of $60,000 in support of the gratuitous hospital and dispensary work done by the above named institution for the year 1896

Hospitals Remembered—Under the will of the late William Stackpole, of Brooklyn, N Y, reversionary interests are conveyed to certain charitable institutions Of these, the St Mary's Hospital and the St Mary's Female Hospital will receive each $1,000

Detroit Notes

Typhoid Fever—A communication dated October 16, has been received by the Health Board of the city of Detroit, from the State Board of Health, stating among other things, the fact, that owing to the prevalence of typhoid fever in Detroit, the disease has spread to other parts of Michigan, and as a result there have been ten outbreaks and three deaths It also requests the Detroit Board to enter vigorously upon the work of notification and restriction of the disease in Detroit On the strength of this communication, Dr Samuel P Duffield, health officer of the city has issued circulars to the nurses and persons in charge of typhoid patients, instructing them to disinfect all discharges as soon as possible, by pouring a quantity of the solution of chlorid of lime or copper sulphate into the bed-pan, and to have the mattresses and other bedding destroyed He also sent a circular to the undertakers, impressing upon them the necessity of carefully and thoroughly washing out the intestine, either with the solution of one half pound blue vitriol and one gallon of water, or two pounds zinc sulphate and one gallon of water, and not to place any reliance on the virtue of the embalming fluid to kill the typhoid germ

Detroit Medical and Library Association—At the last meeting of this Association, October 14, a very interesting paper entitled "Hay Fever, a successful Treatment based on a New Theory," was read by Dr F W Strangways, and discussed ably by Drs E L Shurly, P M Hickery and H J E Emerson

Wayne County Medical Society—At the regular meeting of this society November 14, a very interesting paper on smallpox was read by Dr John F Bennett, it was the more interesting from the fact of the existence of smallpox in Detroit at the present time A number of physicians from Windsor, Ontario, Delray, Highland Park and other surrounding places were present Dr J J Mooney also read a paper entitled "Angio-neurotic Edema"

Personal—Dr N W Webber is now convalescent from his late attack of rheumatism

Mortality Report for the week ending November 16 deaths, 78, under 5 years, 26 Births, male 53, female 35, total 88 Report for week ending November 16, (contagious diseases) diphtheria last report 43, new cases 22, recovered 34, died 6, now sick 25 Scarlet fever last report 11, new cases 6, recovered 4 died none, now sick 13 Smallpox last report 1, new cases 2, recovered none, died none, now sick 3

St. Louis Notes

The Weekly Mortuary Report, gives for the week ending November 16 deaths, 156, compared with 167 during the preceding week, and 165 for the corresponding week of 1894 Births reported, 294 The contagious diseases reported during the week ending November 16, were diphtheria, 126 cases, 10 deaths, croup, 16 cases, 7 deaths, typhoid, 10 cases, 2 deaths, measles, 15 cases, scarlatina, 8 cases

St Louis Medical Society—The program of the meeting of November 16 consisted of a paper on "Tuberculosis of the Knee-joint," by Dr Funkhouser, with prepared discussions by Drs H H Mudd and Pinckney French The general discussion was further maintained by Drs Hoffman, Fairbrother, and Hodgen

Charity Commissioners—At the regular meeting November 11, the supervision of the various city institutions was divided among the commissioners, and hereafter written monthly reports on each institution will be required In future, an effort will be made to prevent the prolonged detention of boys in jail in the contaminating atmosphere of the criminal classes

Provision for Idiots and Imbeciles—There has been some public agitation of late of the question of State provision for this dependent class Such improvements are to be accomplished only after assiduous efforts on the part of those who come in contact with such individuals, and the medical profession should lose no opportunity to show the need of this socially protective charity

Meat Inspection—At the request of the Health Commissioner, a bill has been presented to the Municipal Assembly repealing the present meat inspection ordinance and providing for the thorough inspection of live animals intended for food, also, for the inspection of meats of all kinds, poultry, game, etc, when ordered It provides for the same force of inspectors numerically as now employed, namely, four, one to be a chief inspector at a salary of $150 a month, and three assistants at salaries of $125 a month each Two of these must be practical butchers All must work under the supervision of the Board of Health and each must be secured by a bond of $4,000 for the faithful performance of his duties Accompanying this bill was a statement of the Health Commissioner who explained that he found that the laws respecting meat inspection were very inefficient, that this branch of the service cost the city $5,000 a year, with very meager results, that quantities of meat unfit for food, but the real condition of which was not revealed by inspection, were sold by the butchers, that no check was placed upon the slaughter of diseased animals, also that he had ordered the inspection of meats stopped and placed the inspectors at points where the greater number of animals, intended for food were killed

The St Louis Academy of Medical and Surgical Sciences is the title of a new medical society lately organized The officers are Dr G W Cale James Moores Ball, Arthur E Mink, Emory Lanphear Thomas G Summers, Wellington Adams and George H Thompson It is reported that the membership is to be limited to 50, and that an applicant for membership can gain admission only upon the merit of a thesis submitted

Damage Suit—Dr Carl Barck has successfully defended a suit brought against him for $10 000 damages, by a patient, for the loss of sight The case was clearly one where ignorance on the part of the patient had led to a disastrous result, and to a hope to make the Doctor pay for what he was in nowise responsible One of the patient's eyes had been injured to a degree requiring enucleation, this operation was refused in spite of warning for the safety of the uninjured eye Later, the patient returned for operation, and the doctor performed enucleation, stating at the time that there was great probability that the operation was then too late to save sight in the opposite eye The fulfillment of his prediction was the occasion of the suit

Philadelphia Notes

The Trustees of the University of Pennsylvania have conferred the title of Emeritus Professor of Comparative Anatomy upon Dr Harrison Allen, in acknowledgment of his services to the institution in the chair which he recently resigned bearing a similar title

The Official Statistics of attendance at the University of Pennsylvania show a slight increase over last year The medical department has 819 in all the classes this year Last year the number was 815 The dental department has 306 against 278 last year, hygiene 56 or 15 more than last year, and veterinary medicine has 16 less than last term The total attendance in all departments is 2,472 students The entering class at the Jefferson is small this year on account of the inauguration of the four years course, while the matriculants at the Medico Chirurgical have decidedly increased because the fourth year has not yet been made compulsory

The Cliff Dwellers—The Archæologic Museum of the University of Pennsylvania has been recently greatly enriched by the addition of the valuable Hazzard collection of remains of the cliff dwellers, a great portion of which was one of the most interesting features of the Chicago Exposition The collection was formally thrown open November 9 by an address made by Mr Frank Cushing, who has made a special study, while living among the Zunis, of the primitive races of this continent Prof E D Cope made a few comments upon the physical characteristics of the cliff dwellers, as illustrated by the perfectly preserved skeletons and mummies contained in the collection The skulls were artificially flattened at the back, like those of many other Indian tribes The teeth showed a high type of development, while the hyoid bones and tibias were of a lower type There is nothing in their remains to separate these primitive people from other American Indians all of whom probably originally were of Mongolian derivation The collection of American antiquities in Philadelphia is claimed to be the finest in the world A course of public lectures will be given during the winter by Mr Cushing and Profs D G Brinton and Cope, in the library building of the University of Pennsylvania

Death from Carbolic Acid Accidentally Administered—A child fifteen months of age, died last week, soon after the administration of a teaspoonful of medicine, and the mother's lips also were burned by kissing the child just after the medicine had been given At the inquest it was found that the medicine was a very strong solution of carbolic acid, although the prescription called for only one drop of carbolic acid in a two-ounce mixture of peppermint water and plain water The prescription was given at the dispensary of the Jefferson Medical College Hospital, and the evidence before the coroner appeared to fix the responsibility upon the hospital druggist who, the coroner intimated had made the mistake of omitting the peppermint and dispensing equal parts of carbolic acid and water It was a death from misadventure, but it brings up the question for serious consideration, whether or not the dispensing portion of the service at the out-patient departments of great city hospitals is always on a par with other branches in efficiency and reliability It is probable that the courts will have occasion to pass judgment upon the question of liability for negligence or mistake by the dispensary druggist, especially if the latter be found not to be properly qualified for the duties of prescription clerk

Physiologic Experimentation in the Coroner's Office—The coroner of Philadelphia recently rendered an opinion which claims a place in medical annals A child 5 years of age, was bitten by a dog, alleged to be rabid, and a few weeks later was brought to the Pennsylvania Hospital with symptoms believed to be characteristic of hydrophobia After a short illness of less than three days the case ended fatally and a diagnosis of hydrophobia was made Subsequently, the coronor made an investigation, not because of any suspicion of violence or criminality in connection with the death, but apparently simply on general principles By direction of the coroner, inoculation experiments were made, and as the rabbits survived and did not become rabid, the conclusion was adopted that the child did not have hydrophobia and at the public inquest the coroner accordingly revised the diagnosis of the physicians who had had charge of the case, and who had had an opportunity to study it clinically Here is an instance of the dogmatism of the laboratory, about which clinicians have been warned by Professor Lepine, and of which they are likely to experience more in the future

Philadelphia Home for Incurables—A children's building has been added to the Philadelphia Home for Incurables consisting of a main structure three stories high, having a two story wing on each side, costing $36,474 It is of red mottled brick, with red sandstone trimmings and slate roof, and is fireproof throughout The main structure contains a reading room, matron's room, reception room and hall and sewing room on the first floor, diet kitchen and four rooms for special sickness on the second floor, and the nurses' and servants' quarters on the floor above The west wing contains the dry rooms, dining rooms and school rooms, and in the east wing are the sleeping apartments, where each child may have a separate room

State Pharmaceutical Examining Board—Of the 172 persons examined in Philadelphia by the State Pharmaceutical Examining Board, but 27 succeeded in passing Of these 16 received qualified assistants' certificates and 11 received registered pharmacists' certificates In Pittsburg, 27 out of 108 applicants were passed The next examination will be held in Philadelphia on January 18

Washington Notes

Health of the District—The report of the Health Officer for the week ended November 9 is as follows there was an increase of 5 over the previous week in the total number of deaths reported at the Health Department last week While the mortality from the brain and heart diseases fell from 26 to 6, those from lung maladies increased from 20 to 37 Deaths from typhoid fever decreased from 17 in the preceding week to 8 in the past week There were but 3 deaths from malarial fevers The dangerous contagious and eruptive ailments continue in abeyance, there having been but 2 fatal cases of diphtheria in all There were 97 births reported and 56 marriages Of all the deaths 26 were in hospitals and but 2 from the coroner The whole number of deaths was 121, of which 70 were of white persons and 51 colored

Annual Report of Committee on Public Health—At the meeting of the Board of Trade held on the 11th inst, the annual report of the Committee on Public Health was read and adopted The following are the principal subjects of recommendation made with a view to remedying existing evils 1 The extension of the system of sewerage and the completion and purification of the water supply, including the abolition of pumps and wells and the establishment of a proper system of sedimentation and filtration 2 The enactment of an effective law regulating the sale and supply of milk 3 The establishment of a bacteriologic laboratory in connection with the health department 4 The revision and extension of the sanitary laws and regulations of the District, including the appointment of a committee of five to prepare and formulate a code thereof for presentation to Congress 5 The enactment of a law for compulsory vaccination and revaccination 6 The enactment of a law to regulate the practice of medicine in the District of Columbia The medical men on the Committee are Dr Samuel C Busey, Chairman, Drs G L Magruder and H L E Johnson

The Woman's Clinic —At the annual meeting of the contributors to the Woman's Clinic, held on the 5th inst, the Secretary reported that 3,165 patients had visited the clinic for treatment during the year The following board of directors was elected for the ensuing year Drs D S Lamb, Ida J Heiberger, Mrs Mary F Case Miss Minnie E Heiberger, Drs J H Bryan, S M Burnett, H L E Johnson, Mary Parsons, D W Prentiss, Julia E Smith, Abbe C Tyler, Mrs Cora Dufour, Mrs Marian H Anderson, Mrs Emily L Sherwood, Drs H C Yarrow Robert Reyburn, Mabel Cornish, Miss Satie Hyde, Mrs Walter E Burleigh, Drs Sofie A Nordhoff, Jessie Kappelar, Phebe R Norris, Ada R Thomas, Susan J Squires and Adeline E Portman Mrs Anderson was elected First Vice President, Dr Lamb, Second Vice President, Mrs Mary F Case, Secretary, and Miss Heiberger, Treasurer The clinical staff is as follows Drs Heiberger, Smith, Kappelar Cornish, Nordhoff, Dufour, Norris, Thomas, Portman and Squires

Annual Report of the Sanitary Officer of the District —The report of the sanitary officer shows that during the past year the whole number of persons furnished with transportation was 867, at an expenditure of $1,776 55 Attention is called to the increase of the number of persons sent to the hospitals of the District, the record for the year being 3,559, an increase of 183 over the previous year He renews his former recommendation looking to the establishment of an asylum or hospital for inebriates, where the treatment of such patients should be made compulsory

Microscopical Society Banquet —The twelfth anniversary of the Microscopical Society of Washington was appropriately celebrated on the 12th inst, by a banquet, which proved one of the most enjoyable affairs in the history of the organization The President of the Society, Dr Collins Marshall, presided, and Dr C T Caldwell officiated as toastmaker Toasts were responded to by Drs Marshall, William H Seaman, Robert Reyburn and J Melvin Lamb

Clinical Society Meeting —The Clinical Society of the District of Columbia held its regular monthly meeting Monday evening at Columbia Hospital There was a large attendance Papers were read by Dr Van Ezdorf on "Hydrothenudin," and Dr Louis P Smith on "Retroflexion of the Uterus" The papers were discussed by Drs Barton, Barrie, Lewis, Vale, Smith, Van Ezdorf, and others

Medical Society of the District —At the meeting of the Society held on the 13th inst, Dr Kober read a paper entitled "Impure Milk in Relation to Infantile Mortality" The paper was discussed by Dr Geo M Sternberg, Surgeon-General U S A, Drs de Schweinitz, Carr and others The Southern Surgical and Gynecological Society attended as guests

The Southern Surgical and Gynecological Society —The Southern Surgical and Gynecological Society held its eighth annual meeting during the present week Dr Samuel C Busey President of the Medical Society of the District, delivered an address of welcome on behalf of the local medical men The Washington Obstetrical and Gynecological Society entertained them at a banquet on the 12th inst, and Dr Joseph Taber Johnson gave a reception and banquet at his residence on the 13th inst, after the meeting of the medical society, to which they had been invited Through the courtesy of Mr John T Devine, proprietor of the Shoreham Hotel, the large banquet hall of the house was furnished gratuitously for the use of the society during their session The society has decided to hold its next meeting at Nashville, the second Tuesday in next November, and elected officers for the ensuing year as follows President, E S Lewis, New Orleans, Vice-Presidents, Joseph Taber Johnson, Washington, and Richard Douglas, Nashville, Secretary, W E B Davis, Birmingham, Ala, Treasurer, A M Cartledge, Louisville Council, Geo J Engleman Boston, Hunter McGuire, Richmond, W D Haggard, Nashville, Bedford Brown, Alexandria, and L S McMurtry, Louisville Committee on Arrangements, W D Haggard, Nashville Many new members were admitted to the Association, and a pleasant incident of the day was the receipt of a handsome gavel from Dr H Marion Sims of New York, in memory of his father The gavel has a very unique history or origin It was turned from one of the legs of an old operating table used for many years by J Marion Sims The next meeting will be held the second Tuesday in November, 1896

Dr Henry J Crasson's Marriage —On the 12th inst, at St Peter's Church, Dr Henry J Crasson was married to Miss Margaret Blaine, daughter of Mr and Mrs Robt G Blaine, and niece of the late Hon James G Blaine Dr Crasson was for some time one of the assistant physicians to the Central Dispensary and Emergency Hospital

Circular to Medical Examiners —The Equitable Life Assurance Society of the United States has sent the following circular to its medical examiners

Please take notice that on and after Nov 15, 1895, the following scale of fees for medical examinations will go into effect, in substitution for formerly established rates These will be uniform throughout the United States, the Canadian Provinces, and Newfoundland

Case of application for $8,000 insurance or under	$3 00
Case of application for over $8,000 but less than $25,000	5 00
Case of application for $25,000 or upward, short of $50,000	7 50
Case of application for $50,000 or upward	10 00

By order of the President,
Edward W Lambert, M D,
Medical Director

N B —Installment insurance is reckoned at its commuted value

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from November 9 1895 to November 15, 1895

Capt Eugene L Swift, Asst Surgeon leave of absence granted is extended one month, and he is authorized to go beyond sea

Major Louis W Crampton, Surgeon, is granted leave of absence for three months, to take effect on or about Dec 1 1895

APPOINTMENTS

Thomas Jellis Kirkpatrick, Jr, and John Hamilton Stone, appointed Asst Surgeons with the rank of First Lieut, to rank as such from Nov 6 1895, and ordered to report to the President of the Army Medical School for instruction

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending November 16, 1895

Surgeon T Owens, detached from Naval Station Port Royal, S C, and granted three months' leave

Surgeon J R Waggoner detached from the "Independence," and ordered to the Mare Island Cal Navy Yard

Surgeon George P Bradley, detached from the Mare Island, Cal, Navy Yard and ordered to the "Indiana"

P A Surgeon George Rothganger detached from naval hospital treatment, and ordered to the "Independence"

Surgeon J E Gardner, ordered to Port Royal, S C, Naval Station

Change of Address

Fletcher Wm W from Susquehanna to West Carbondale Pa

Gihon A L from Washington, D C, to United Service Club, 16 W 31st Street New York N Y

Goode, Thos F, from Buffalo Lithia Springs to Boydton Va

Massey G Betton from 212 S 15th Street to 1636 Walnut Street, Philadelphia Pa

Moffitt, F W, from 1269 93d Street, to 4257 Cottage Grove Avenue Chicago Ill

Scholer, L S, from 3 N Clark Street to 1956 N Halsted Street, Chicago Ill

Vincent, Dr, from La Porte Ind, to 811 12 "The Arcade" Cleveland Ohio

Westmoreland W F, from Austell to Atlanta, Ga

ORIGINAL ARTICLES

HYPNOTISM

ITS USES, ABUSES AND MEDICO-LEGAL RELATIONS

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY WILLIAM LEE HOWARD, M D
BALTIMORE, MD

It is with a grateful heart and thankful attitude that I address this Section on some of the aspects of hypnotism After several years of study of this subject in the medical centers of Europe, I found the opportunities here rather inconvenient for anything more than unassisted investigation Two years ago I found myself repeating the words Euripides put into the mouth of Medea

> "For when you bring new truths to men's minds
> They deem you not wise but unpractical,
> While those who on deep learning pride themselves
> Are piqued, and you incur the general hate"

It is not necessary to say more, for science has proved too strong for prejudice

I shall take up the subject by dividing it into four sections

1 Theories and facts
2 Its therapeutic uses
3 Its abuses
4 Its medico-legal relations

The theory of hypnotism I shall touch but little upon, for we have been studying the phenomena for several years, and it is now time to take action on our conclusion of facts as far as we have them As neurologists we have too long been studying the brain, not its functional product—the mind The abuses of hypnotism call for some attention, as they must be shown and predicated before we can take up the juridic side of the case

I do not intend to go into the discussion of the theories of the two schools of hypnotism, but I think we can, by looking at the subject from an elemental basis, get a better understanding of the foundation upon which these superstructural theories have been reared

Whether we take the Charcot or Nancy school, the subject is the same to us from a therapeutic or medico legal point of view Charcot's school agree in regarding hypnotism as an induced neurosis closely allied to hysteria, and therefore pathologic, while the Nancy school refuse to see in hypnotism anything but a psychologic condition almost identical in its nature to natural sleep

Charcot considered hypnosis a distinct entity marked by the presence of certain somatic phenomena while Bernheim denies that there are any technical phenomena characteristic of the condition, and refers everything to suggestion Although a former pupil of Charcot, my investigations have led me to follow the teachings of Bernheim

This idea of suggestion grasped in its full significance, compels us to alter somewhat our old idea of the *ego* In fact, it is questionable if our ordinary conception of it is correct We are accustomed to think of the ego or personality as something *in se ipso totus, teres atque rotundus*, a complete indivisible unity

Recent studies in psychology seem to indicate that the unity of the human consciousness is not one of its functional attributes

To quote Mr Myers[1] "My organism is the real basis of my personality I am still but a colony of cells, and the unconscious or unknowable, from which my thoughts or feelings draw their unity, is below my consciousness and not above it, it is my protoplasmic substructure, not my transcendental goal"

According to this, the self is not a separate entity independent of the organism in which it dwells, and its entity is really a product of its structure So that it is not only consciousness of self but the quality of the particular self that depends on the relations, partly structural, partly relations of adjustment—between the cell or other units which compose the organism Alter these relations and you alter the self These alterations are brought about by suggestion, and this produces the phenomena seen in the various stages of hypnotism

The general impression that hysterical persons are those chiefly amenable to hypnotism is an idea that I must dissent from I have hypnotized patients in Iceland, Africa, China and various other parts of the globe, and have not found that the hysterical element was necessary Furthermore, if only hysterical persons are susceptible we must modify and enlarge our conception of hysteria, or admit that 80 per cent of men and women, and 95 per cent of children are hysterical For nearly all children are hypnotizable, and we rarely find hysteria before puberty Dr Schrenk-Notzing has recently published some international statistics contributed by fifteen observers in nine different countries, and these give 6 per cent of failures in 8,705 cases Wetterstrand of Stockholm, states that the hardest subjects he found to hypnotize were hysterical and nervous persons, especially neurasthenics This has also been my experience Dr J J Bramwell of London,[2] states that he had succeeded in hypnotizing 88 per cent of both sexes, of varying ages and social positions The investigations of the Second International Congress of Experimental Psychology admitted the therapeutic advantage derived from hypnotic suggestion and the recognition of the important fact that the susceptibility to hypnotic control is not itself an indication of hysteria or of any morbid condition whatever in the subject

THE THERAPEUTIC USES OF HYPNOTISM

As regards the therapeutic uses of hypnotism we have been confronted by two divergent tendencies, the one leading to exaggeration the other leading men to disparage or ignore the subject It is scarcely necessary to state that this latter attitude is assumed through a lack of scientific inquiry into the matter These *quid nunes* display a feat of exegetic audacity which would equal that of a Chinese general. I shall try and look at both sides calmly, without undue enthusiasm or prejudice The few facts I shall offer for your consideration will be only those that have come under my observation the past year The literature of the past five years on this subject is so pregnant and rich in facts, and so ponderous in its multiplicity of works, that you are all more or less familiar with the therapeutic uses and limitations of hypnotism to day

[1] Human Personality p 639
Lancet Nov 4 1893

For insomnia I know of no remedy equal to hypnotism Lately, considerable has been said about the use of hypnotism in dipsomania and alcoholism I have found it of great value in these cases, and have been able to cure 85 per cent of my patients When I say cure, I mean those who have gone three years without returning to their old habits I have had one relapse after three years complete abstinence, and one after three years and three months It is useless to try and cure your patients unless you are fully convinced that they honestly desire to be cured With the drug habit I have had about the same good result Bushnell, Surgeon U S A, gives a list of eighteen cases He says "I have never failed to hypnotize a patient who sought treatment for alcoholism

The reason we get such good results in alcoholism and the drug habit is on account of that intellectual inertia consequent upon frequent stimulation, and it is a psychologic fact that a mind thus weakened is more susceptible of receiving and accepting suggestion than one in possession of more stable and mental vigor This is only true where there has been no organic change in the brain tissues Of course this treatment should go hand in hand with the modern hygienic methods now used in institutions throughout the country

I will say here that I do not intend to give histories of cases, as my time is limited and I wish to over the whole ground in a general way

Hypnotism is of value in enuresis nocturna, masturbation in both sexes, acquired but not congenital sexual perversion This is a distinction to which I particularly wish to call your attention

In certain forms of hysteria which baffle all other methods of treatment, hypnotism is invaluable Pope,[4] reports a case of hysterical alexia cured by hynotism I have cured cases of hysterical contractures that had been the rounds of the hospitals Daland also reports similar results[5] Dr Eugene Reveielva[6] reports a case of hysterical paraplegia cured by suggestion I have had one case of paralysis agitans,[7] in which the movements were arrested during suggestive sleep, thereby giving the patient much needed rest Barretto Pisquer, Bahia, Brazil,[8] gives several cases of hysteria cured by hypnotism I think that we can lay down the rule that hypnotism will invariably remove hysterical symptoms if not hysteria itself While these facts may appear contradictory to my former statement that hysterical persons were the hardest subjects to hypnotize, you will remember that I did not say that they could not be hypnotized They require greater persistence on the part of the operator, and your efforts will often prove fruitless Mental excitement greatly militates against hypnosis[9] I have had many failures due to this condition

In cases of epilepsy, I think that too much importance has been attached to suggestion and not enough to artificially induced sleep Especially is this so in anemia and chlorosis Berillon reports a cure of four out of twenty epileptics, in six other cases the attacks were greatly modified In a young woman of 25 years, an aphasia of three years standing was completely cured I am far from believing that persons with inveterate hystero epileptic fits can be cured by anesthetizing hysterogenic zones or by stopping these sleeping periods by hypnotizing and suggesting at the same time But since the outbreak of inveterate fits is preceded by a period more favorable to our therapeutic operations, the experiment of leading the disease into other channels during these periods seems to me worthy of trial Wetterstrand is now keeping those patients in a prolonged sleep lasting several months I believe here we are on the right track You can suggest intervals of awakening and hunger I kept one patient who was having five fits a day free from them for ten days, during which she was in an artificially induced sleep I feel certain that I could have greatly benefited her if not cured her, had I been allowed to continue the sleep for several months But church, meddling friends, and superstitious family were too strong for me

Babanski,[10] relates a case of left, hemiplegia, with hemianesthesia dating from an attack of year before. The patient had a post hemiplegic lateral tremor simulating insular sclerosis, contracture of the left leg and arm, and exaggerated reflexes He suffered from dyspnea dependent on emphysema Hypnotic suggestion caused a rapid cessation of the tremor, relaxation of the contractures, return of the common and painful sensations to the left side, return of the power to stand and walk without a stick and with very little dragging of the limb

The amelioration of all the symptoms continued for two years, during which time the man was kept in the hospital and occasionally hypnotized He died at the expiration of two years The autopsy revealed foci of yellow softening in both hemispheres, upon the convexity of the left occipital, and in the right hemisphere immediately behind the posterior extremity of the optic thalamus Almost all the posterior portion of the external segment of the corpus striatum was destroyed, and its cavity filled with fluid The medulla, pons medulla, and cord were not implicated, nor was there any degeneration of the pyramidal tract

Bernheim in commenting on this case, suggests the possibility of suggestion having reestablished the conductivity of sensory impressions of other tracts in place of those destroyed, but Babanski considers tha hypnotic suggestion simply affected the hysterica element of the case The fact, however, remains tha a man suffering from a grave organic disease of th brain was very greatly benefited by suggestion an enabled to walk long distances and feed himself fo two years, after he had been unable to do so for mor

than a year Several cases have been reported from Europe in which the symptoms of locomotor ataxia have been greatly warped by suggestion

We are all familiar with the fact that local and complete anesthesia can be produced in hypnotic subjects, and minor as well as major operations done with greater facility and less danger than with chemic aids That hypnotism will ever take the place of our present anesthetics is very doubtful, as this stage of mental suggestion can not always be effected at the time wanted, however, I have used it frequently in cases where I had the time to thoroughly develop the subject, and often in an emergency I believe that we are doing an injustice in giving the anesthetics without first attempting to produce an anesthetic condition by hypnotic suggestion In dentistry, for the extraction of teeth, I have used it several times at the request of the dentists It is a safe, neat and very satisfactory method of painlessly extracting teeth But the *zeno genesis* can only be produced by one who has the confidence which comes from experience

Professor Hitzig[11] produced anesthesia in the whole forearm for painful scars, the effect of such suggestion done but once lasting several months Prodromal headaches in certain cases can be relieved by hypnotic suggestion In labor cases it is best to hypnotize your patient once or twice before labor begins I prefer to begin several days before the expected occurrence, because when labor begins the condition of suggestibility decreases on account of other sensations intervening A large number of observers, especially Schrenck-Notzing, report successful cases of confinement by hypnotic suggestion The advantages of hypnosis in labor are the removal of consciousness of pain, regulation of position of limbs, body and attitude, and increase or diminution of uterine contraction by action of voluntary muscles under suggestion

In persistent hiccough that sometimes baffles all other treatment, I advise you to try hypnotism In a case of four days' persistent hiccoughing I gave immediate relief Dr Fitzgerald, of the City Hospital, St Louis, had a similar result in a case of an old man who had been hiccoughing for forty eight hours and who was in a very low condition

In a large number of cases it is not necessary to produce complete hypnosis to get satisfactory therapeutic results If you have hypnotized the patient several times, if even he has only been in a state of lucid lethargy, he will often take suggestions satisfactorily in a waking state Deep sleep is not necessary for suggestions to take effect There are also persons so amenable to suggestion that hypnosis is unnecessary, this is especially the case with children In other persons, suggestions must be adapted to the condition of the patient, to his mental individuality, and to the special symptoms to be removed

I have been unable to see any decided beneficial effects in the hypnotization of the general insane In fact, it is almost an impossibility to endorm these cases Idiots particularly, are almost invariably incapable of being brought to that condition of mental attention which is necessary to produce a hypnotic state In those children who are morally perverted by environment and acquirement, mental suggestion is the proper treatment In fact, in these cases we have in hypnotism a basis for a mental and moral orthopedia The only authority who credits hypnotism as of value in the treatment of the insane is August Voisin, but as his statistics only show 10 per cent of cases benefited, it is scarcely worth placing much confidence in this therapeutic method Dr George M Robinson, of the Royal Edinburgh Insane Asylum, has used it with success in insomnia, as a sedative in excitement, as a substitute for restraint, and to dispel fleeting delusional states and the minor psychoses

Therapeutically, suggestion is of value in evolving isolated disturbances in the organ of mind, the cerebral cortex to be acted upon, apart from the symptoms of disease which may be associated with them

THE ABUSES AND DANGERS OF HYPNOTISM

The first danger that I wish to call your attention to, is one that directly interests ourselves That is, in receiving statements of hypnotic subjects we should constantly bear in mind the great risk of conscious and unconscious deception We must have some diagnostic data to rely upon to show the paralyses produced by hypnotic suggestion These facts must be known by the legal as well as the medical profession I give you these facts as laid down by P Richer and Gilles de la Tourette Complete laxity of limbs considerable exaggeration of the tendon reflexes, spinal trepidation, loss of muscular sense, exaggeration and modification of the muscular contraction provoked by the galvanic current, and vasomotor troubles I have generally found a fibrillary motion of the eyelids Jolly[12] gives three cases of mental derangement treated by hypnotism whose conditions were made temporarily worse by the treatment that is, they all showed symptoms of true hysteria which they had not before I have had one case that I feel certain was mentally injured by hypnotism, but it was the manner in which he was treated rather than the effects of hypnotism *per se* He was a subject that was like a piece of clay in my hands and a case that taught me many a valuable lesson I sent him to steal Dr Brinton's watch This he did most adroitly I brought him out of the hypnotic state, when he was accused by Dr Brinton of having his watch When the watch was found upon him the shock was so great that he immediately went into a cataleptic condition With great difficulty I brought him out of it These fits continued almost every hour for several days until I was enabled to hypnotize him and make the post hypnotic suggestion that he would forget all that had happened I have never hypnotized persons for experiment since, without giving them a post-hypnotic suggestion I claim that the injurious effects of hypnotism depend upon the nature of the suggestion, that we are enabled to benefit or injure the mind according to the cortical centers we inhibit or stimulate I will read you a letter I received a few days ago

NEW YORK, March 26, 1895

Dear Sir —About six weeks ago I was partially hypnotized by a person from whom I was taking lessons Since that time I have suffered from an oppressive feeling of weight on my brain, and such drowsiness and loss of interest in things about me that I am forced to think that this unusual condition was produced by the hypnotist especially as I first felt it immediately after the act Please let me know whether I am probably right in my opinion as to the cause of my suffering and give me the address of some reputable physician here, competent to diagnose my case and afford me relief

Yours, etc, ———

---

[11] Brain 1893

[12] Arch für Psychiatrie xxv p 3

A Tuckey[13] mentions a case of complete cessation of respiration by hypnotic suggestion Recourse was had to artificial respiration Heidenhain[14] believes that a healthy person might be placed in jeopardy by continued suggestion to cease breathing I have frequently brought the respiration down to eight a minute, and run the heart beats up to 190 I only ceased the experiment for fear of disastrous results One could find no easier way of committing murder The cause of death could not be detected

We have one well authenticated death by hypnotic suggestion Ella von Salmon died under circumstances pointing strongly to hypnotism as the chief if not the sole lethal agency in her case[15]

The autopsy on this case was conducted in the Pathologic Institute at Buda Pesth in the presence of Dr Jozas and several other physicians The brain exhibited a high degree of anemia and consecutive malnutrition, with indications of edema, otherwise there was no abnormality Dr Jozas considers the cause of death, acute anemia of the brain, incident to the hypnotic state, with syncope and heart failure The experiment with her was of a startling and highly sensational nature While in the hallucinatory state she saw by suggestion a diseased lung, and gave a long description of the pathologic condition in an excited and agitated manner The final question of the operator had an intense emotional effect on her, and caused her collapse She did not die from auto- or imparted suggestion, causes which might prove fatal under certain circumstances In commenting on this case Kraft-Ebbing says "The question of the cause of death in this case probably permits this answer The unskillful use of hypnotism by a layman and the unusually violent cerebral excitement stand as the causes of death" This case teaches us that the laity should not practice hypnotism This naturally brings us to the consideration of the medico-legal aspects of hypnotism

THE MEDICO-LEGAL ASPECTS OF HYPNOTISM

We now come to the juridic aspect, and this opens such broad possibilities, such intricate problems, and in our present state of knowledge of the subject, such a bewildering maze of contradictions, opportunities, and incongruities that I approach the matter with hesitancy To even approach the threshold of this side of hypnotism with as few words as possible is no easy task However, I will attempt in five minutes to give you the kernel of my thoughts and study on the matter

I think that I can say without the fear of contradiction that we all agree that laws should be enacted in this country regulating the practice of hypnotism Such laws, and stringent ones too, exist to day in most civilized communities All public demonstrations of hypnotism should be suppressed by legal action, and the courts take cognizance of citizens being subjugated by any unqualified experimenter, as it does of the unlawful practice of drug prescribing or surgical operations by unqualified and unlegalized persons The trail of hysteria, auto-hypnotism and neurotic eruptions that is left in the towns visited by the traveling mesmerist can only be understood by one watching the route of these pseudo-scientific men This was well illustrated in the Briggs-Picken case at Eau Claire this winter Two young girls who had been subjects of a traveling hypnotizer were finally wrought up to such a condition of hysterical autohypnosis as to accuse Dr Picken of seduction under hypnotic control Judge Wm F Bailey very justly decided to get some information upon hypnotism before allowing the plea of hypnotism to be entered The case being laid before me, I soon satisfied myself that there was no basis upon which to enter such a plea I concluded that the simulation was objective That the case was one of auto suggestive self-deception The wanton and unscientific hypnotic suggestions which had been given them for several days produced in these girls a condition in which they gave statements of erotic auto suggestion, delusion of memory, delusion of sight, and gaps in their life's history

In the Anderson-McDonald case just decided by the Supreme Court of Kansas, wherein the hypnotized or automatic murderer was acquitted and the hypnotizer sentenced to death, we had the first case of the kind in this country, but you are all familiar with several cases of the kind decided by the courts in Europe One error seems universally prevalent among both the laymen and the profession who have criticised this decision Because the hypnotizer was not present when the act was committed, the opinion is expressed that the person committing the act was not hypnotized This is a grave error, and the court should be made familiar with the greatest danger hypnotism presents I refer to the post-hypnotic condition By post-hypnotic condition I refer to the appearance of a hallucination at a given day and hour or the performance of a suggested action after a certain interval of time during which interval the subject is in his normal mental condition This is the only scientific explanation of the idea of transference of suggestion through space There is no such phenomenon known to the accurate psychic observer. There must be verbal or ocular suggestion, as sending a note to the subject which commands him to perform certain specific acts In those cases of murder where hypnotism is proven, and the hypnotizer is absent when the act is committed, this post hypnotic condition must be seriously considered These post-hypnotic suggestions are given when the subject is in a state of complete hypnosis, but he will after an interval of time, during which he is in his normal state, carry out the suggestions which have been given him, totally unable to explain his reasons for so doing, and carrying them out in all gradients from credulity to extreme hallucinations, all depending upon the purport of the suggestion The recrudescence will occur several weeks after the suggestions have been given.

That crime can be committed through hypnotic suggestion, I am fully convinced I do not base my conviction on the results of the well known laboratory experiments but upon more practical and satisfactory evidence[16]

Under certain circumstances there is no reason why the court can not require an examination of the accused and witnesses by qualified hypnotists *Salus populi suprema est lex* Evidence thus obtained, however, should be used only as indicating where legally usable and valid evidence might be obtained, and not itself legally usable and valid Such cases should if possible be tried before a judge not a jury This is possible in the countries in Europe where the laws differ radically in some respects from those extant here

[16] See N Y Med Jour, March 9, 1895

Hypnotism is a justifiable inquisitorial agent for finding clues In Indianapolis, last January, Frank Pierce and George Schoppe were both arrested and convicted on evidence given by young Schoppe while in a state of hypnotism Dr Gardener, of Napa California Insane Asylum, was called into court last November to hypnotize the murderer Livernash, and succeeded in getting the truth from him I might continue by quoting a large number of similar cases in Europe, but these are sufficient for my case

The law in Holland allows the subjection of the accused to the process of hypnotization to obtain evidence, but such evidence thus obtained can not be made use of unless otherwise corroborated [17]

In discussing the question from the standpoint of criminal law we are confronted by two great questions 1, the responsibility of the hypnotizer, 2, the responsibility of the hypnotized

To the first question the answer is very simple The hypnotizer occupies a position akin to that of an accessory before the fact, who, under the common law of England is equally guilty with, and is punished as a principal, but in the case of a crime committed by one under hypnotic suggestion, the guilt of the hypnotizer is increased In the case of principal and accessory, there are two wills acting in unison, but in the other, the will of the hypnotizer stands alone in the guilt, and if the crime was murder, his position is precisely that of one who lets loose a wild animal upon his victim, knowing that the nature of the animal is such that he will surely kill

From what I have said on the first question, it follows as a corollary to the proposition that the second question is answered by saying that the responsibility of the hypnotized is no greater than that of one who is *non compos mentis*, but this broad generalization requires to be somewhat qualified, and in this connection I desire to note a dissent from Albert Hall in his sweeping condemnation of the view of Desjardins, "that a person who commits a crime by post-hypnotic suggestion is punishable, because he might have foreseen the possibility of such suggestion "

This language is, from a legal standpoint, objectionable, in that it is vague and liable to misconstruction, but with certain qualifications it can, I think, be fairly indorsed If the party hypnotized knew previously that the hypnotizer had this power and was a man of criminal habits and inclinations, and that he himself was subject to hypnotic influence, and yet, while in full possession of his will, he placed himself in such a position as to be within the scope of hypnotic influence, I am strongly of opinion that a certain degree of legal responsibility attaches to him for any crime he may commit, either under the influence of hypnotic or post-hypnotic suggestion, though to what extent he should be punished I am not prepared to say, but his position might be fairly held somewhat analogous to that of an engineer by whose carelessness a passenger was killed—the absence of criminal intent being the same in either case If the one hypnotized had caused the criminal act to be suggested to him, the guilt of both parties would be equal

Now, having fixed the status of the hypnotizer and hypnotized before the criminal law as to their respective resposibilities, we come to what I regard as the most difficult problem to solve how is it to be demonstrated that a given crime was committed by a prisoner while in a state of hypnosis? Such claims are now frequently being brought before our courts. Such a defense may rightly be interposed, and while evidence might properly be introduced in a homicidal case to show that the prisoner had no motive to kill the deceased, but that A had such a motive, and that A possessed the hypnotic power, and that the prisoner was subject to hypnotic influence, and while such evidence might raise in the minds of the jury such reasonable doubt that they would be forced to acquit the prisoner, yet, when the picture is reversed, and we see A placed at the bar, the prosecution is beset with such difficulties under the rules of evidence that I do not consider that it would be competent for it to prove the responsibility of A, by showing that he had exercised the hypnotic power over B at other times, any more than it would be competent for it to prove the guilt of a prisoner by showing that he had been guilty of similar offenses at other times, which evidence is always inadmissable except in rebuttal, where the defense has offered in chief evidence tending to show the previous good character of the accused, and while such evidence would undoubtedly tend to carry moral conviction, it would nevertheless be legally inadmissable The law deals, particularly in its criminal jurisdiction, with facts, not probabilities, and the evidence must be confined to showing that in committing the crime the one striking the fatal blow was acting under either hypnotic or post-hypnotic suggestion, and that the prisoner was the actual hypnotizer, and, ergo, responsible

Another point which occurs to me is the difficulty which might well arise from the trouble in getting the person hypnotized to testify in the presence of the prisoner Might he not, by the exercise of his power over the witness, prevent him from testifying, or render his testimony worthless? Yet it would not be possible to remove the prisoner and then examine the witness, for by the inexorable rule of the common law, every man is entitled to be confronted by the witnesses against him, and no trial can go on in the absence of the prisoner, so that if the prisoner escapes during the trial of the cause, the trial must stop—the common law knowing nothing of any such proceeding as a trial in contumation

It is evident that some radical changes must be made in our criminal procedure in cases where hypnotism is alleged I think a point has been reached where scientific investigation, traveling on well-defined and incised lines, has brought out facts that now allow some regulation of hypnotism by a change of laws The future of the subject should now be confined to those whose training and predilections best fit them to continue research, and properly instruct physician and student Such prerequisites are absolutely necessary to place the phenomena on a dignified platform with nerve physiology Medical schools should be able to furnish instruction to their students in this rapidly developing branch of medicine, for, as Kraft-Ebbing says "Hypnotism as a biologic phenomenon of nature offers symptoms emphatically true, clear and objective, the proof of which is decisive "

DUPLEX PERSONALITY—ITS RELATION TO HYPNOTISM AND TO LUCIDITY

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md May 7-10 1895

BY R OSGOOD MASON, A M , M D

NEW YORK

After a hundred years of obloquy, hypnotism, with some of its most important phenomena, stands to-day an accepted fact Telepathy may be looked upon with suspicion, clairvoyance may be suffering in reputation from contact with charlatanry, but the simple hypnotic state with its conditions of lethargy, catalepsy and somnambulism, has passed from the region of doubt and hypothesis to that of a fact in mental science It is comparatively a newcomer in the scientific world As a wanderer—an Ishmaelite of unrecognized pedigree and doubtful reputation, it has long been heard of, but no one felt bound, and few felt inclined to make its acquaintance, but now with godfathers and sponsors of the highest respectability in the scientific world, it stands upon its rights and demands place and consideration It is no pigmy nor weakling, this newcomer, it has thriven and grown lusty on thorns and stripes, and now it stands sturdily and unabashed in the presence of the representatives of wisdom and with dignity sets forth its claims

And first, with slight respect for its modern sponsors, it claims for itself an honorable lineage, so ancient that its record is found in the very earliest literature and upon the earliest monuments It counseled kings, instructed the wise, swayed the fortunes of armies, enterprises and empires thousands of years before modern science was born Its origin and offices were then reckoned as divine, and its characteristic condition was named the "Sacred Sleep," in which the gods communed with mortals

Admitted as a legitimate member, to the brotherhood of science, its claims to consideration are both practical and philosophical As a therapeutic agent, as a hypnotic and anesthetic, as a stimulant to weakened or diseased organs or functions, as a reclaimer and deterrent from inebriety and crime, as a corrector of the wayward, a spur and educator to the feeble intellect and a dispeller of clouds from the obscured and wandering mind, no other single agent at our command can be compared with it On the other hand, from the higher or philosophical aspect, it is the key to many mysterious, and, by the old psychology, inexplicable conditions or functions of the mind Chief among these unusual states are *double* or *multiplex personality* and *lucidity* or *clairvoyance*, and it is to these conditions that I would especially invite your attention

Not until within the past decade has the subject of duplex or multiplex personality been intelligently examined Indeed, the idea even, of such a condition in any definite form is of very recent date The philosopher Reid, a hundred years ago, wrote as follows "My thoughts and actions and feelings change every moment, they have no continued but a successive existence, but that self, or I, to which they belong, is permanent The identity of a person is perfect, it admits of no degrees and is not divisible into parts," and while this statement may still express the general consensus of mankind upon the subject, and may in a certain sense be well founded, still certain facts have been observed since that philosopher wrote, which bear strongly upon the subject and are entirely rebellious and refractory to the law which he has enunciated

The case of Félida X , reported by Dr Azam of Bordeaux, is one of the earliest to attract the serious attention of students It is classic upon the subject, and may be briefly stated as follows As a child she was sickly, moody and hysterical At the age of 14 years, after a prolonged attack of an epileptiform character, she emerged into a new and entirely unusual condition Her general appearance was changed, and she talked and acted in a manner quite different from her usual self These attacks were repeated and became frequent, and the condition lasted for hours and even days together In her usual state she had no recollection and no knowledge of her second condition or what occurred in it, and the whole time spent in that condition was to her a blank On the other hand, all the different occasions when she had been in this second condition were linked together, constituting a distinct chain of memories, and a personality just as consciously distinct and conspicuous as her original self

The two personalities were entirely different in character and disposition, the original one being sickly, indolent and melancholy, while the new one was in good health, cheerful and industrious, perfectly sane and in harmony with her environments

The second self at length came to occupy the greater portion of the time and to consider herself the chief personality She married, brought up children and carried on the little business of a shop, all in an efficient and exemplary manner She knew the original self, but at first not as in any way connected with herself, but simply as another person and indeed one whom she disliked and dreaded Later she became acquainted with the peculiar relations which existed, and letters passed between the two personalities relating to their common interests, just as they might pass between two separate individuals This condition existed many years, and so far as I know still exists

A second case is that of the Rev Ansel Bourne of Rhode Island, an evangelist and farmer He left his home in Rhode Island Jan 17, 1887, and after transacting some business in Providence he went to Boston, then to New York, then to Philadelphia and finally to Norristown, Pennsylvania, where he opened a store for the sale of confectionery, stationery and other small articles

In this business he was known as A J Brown He lived in a room at the back of the store, cooking, eating and sleeping there He went back and forth to Philadelphia for goods to keep up his stock, and conducted his business as if he were accustomed to it On Sunday, March 13, he went to church and at night went to bed as usual On Monday, about 5 o'clock in the morning, he awoke and found himself in what seemed to him to be an entirely new and strange place He could not imagine how he came to be there, but thought he must have broken into the place in his sleep He waited impatiently for two hours, all the time fearing arrest, and then began to explore his surroundings He went out into the hall and seeing a door he knocked and was answered by his landlord who accosted him familiarly with, 'Good morning, Mr Brown" "Where am I?" he replied, 'My name is not Brown" He declared that he knew nothing of Norristown nor of the stationery business, that he was in Providence on January 17, which he supposed was the day previous, and saw the Adams Express wagons on Dorrance Street, and since that time he had no idea what had transpired The landlord thought he had suddenly become insane and he called a physician To the physician he said his name was Ansel Bourne and that he lived in Rhode Island, that the people in whose house he found himself declared that he had been living with them six weeks, for his part, he had never seen one of them until this morning

His friends were notified, they came on and settled his affairs, and A J Brown went back to Rhode Island and resumed his occupation there as Ansel Bourne, but of A J Brown, of his journey to Norristown, and of the business which he carried on there, he had not the slightest knowledge

Dr Richard Hodgson, Secretary of the Society for Psychical Research, and Professor James of Harvard College, now became interested in the case, they went to see Ansel Bourne and learned the particulars of his strange experience, but of the journey from Providence to Norristown no information whatever could be obtained At length Ansel Bourne was put into the hypnotic condition, when he was again A J Brown He then remembered all about his business at Norristown, and described minutely the journey from Providence to Boston, New York Philadelphia and then to Norristown giving the names of the hotels at which he stopped and the people whom he met—all of which was subsequently carefully verified He thought he had met Ansel Bourne, but had never known him intimately, and when introduced to the wife of Ansel Bourne while he thought possibly he might have met her, he very strongly repudiated the idea that sue was or ever had been *his* wife On being awakened from the hypnotic sleep he was again Ansel Bourne with all his usual feelings, opinions and affections, but had not the slightest knowledge of A J Brown, nor of the business he carried on at Norristown and certainly of any good or evil deed which A J Brown might have done, he, Ansel Bourne was absolutely ignorant and not in any manner to be held responsible

I have myself reported two cases of double or multiplex personality One is that of Alma Z in the *Journal of Nervous and Mental Disease* for September, 1893, the other that of M M, read before the New York Academy of Medicine Oct 12, 1888, and published in the *Journal of the London Society for Psychical Research* for December, 1894 An outline of the former case is as follows

Alma Z was an unusually healthy and intellectual girl, a strong and attractive character a leading spirit in whatever she undertook whether in study sport or society From overwork in school, and overtaxed strength in a case of sickness at home, her health was completely broken down and after two years of great suffering suddenly a second personality appeared In a peculiar child-like and Indian like dialect she announced herself as 'Twoey" and that she had come to help "Number One" in her suffering The condition of 'Number One" was at this time most deplorable, there was great pain, extreme debility, frequent attacks of syncope, insomnia, and a mercurial stomatitis which had been kept up for months by way of medical treatment and which rendered it nearly impossible to take nourishment in any form Twoey" was vivacious and cheerful, full of quaint and witty talk, never lost consciousness and could take abundant nourishment which she declared she *must* do for the sake of 'Number One" Her talk was most quaint and fascinating, but without a trace of the acquired knowledge of the primary personality She gave frequent evidence of supranormal intelligence regarding events transpiring in the neighborhood It was at this time that the case came under my observation and has remained so for the past ten years Four years later under depressing circumstances, a third personality made its appearance and announced itself as 'The Boy" This personality was entirely distinct and different from either of the others It remained the chief alternating personality for four years, when 'Twoey" again returned

All these personalities, though absolutely different and characteristic were delightful each in its own way, and "Twoey" especially was and still is, the delight of the friends who are permitted to know her, whenever she makes her appearance and this is always at times of unusual fatigue mental excitement or prostration, then she comes and remains days at a time The original self retains her superiority when she is present and the others are always perfectly devoted to her interest and comfort "Number One" has no personal knowledge of either of the other personalities but she knows them well, and especially 'Twoey" from the report of others and from characteristic letters which are often received from her and Number One" greatly enjoys the spicy witty and often useful messages which come to her through these letters and the report of friends

Here are three cases in which a second personality—perfectly sane, thoroughly practical and perfectly in touch and harmony with its surroundings, came to the surface, so to speak, and assumed absolute control of the physical organization for long periods of time together During the stay of the second personality the primary or original self was entirely blotted out, and the time so occupied was a blank In neither of the cases described had the primary self any knowledge of the second personality, except from the report of others or letters from the second self, left where they could be found on the return of the primary self to consciousness The second personality on the other hand, in each case, knew of the primary self, but only as another person—never as forming a part of, or in any way belonging to their own personalities In the case of both Félida X and Alma Z, there was always immediate and marked improvement in the physical condition when the second personality made its appearance Several other well authenticated cases are on record showing the same or a corresponding series of phenomena

These phenomena are altogether too marked and uniform not to have a *meaning*, and not to be influenced by some common law or bond, they are no psychologic comets wandering off into space, or in orbits which it is impossible to determine, they must belong to some system, governed by laws which it is possible to study and determine, and it is important to examine closely the psychologic firmament and study the phenomena there discoverable in order to gain what light and aid we may in determining the law by which they are all governed The first series of phenomena presenting analogies with those we have already examined is that connected with somnambulism, and here the analogies are most striking As in the cases above described so in ordinary somnambulism, first, the primary consciousness is blotted out—in sleep, second, another consciousness or personality takes control of the physical organization Third, the different occasions upon which the somnambulist walks or performs his physical or mental work are linked together in one common chain of memories—that which he thinks and does to night is generally a continuation of the thoughts, scenes and events of last night or the last attack of somnambulism—altogether constituting the action of a personality just as consciously distinct as the personalities already described, only of short duration Evidently here is another planet of the same system, revolving in a similar orbit and governed by the same central influence

Looking again, we come upon the interesting and now well known case of Madame B, observed by M. Pierre Janet, of Havre, and Dr Gibert, also a leading physician of the same city, and reported in the *Revue Philosophique* for March, 1888 It presents a remarkable instance of distinct personalities brought into action by means of hypnotism A brief resumé seems necessary

In her ordinary state Madame B is a stolid ignorant, but substantial and honest French peasant woman about 45 years of age—very modest and retiring and without the slightest desire for notoriety In this ordinary state M Janet calls her Léonie Hypnotized Léonie is at once changed into a youthful, vivacious mischief-loving and rather noisy personality who considers herself on familiar terms with the doctors banters and jokes with them and whom M Janet names Léontine Later and by further hypnotization and a deeper trance there appears a sedate personality—intellectually much superior to Léonie and much more dignified and sensible than the vivacious Léontine—and this third personality M Janet calls Léonore

Madame B the original or primary self, knows nothing whatever of either Léontine or Léonore and the time they occupy is to her a blank Léontine, however, knows Léonie the original Madame B, very well and is anxious not to be confounded with her She always calls her ' the other one" and laughs at her stupidity She says ' That good woman is not I She is too stupid" Léonore, the third personality, knows both Léonie and Léontine, and is equally anxious not to be mistaken for either of them Speaking to

M Janet of Léontine, she says "You see well enough that I am not that prattler, that madcap, we do not resemble each other in the least"

Madame B is married, but Léontine is not, but at her accouchement Madame B was hypnotized, and so Léontine was present, consequently Léontine has two children of whom she is very fond, and she would be very much hurt if her right of motherhood were questioned

It is evident that we have here still another planet in our system, moving in a similar orbit and guided by the same central influence as those already examined What is this central idea which dominates the phenomena that we have been considering?

We find a certain definite series of phenomena presenting themselves under three distinct conditions

1 A change from the ordinary or primary condition to a second and entirely different condition, brought about by illness or other physical causes

2 The same change of condition occurring in ordinary sleep and known as sleep walking or somnambulism

3 The same changes brought about experimentally by means of hypnotism—as in the case of Madame B and also that of Ansel Bourne

Of each of these three conditions, under which this change occurs, I have had well marked examples under my own observation, and I have carefully examined the literature of other reported cases, and they all present the same essential characteristics The cases are now too numerous and the phenomena exhibited are too distinct and in too perfect agreement to allow of reasonable doubt regarding the facts themselves, or of their *identity* under all these different circumstances The phenomena which are present in each case are such as to indicate the appearance of an entirely new and independent personality The thoughts, actions, feelings, opinions and even the facial expression and essential character of the second personality are utterly different from those of the primary self Such a marked change occurred in the case of Félida X, of Ansel Bourne, and Alma Z, it also occurs in many cases of somnambulism and also when the change is brought about by hypnotism The statement of all these second personalities themselves so far as it goes, corroborates the same inference The primary personality knows nothing of the second or succeeding ones The second personality in every case declares its absolute independence, is anxious not to be confounded with the primary self, and gives good and substantial reasons for that desire

Again, the submerged second personality sometimes shows its power to act independently, while the primary self is also in full and conscious activity This power was shown in the case of Alma Z and also in M Janet's subject, Madame B

Such are the facts What is the theory which best coordinates them?

I am fully aware of the infinite scorn with which the school of physiologic psychologists look upon experimental psychology, and upon any theory in psychology which is not based in physiology, but when Carpenter, the apostle of that school, could offer no better theory to explain a coherent message automatically spoken or written, than "unconscious cerebration" and "unconscious muscular action," and when Wundt, its latest expositor, teaches that the usual cause of dreams is indigestion, that sleep-walking like dreaming "has no mystery about it," that "the popular belief in premonitions by dreams we need not stop to consider," and that "such superstitions as telepathy and clairvoyance are not even open questions," we know that we are seeking explanations from men who accept or reject facts according to the influence they may have upon their own theories, and that they are useless as guides in this region because they have never themselves traversed it

A theory is only a view taken by the mind in its efforts at an explanation, and it is valuable only as it coordinates and brings into a harmonious system the facts under consideration It is evident that no theory of "unconscious cerebration" can cover the facts in the case of Ansel Bourne, where a perfectly conscious personality, unknown to Ansel Bourne, for six weeks carried on a business with which he, Ansel Bourne, was totally unacquainted, and carried it on in a perfectly sane, consistent and business like manner The facts will not come into line nor harmony under any such theory The theory of an entirely foreign personality carries us far afield and we do not find any necessity for accepting it, even allowing it to be sufficient Of the two theories we must choose the one most reasonable and in best accord with already known facts

The theory of a subliminal self or double personality covers and includes not only all the facts which we have examined, but many others equally inexplicable by the old psychology

Accepting then, provisionally at least, the theory of a subliminal self, without discussing the various questions which might arise regarding its origin, constitution, and its degree of independence of the primary personality—matters which alone would require a volume, let us glance for a moment at other ways in which it is manifested and consider any new or enlarged faculties which it may possess

Somnambulism has already been referred to as a condition in which the subliminal self is the ruling personality and in which the body acts under the control of the subliminal intelligence, but the subliminal self is also often present in sleep when the body is passive, and in that condition we have *dreams*

This is not the time nor place to discuss the general subject of dreams, intensely interesting as that subject is, but we are seeking further conditions and instances in which there is evidently mental action which is shut off from the primary intelligence and corresponds to the conditions already examined Such a condition is, sometimes at least, presented in ordinary sleep and the dreams which accompany it Allow me to describe a case under my own observation

L M, 35 years old, unmarried, has been my patient for the past fifteen years and has been a somnambulist from childhood She is also psychometric, possessing the faculty of perceiving the character and surroundings of those with whom she comes in contact, also when entering a room where persons are sick, she is strongly impressed regarding the result of the sickness These impressions do not come at her desire, but absolutely independent of it, and often in direct opposition to it, sometimes they are extremely vivid, amounting to visual perceptions, and then they seldom fail of being correct She has always considered this faculty a great nuisance, and whenever she has made known these impressions she has been ridiculed by her family Her dreams are equally vivid, true and sometimes prophetic The more vivid ones she does not call dreams, but says "When I *dream*, I *dream*, and when I *see*, I *see*" The following is one of her vivid dreams

She had a friend in one of the principal towns of the Rocky Mountains—a region which she had never visited, and of this man's surroundings she knew absolutely nothing

> One night she dreamed of, or as she expresses it *saw* this man in a room in the town where she knew he was living With him was another person of very marked appearance whom she minutely described She also described the room, its furniture, the bed, the matting upon the floor, the situation of the two people and the conversation He was saying to his companion 'I am going to New York for the purpose of influencing capitalists to invest in my scheme of irrigation" His companion ridiculed the idea He persisted in the declaration of his plan and intentions
>
> Three weeks later, early one morning, she dreamed she saw this man coming up the street in New York leading to her house, and saw her father go forward to meet him She immediately awoke with the impression strongly upon her, went to the window, threw open the blinds and there was this man coming up the street, having just left the train from the West and her father was going forward to meet him He came into the house She related to him her vision, to the most minute particulars of time and circumstances—some of which were not agreeable for him to hear He was thunderstruck—declared she must have been present, as no one not actually present could have given the particulars which she described—and he advised her, as she expressed it, to "go into the business"

This person has been known to me for more than fifteen years Her whole life has been one of industry, absolute truth and self sacrifice She is efficient and practical to a remarkable degree, and absolutely free from romance or flightiness

Wundt declares that cases where somnambulists are alleged to have done mental work in their sleep beyond their powers when awake is simply a fiction, and that no such cases have been reported by "competent observers" This woman was a costumer, and has been employed by several leading firms in New York in that capacity She affirms that on several occasions, when planning a costume, she has been utterly unable to carry out her idea in detail and has been obliged reluctantly to abandon it, when at night, in sleep, she has seen the whole idea perfected in every detail, and so vividly that she was able to carry it out with perfect accuracy the following day

Instances are numerous where the dream was of some particular event which was really transpiring at the very time of the occurrence of the dream Those most marked and interesting occur during times of excitement and danger, and the dreamers are quite likely to be children, or those to whom the events dreamed of were unfamiliar

Many such cases have occurred in England during her wars with India The following have been thoroughly examined by the Society for Psychical Research The first occurred during the siege of Lucknow

> A girl 13 years old had a brother in the East India Company's service in a regiment of infantry One night she dreamed that she saw her brother riding with other officers at the head of a *mounted* regiment It was not in battle but on a march She saw her brother suddenly fall from his horse, shot down and mortally wounded She described the place, the buildings in sight and the people around him It was all written down at the time by her aunt who had the care of her Five years later the officer who was at his side when he fell, visited the family and, at the request of the aunt, related all the circumstances connected with the brother's death, which corresponded in every particular with the record of the dream
>
> A lady whose husband was engaged at the siege of Moultan, one morning in a condition of reverie between sleeping and waking, saw him fall desperately wounded, she saw the circumstances connected with removing him from the field, which were peculiar on account of delay, and saw him take a ring from his finger and give it to a brother officer, saying ' Take this ring and give it to my wife" The whole scene was in reality being enacted exactly as she saw it, and at that very moment, 200 miles away
>
> Another child 8 or 9 years of age, not asleep but playing with other children in the grounds of the officers' quarters in England, saw her father, who was in India, lying under a tree, bleeding and dying from a wound in his head She described his position, appearance and the location of the wound—was fearfully agitated, and wondered that the other children did not see it Her father was actually at that moment dying in India and under exactly the circumstances which she described

I give these examples of the action of the subliminal self in ordinary sleep, in reverie, and in sudden vision while in the waking state The almost indefinite multiplication of parallel cases which have been abundantly verified would be easy, did time permit They all fall into line with the cases already presented, with the addition of certain perceptive faculties or powers exhibited by the second personality, not possessed by the primary one A hasty survey of these added powers of perception is necessary to our subject

Clairvoyance is still looked upon with suspicion by those who are anxious to maintain a reputation for scientific orthodoxy, and it is so looked upon because there is no method recognized by science for accounting for it The only vision known to science is that obtained by means of the physical eye, all other alleged visual perceptions are set down as illusions and figments of the imagination, and when they correspond to actual events they are explained by pronouncing them "coincidences" Taken as a phenomenon, apart from any theory as to its production, no fact is better established in the minds of those who have had opportunities to observe, than the fact of clairvoyance Those who have never witnessed it have a right to doubt, but the testimony of those who *have*, should be respected It is at least bad taste—it is worse—it is bad *method* to impugn either the honesty or capacity of those who have witnessed a fact, especially when the observers are educated and trained in proper methods of observation

The argument for clairvoyance is threefold There is 1, the anthropologic argument which points out the singular fact that alleged instances of it occur and have occurred among every people of which we have any knowledge, no matter how different in degree of development, environments, climate, comfort, nor how widely separated in locality 2, there is the historical argument which shows that in the literature of every nation which has a literature, from the dawn of letters to the present time, accounts of clairvoyance are found 3 there is the argument from personal evidence, educated clear headed men who have had special opportunities to observe this fact, and whose testimony on any ordinary subject would be received, declare that they have seen instances of it, and hundreds of cases on that sort of evidence are on record Important and full of interest as they are, the anthropologic and historical arguments must be omitted in this hasty examination and only those from personal evidence will be briefly presented

The *Société de Psychologie Physiologique* was organized in Paris in 1885, and was for several years presided over by Charcot Its bulletins were published in the *Revue Philosophique* Dr Dufay, of Blois, during this time presented to this society two separate reports on clairvoyance, which had come under his own observation—one related to his experience with Marie a servant and hypnotic subject of Dr Girault another prominent physician of the same city In one instance when hypnotized, she suddenly stopped in some sprightly conversation in which she was engaged burst into tears and became so weak that she had to be supported, and when asked what troubled her she replied that she saw the son of a near neighbor, and a friend of hers, then serving in the Crimea, and that he was dead—that he had just drawn his last breath When news arrived, it was that this young man had died exactly at the time Marie had seen him On another occasion she read the contents of a letter which Dr Dufay had just received from a military friend in Algiers, and had not yet opened Then at the earnest request of her hypnotizer she went, in her second personality to Algiers, described the correspondent, said he was ill, described his disease and described his surroundings all of which on opening the letter were found to be perfectly correct

Dr Alfred Backman of Kalwar, Sweden, has been fortunate in finding several clairvoyants among his patients Results obtained with two of these are given in the proceedings of the Society for Psychical Research While in the hypnotic state, either one could go far away, wherever directed, and describe scenes and events of which she could have no knowledge—some of which were known to the hypnotizer and some were an entire surprise to him—all of which, however, proved to be perfectly correct

Richet has given many interesting experiments conducted by himself, and Mrs Sidgwick of the Society for Psychical Research, has published a large collection of carefully sifted and verified cases

I have, myself, during the past year found a very excellent subject whom I will call A, whom I first hypnotized on account of illness, but who afterward proved to have psychic perception and clairvoyant powers of a remarkable character Once while in the hypnotic condition, I asked her if she could go away and see what was transpiring in other places, as for instance at her own home She replied that she would try I then told her to go to her home—in a small town 300 miles away and quite unknown to me—and see who was in the house and what they were doing After a minute of perfect silence she said "I am there' "Go in," I said, "and tell me what you find" She said "There is no one at home but my mother She is sitting in the dining room by a window, there is a screen in the window which was not there when I left home My mother is sewing" "What sort of sewing is it?" I asked "It is a waist for D," (her little brother) I wrote down every detail of her description, and then awoke her She had no recollection of anything which had transpired I then showed her the notes I had made of her visit to her home, and desired her to write at once to her mother and ask who was in the house at 4 o clock this same afternoon, where she was, and what she was doing The answer came, describing everything exactly as set down in my notes

On another occasion when I made my visit, it happened to be the day of the races occurring at a well known track some ten miles away, and members of the household where she was residing had gone to witness them Neither she nor I had ever attended these races—we knew nothing of the appearance of the place, of the events that were expected nor even of the ordinary routine of the sport She was put into the deep hypnotic sleep, and thinking it a good opportunity to test her clairvoyance, I requested her to go to the grounds and I carefully directed her on her journey Once within the inclosure she described the bright and cheerful appearance—the pavilion, the judge's stand and the position of persons whom she knew She said there was no race at the time, but that boys were going around among the spectators and getting money, that the people seemed excited, that they stood up and held out money, and beckoned to the boys to come—but she did not know what it meant I suggested that perhaps they were betting. She seemed to look carefully and then said "That is just what they are doing" She then described the race which followed, was much excited, and told who of the persons she knew were winners I then said "You will remember all this and be able to tell M, when she comes home"

It was found that everything had transpired as she had described One of the races had for some cause been a failure, all bets were cancelled and new bets were made, which caused the excitement which she had witnessed She surprised those who were present by the accuracy of her description, both of the place and the events

I once asked her "Who is it that goes away ten, twenty or three hundred miles and sees what is transpiring there—is it A?" "No," she replied laughingly, 'A is here sick in bed, she can't go, it is I who go" "Well, are not you A?" "No.' "But do you not belong to A in some way? Are you A's double?" She replied eagerly "Yes, that is just what it is"

I once asked her how she traveled on these journeys "I go so fast," she said, "and I see everything below me It is perfectly lovely" Once she said "I am passing through a shower, you will have it presently" The sun was shining brightly at the time, five minutes later came a cloud, a dash of rain lasting a minute or two, and then sunshine again

There can hardly be a doubt regarding the fact of supranormal visual perception of some sort in the numerous cases reported by the observers whom I have mentioned There certainly can be no doubt but that the scenes and events minutely and correctly described by some of these persons were entirely beyond the reach of vision by means of the physical organ of sight We must either exclude the facts, or else accept some method of visual perception other than that of normal sight

Some, usually those least acquainted with the subject exclude the facts, some, usually those having a competent knowledge of the facts find it impossible to exclude them Those in the latter class endeavor to explain the facts by various methods Telepathy, a psychic medium, a sixth sense, or some magnetic agency are all invoked for this purpose, but all these theories are themselves hypothetical and unproven, and they are called into existence only for this one special service They are all like the cycles and epicycles of the old astronomy—clumsy and unsatisfactory

To see at a distance of 300 or 3,000 miles, through closed walls or at the bottom of deep rivers requires a *personality*—one with perceptive faculties capable of acting under the given circumstances, and able to report what it sees The primary or ordinary personality is not so endowed—its powers of locomotion and of vision are both limited

The subliminal self can, as we have seen, under circumstances at least, act independently of the physical organs, can traverse great distances in a short space of time, can see under circumstances in which ordinary vision is impossible, and what it sees, it is able to report—or impress upon the perceptive organs of the primary self All this has in many instances been actually observed, in somnambulism, in dreams and in the hypnotic sleep

Accepting this subliminal self with its added perceptive powers, brought into activity, sometimes spontaneously and sometimes by the aid of hypnotism, we are furnished with the key, not only to every form of intelligible automatism—automatic writing, trance speaking, hallucinations of hearing (such as were experienced by Socrates, St Paul and Joan of Arc), phantasms and apparitions—but also to nearly the whole range of accredited phenomena pertaining to spiritualism, without trespassing at all upon the domain of supernaturalism

These, then, are our conclusions

That there *does exist*, probably in each one of us, a *subliminal self* or *second personality*, which is able to act at great distances from the physical body, and which is endowed with perceptive powers far exceeding those of the primary self

That clairvoyance is an attribute of the subliminal self, and in that view is perfectly reasonable, natural, and a proper subject for scientific study

That hypnotism is a means of experimentally bringing this subliminal self into action

It is in no spirit of dogmatism, however, that I bring forward these facts and theories, but sufficient facts have now been accumulated from many trustworthy sources, to make it desirable that intelligent thought should be bestowed upon them, and it is with the hope that greater definiteness may be attained in this work—so important as it seems to me, to men in our profession—that I have ventured to draw your attention to this subject

HYPNOTISM IN THE MANAGEMENT OF INEBRIETY

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md. May 7-10 1895

BY T D CROTHERS M D

SUPERINTENDENT WALNUT LODGE HOSPITAL HARTFORD CONNECTICUT

The impression that the continuous use of alcohol is followed by hyperesthesia and increased sensitiveness and susceptibility to the surroundings is not true, only in exceptional cases All inebriates who use alcohol, opium, or other narcotic drugs, have diminished susceptibility and impaired sensory activities, extending from slight defects to general paralysis, not only of the functional but organic activities, and extending to the entire organism

The inebriate is a neurotic, and irrespective of all first causes suffers from starvation and poisoning The power of control of reason and discernment, is defective, and beyond all outside influences is swayed by the unknown impulses of a degenerate and defective organism The power of a dominant idea lasts only as long as it is not in sharp conflict with the morbid impulses of degenerative process

The neuroses of inebriety is practically paralysis, not of one part of the body, but of the entire organism If the hypnotic state is pathologic, and the three special phases, lethargy, catalepsy and somnambulism, are common symptoms, it is clearly possible that the narcotic effects of these drugs may favor these conditions But in reality the lethargy and catalepsy from poisons introduced from without, and formed within the body, are controlled by conditions that are largely unknown and unforeseen From inference it seems clear that any defect or disease of the nervous system in which the excessive use of drugs is a symptom, follows a different line of degeneration from that called hypnosis In one case, general organic degeneration exists, in the other, the power of control is broken up, and follows suggestions from without Of course no state of poisoning from any of the drugs used in inebriety will permit the power of hypnotic influence to dominate the acts or conduct of the case When the poisonous effects of the drug have passed away, then the unstable nerve centers will respond to external influences in various degrees

If hypnotism is a physiologic state resembling sleep, and not an abnormal condition—only a peculiar susceptibility to certain external influences—it would seem that the inebriate seldom would, if ever, be affected by it The observed facts vary widely, and are not sufficiently clear or well attested to form the basis of any authoritative conclusions The few observers in this special field have not found the same conditions even in the same cases, and at different time widely varying degrees of susceptibility have been noticed On the cessation of the drink paroxysms or when from any cause the person abstains from drink, the reaction is followed by a period of psychical weakness In some cases intense melancholy, or hyperesthetic sensitiveness, and fears of their condition, are fertile fields for hypnotic influence

At this time, there is a degree of prostration and absence of assertive will-power, with strong tendencies to depend on any influences which will afford help Good illustrations are seen in temperance revivals, where at the command of the enthusiastic orator they go forward and sign pledges, make prayers, recite experiences and assert positive changes of life and character These are hypnotic phenomena along coarser lines, and their potency is apparent in the very small number of cases that are permanently benefited In these cases the impression of a dominant idea has become so fixed as to overcome all other tendencies to use spirits again Personal counsel, advice, threats and appeals are followed by the same obliteration of the drink symptom in an equally small number of cases

The inference is that at this period in the progress of inebriety, hypnotism skillfully applied may have a marked value Experience differs widely, and the power of a controlling influence one day is lost the next, and the idea that seems so strongly held at one time disappears later The case which appears to be controlled by the operator, suddenly breaks away and the theories are disproven There seems to be a struggle between the morbid impulses of a degenerating brain and organism, and the power of suggestive thought The latter appears to be both physiologic and pathologic Physiologic when the brain naturally turns for guidance and direction to others, and readily accepts statements of facts which are presented in an emphatic way, and pathologic when suffering from adverse conditions and seeks relief in the promises and suggestion of others The power of hypnotism in the reactionary state of inebriety is apparent in many ways, although not explained or understood, and the permanency of this control is still more obscure The same power in cases who are away from this period, and are termed restored, used to prevent them from taking spirits again, is equally obscure In one instance this power gave the inebriate a special repugnance to drink in a certain old circle of friends, but did not stop him from drinking alone. In another case, he claimed he could not drink in his native city, but drank in a distant town. The power of suggestion that one can not drink again, may hold intact for an unknown period, but its permanency depends on the degree of physical vigor and health, and other influences. This is illustrated in the gold cure specifics. The profound impression made on the organism by narcotic drugs, is strengthened by the hypnotic force of a dominant idea, spirits can not be taken again. This in a certain number of cases is real, as long as the person gives unusual care to his physical condition. If curiosity tempts him to test this statement, the delusion is quickly exposed.

It appears clear that hypnotism is a power in the treatment of inebriety, but its application is limited to cases not under the influence of spirits or drugs. It is not clear that these cases can be so positively controlled, or that command or suggestion will last as long as in other cases. Evidently clearer and more exact studies are necessary on this topic.

Profound hypnosis that is continued from time to time on inebriates varies widely in its action. Some persons assert that its influence is permanent, others say it depends on the presence or proximity of the operator. It is natural to expect that a knowledge of the presence of the operator, and a repetition of the power of control would finally become dominant, to the extent of superseding all other morbid impulses, and in this a cure could be said to follow. It would be a question, whether the susceptibility to hypnotic influence, frequently repeated, is a pathologic condition resembling that which follows the degeneration caused by spirits.

In a case mentioned by Dr. Kerr, in the free intervals from drink in a paroxysmal inebriate, hypnotism was sought and enjoyed. The man was hypnotized often, and the idea that he could not drink, impressed on his mind. He was used to show the power of hypnotism on many public occasions. This was kept up for a long time, until the operator moved away, when the man relapsed. This illustrated the fact observed in other circles, that the frequent hypnotic action will take the place of spirits, and is a condition that is akin to intoxication, and in some cases may be agreeable to the person. I have frequently been conscious of a personal hypnotic influence over certain cases of inebriety which was effectual in restraining them from drink at the time. In all institutions a certain small number of cases never drink in and about the building, irrespective of all conditions. Such cases come and go without restriction, but when away from the institution and its influences, relapse at once. It would appear that both managers and the institutions exercise a hypnotic power which enables the person to keep from drink. The same principle explains the power of faith and prayer asylums, where a dominant idea is urged with great intensity and impulsiveness, and for the time being is made to absorb all other thoughts. In this way the morbid drink impulse is overcome by a class of different ideas, which for the time break up every other thought. This condition has reactions, and the men who are most emotional and absorbed by the suggestions of help and salvation, unbend in private, displaying very opposite traits. This is evidence that the power is hypnotic and depends largely on the operator and the surroundings. It will be accepted as a fact that inebriates are less susceptible to hypnotic influence, and such influence is more transient and uncertain in its duration. Yet this is a power of great therapeutic value in an institution where it can be repeated and made continuous, and where the surroundings are under the control of the operator. To apply it practically it may not be necessary to at once dominate the will of the patient and overwhelm his personality, in abject submission to another's will, only in certain cases. But in all cases the dominance and continuous pressure of suggestion are the essentials. Suggestions that can be carried out and enforced by conditions of surroundings.

By studying these influences on susceptible cases, and forcing their recognition suddenly or slowly, a power of control is built up of practical value. A certain number of inebriates are most clearly held under restraint by the hypnotic influence of certain persons closely associated with them. The death or removal of these persons is followed by a breaking out of the drink impulse.

The special question to be answered is this: have we in hypnotism a therapeutic power of sufficient general application, in the treatment of inebriety and drug narcotics, to demand a technical knowledge of its application and use? It appears that we have. Irrespective of all theories of either the pathologic and physiologic action of this force, its power over the brain centers is assured and demonstrable. As an anesthetic, its application in many cases has attracted great attention, but how far it can be used to control unstable and psychical diseased brain centers is not well understood. It would seem that from the evidence so far, its power in the treatment of inebriety should be utilized in all cases. The operator should first become familiar with the technique, and the general principles of its application, and then put it to practical use and test, the same as any other therapeutic agent.

So far, it would seem the best results may be expected in an institution where the operator can command the surroundings and conditions of the patient. The complexity of all cases of inebriety would most naturally increase the difficulties in the treatment especially in the application of psychic remedies and favorable results are not to be expected in the same proportion or degree as that which follows other means. The fact that a few cases are greatly benefited is the strongest encouragement for its more extended use.

In a summary of what appears to be the sound conclusions of the present knowledge of this agent in inebriety, the following may be stated:

1. The inebriate is a neurotic, and not a good subject when under the influence of spirits and drugs for hypnotism.
2. After the withdrawal of the drugs, a period of marked instability seems most favorable for suggestions. This will be transient unless followed up with persistence.
3. Experience points to the wide extended influence of hypnotism in inebriety, although not known as such, in the psychic forces of public meetings, and the power of dominant ideas impressed with emphasis on the mind.
4. Clinical experience furnishes many facts which seem to prove that in certain cases its value is very marked, also promising from more exact studies greater results.

5 Evidently, hypnotism is yet to be studied and tested by the same methods applied to all therapeutic agents So far, its value in inebriety is established, to what extent and how far it can be used are to be settled by future observers

PSYCHO PHYSICS OF SLEEP—NATURAL AND INDUCED

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY W XAVIER SUDDUTH, M A, M D
CHICAGO

In order that we may more closely follow the line of thought, to succeed let us briefly recite the phenomena of natural sleep

Sleep is preceded by a feeling of drowsiness accompanied by a general feeling of heaviness and intellectual dullness There is also a feeling of weariness of the eyes and a tendency to drooping if not actual dropping of the eyelids The head nods and the individual rouses and yawns and if he is in a sitting posture he seeks a position more comfortable for repose If the person is in a reclining position, various groups of muscles may at this stage of semi-consciousness present the phenomena of spasmodic contraction, the drooping head is raised with a jerk and the contracted limbs are straightened and the whole body assumes a position of complete relaxation

The sensory organs, barring that of touch, are still active,—the sense of hearing being quickened if anything The eyes close and one after another the senses become inactive and the intellectual faculties become clouded The objective mind, no longer in contact with its surroundings, ceases to operate, the subjective mind has full sway and the logical association of ideas comes to an end The sleeper is in dreamland and is no longer astonished at the vagaries of memory or imagination

The number of respirations drops from eighteen to twelve or fourteen per minute, and changes to a costal character, and the quantity of air drawn into the lungs is materially reduced by reason of the diminished action of the diaphragm

The temperature is reduced quite markedly and many persons suffer from coldness of the extremities during sleep, due to lowered heart action

The powers of volition next cease and the sleeper is, to all intents and purposes, for the time being paralyzed There are, however, degrees in the profundity of sleep Only the few are entirely oblivious to their surroundings Most healthy people are what are called, light sleepers,—sleep with one eye open, as it were, and even with the soundest sleeper the duration of profound sleep is brief, not extending over two hours at the farthest

Few persons are capable witnesses upon this subject, simply because it is not their custom to take observations on the phenomena of sleep—they do not lie awake to see

The period of sleep depends upon the individual and his surroundings and needs As we pass through dreamland in going to sleep, so does it form the portal to the waking state Our memory of these hallucinations is vivid or otherwise as we dwell upon them Most healthy persons allow them only a passing thought and pass them by This is an utilitarian age and the dreamer has considerable difficulty in finding an audience "Never tell your dreams until after breakfast" is an old adage that if followed is fatal to dreams, so evanescent are they

A recent writer, Lyman, says "Sleep may be defined, in general terms as that state of the central nervous system in which the higher centers are, to a great extent, in a condition of physiologic quiescence, with all the consequences thereby implied" There has been much discussion as to whether sleep is a cerebral anemia pure and simple, or whether its whole nature is expressed in the term "ganglionic exhaustion" The same author says "there are others, who, while recognizing in experimental results undeniable proofs of the anemic condition of the brain during sleep, still persist in perceiving only one of the collateral and unimportant effects of ganglionic exhaustion To corroborate this most gratuitous assumption of the unimportance of the position which anemia occupies among the causative factors of sleep, they have cited the observation that gourmands frequently sleep after an enormous meal, their red and swollen features meanwhile bearing ample witness to the condition of cerebral hyperemia" The flushed face, however, is no sure criterion of cerebral congestion Dyspneac blood stimulates the vasodilator nerves as well as the vasomotor nerves, and as a consequence the cutaneous system may be flushed while the internal organs are anemic, by reason of the contraction set up by the stimulation of the vasomotor center They forget also that there is a vast difference between a condition of partial stupor engendered by such causes and the physiologic sleep which the laborer enjoys after a day of toil

Webster says "It is a natural and healthy, but temporary and periodical suspension of the function of the organs of sense, as well of those of the voluntary and rational soul, that state of the animal in which the senses are more or less affected by external objects and fancy or fantasy only is active"

Our definition for sleep would be something as follows sleep is a condition of restful repose during which there is complete relaxation of the muscular system with lowered heart action, accompanied by recuperation of vital, nervous and other bodily forces

Lyman also holds that the term sleep, when employed to designate more particularly a condition of rest of the central nervous system is closely allied to that which prevails during activity in certain tissues which are subject to periodical exacerbation and diminution of function, as, for example, the glands The temperature in these structures is found to be much lower during rest than during functional activity It has also been observed that the temperature of muscles is higher during activity than during rest Now, a rise in temperature among other things, means the conveyance of an increased amount of oxygen to the tissues within a given length of time, or, in other words, a condition of physiologic hyperemia "Inversely, rest takes place in the tissues as a consequence of reduced oxygenation and interplasmiatic exhaustion" "That ebb and flow of brain activity (and of the cerebral circulation in consequence) transpire under normal circumstances like other similar manifestations of organic life, in synchronous harmony with the rising and the setting of the sun is proved by the fact that sleep during day time, after a night of activity, is not, and never can be made to be as refreshing as that indulged in after sunset"

Just what influence the diurnal motion of the earth has to do with the interganglionic ebb and flow of the vital forces, I am unprepared at this time to say, but that more credit has been given to this force in the past than should be, seems likely in the light of our present knowledge of physiologic chemistry That sleep is, in a large per cent of cases, the result of "interganglionic exhaustion and cerebral anemia" combined, I am free to admit, but no one who has made much of a study of the phenomena of sleep in the healthy state and especially in children but will admit that there are other elements than those that produce sound refreshing sleep, and *that* in the day time also

Sleep is the natural state of rest for the tired physical or mental organism, but why do infants, animals and men that are not actively engaged sleep? They do not need sleep from the same cause as their more industrious brothers No, another line of causative phenomena must be introduced to account for sleep in a large per cent of cases and that, according to my way of thinking, is found in suggestion

Let us take a familiar example to be found in the habits of the common barnyard fowl They go to roost and rise with the setting and rising of the sun That this is a matter of habit is shown by the fact that they go to roost whenever an eclipse of sun occurs no matter what the time of day There are several ways of explaining this habit In the first place, not having any means of producing light they find their occupation gone with the setting of the sun and they have nothing to do but to retire, then again, their enemies are night prowlers and the fowl find their greatest safety in retirement These experiences have fixed the habit until it has become a second nature with them and all the feathered tribe Pet canaries, however, have to be covered in order to protect them from the light and induce sleep

If the theory of solar control of vital forces were the correct one, why do not all animals sleep at night and not, as is the case with many of them, make that their period of greatest activity? It would appear that the most vigilant and active forms of animal life, in its native state, turn night into day It would therefore seem that habit and necessity are the principal factors in determining the time when nature shall take repose The night prowlers and day sleepers among the brutes seem to flourish in proportion as their nocturnal vigilance is successful, their forced day naps to the contrary notwithstanding

In order to understand how the habit of retiring with the sun or shortly thereafter came to be formed by modern man, it is only necessary to go back in history to more primitive man before he had any means of producing light and credit the same conditions that send the feathered tribe to its roost, to day, with driving him to his cave and to sleep One-half or more of his time was then spent in enforced retirement and sleep, but with the advent of artificial light the wakeful period has been lengthened until now the average city man spends less than one-third and even as little as *one-fourth* of his time in bed and yet seems to get along all right

If he suffers from insomnia it is not from loss of sleep, as is popularly understood by many, but by a disordered nervous system that prevents sleep Who ever heard of a case of insomnia in an otherwise healthy child or adult either, for that matter, that could not be explained on the ground of a disordered mental or physical system?

The idea that brain rest can only be obtained during profound sleep is wholly erroneous It is not essential that a person should lose consciousness in order to rest, and although complete relaxation is essential, it may be obtained in the waking state, and is now taught in all our schools in connection with physical culture exercises

The facts in the case are that most people sleep too much Some of our most noted men have been very light sleepers History tells us that Napoleon needed very little sleep He could catch a ten minute nap in the presence of kings or princes, or in the saddle whenever he needed it and willed so to do The wizard of Menlo Park works days at a time and revives his strength by "cat naps" and says, judging by his own experience "No healthy person requires more than two hours sleep a day, and that there is no excuse for people not utilizing twenty out of twenty-four hours for study or work of some kind" All of which I firmly believe A few minutes sleep at the right time, that is, when one begins to feel weary, is worth hours when one is completely exhausted

The benefit derived is not alone from the sleep, but the relaxation that takes place and the lowering of the frequency of the heart's beats A man's span of life is not measured by the tick of a clock but by the beat of his heart Anything, then, that will keep down the tension of the vascular system to normal, will, everything else being equal, tend to lengthen his days During sleep the rapidity of the heart's action is appreciably modified This is due in some degree to the position assumed There should be a difference of ten beats per minute between an erect and recumbent position in a healthy person and even more in nervous irritable people

In children there is a marked difference between the waking and sleeping state Trousseau examined a number of children and found the waking pulsation 140 sleeping 121, not only this, but the frequency of the respirations is considerably diminished and oxygenation and tissue changes take place less rapidly and consequently nutritive processes are reduced, especially in the brain, unless unconscious cerebration or dreaming is carried on during sleep

It has, for many years, been generally admitted among scientific observers that there is diminished blood supply or a condition of anemia of the brain during sleep It has long been observed that the fontanelles in infants are depressed during sleep but pressed open when wakened Arthur L Durham (1860) demonstrated the marked contrast between the aspect of the brain during functional activity and the repose of sleep

Dr W A Hammond asserted from observations made on dogs and rabbits in 1869 that, "in every instance the pressure was lessened during sleep and increased during wakefulness" It remained for Dr Fleming to demonstrate the practical value of th knowledge of the anemic condition of the brain during sleep by producing sleep on several occasions by compressing the blood supply of the carotids Thes experiments were repeated by Dr J L Corning i 1882 who added the further thought, "that when anemia, within certain limits, is brought about throug the operation of physiologic law or by means of artificial appliances, compression of the carotids, it effects as a concomitant physiologic factor in th production of sleep will be directly in the ratio the interganglionic exhaustion" He based his opinion on the fact that favorable results from compression are more easily produced in the evening than in the morning

It has been cited that the presence of the pneumogastric nerve in the sheath of the carotid militated against the exclusiveness of the theory of cerebral anemia as the cause of sleep I can not see how this in any way interferes, as compression of the nerve would indirectly produce brain anemia by lowering the heart's action and only add to the condition directly produced by compression of the carotids

To the idea presented by Dr Corning, I desire to add the further thought of "suggestion," as an active agent and advocate a *sleep center* governed by the vasomotor center controlling the blood supply of the brain and located in the medulla oblongata at a point extending from the floor of that body to within 4 or 5 mm of the columns scriptorius *Stimulation* of this center causes contraction of all the arteries and consequently rise in blood pressure while inhibition, *paralysis* of this region, causes dilation of the arterial system and marked decrease of blood pressure Fixation of the attention of an individual acquainted with the anatomy of the part upon the multipolar nerve cells, the vasodilator cells, situated in his own medulla oblongata with a view of stimulating their action results in lowering the pulse rate very markedly and if, at the same time, the individual is made aware of the fact that such action will result in producing anemia of the medulla and further reduce the blood supply to the cerebrum and thus produce sleep, he will be affected just in proportion as he has faith in the theory and power of concentration of his mind upon the object desired

It is thus that sleep by auto suggestion is produced But it may be said that sleep so produced is not true sleep but an hypnagogic state We will not quarrel with this statement, but freely accept it and claim there is no difference between hypnosis and true sleep, except in the manner of its induction and perhaps some variation in the order in which the phenomena are produced

In this position we are fully indorsed by Newbold and James In a recent article on the hypnotic state Professor Newbold says "Hypnosis is, in a sense a normal state artificially prolonged" And further it would perhaps be too much to say with Mr Wm James of Harvard, that, "we all pass through the hypnotic state every night while going to sleep Yet the changes which take place in the hypnosis probably do not essentially differ from those of normal sleep"

Accepting the two divisions of sleep, exhaustion and habit, made in this article, we would distinguish between the sleep of fatigue and the hypnotic condition as to the phenomena of invasion, but as for the sleep of childhood and even adult life that comes as the result of habit, and I see no difference in phenomena or subsequent effects, both are normal

Professor Bernheim holds that "there is no fundamental difference between spontaneous and induced sleep" Thomas J Hudson in "The Law of Psychic Phenomena" says "There is nothing to differentiate hypnotic sleep from natural sleep" There are, in fact, many analogies between the phenomena of normal sleep and that of hypnotism" M Liebault (Bernheim's "Suggestive Therapeutics") has very wisely established the fact that "the spontaneous sleeper is in relationship with himself alone, the idea which occupies his mind just before going to sleep, the impressions which the sensitive and sensorial nerves of the periphery continue to transmit to the brain, and the stimuli coming from the viscera, become the point of departure for incoherent images and impressions which constitute dreams "Have," says he, "those who deny, the psychic phenomena of hypnotism, or who only admit them in cases of diseased nervous systems, ever reflected upon what occurs in normal sleep, in which the best balanced mind is carried by the current in which the faculties are disassociated, in which the most singular ideas and fantastic conceptions obtrude? * * * * *"

"In order to fully understand the phenomena of sleep, it is essential to accept the theory of the 'duality of man's mind'" "The broad idea that man is endowed with a dual mental organization is far from being new" "Indeed it may be safely assumed that the conception of this fundamental truth was more or less clearly defined in the minds of all ancient philosophers"

It might not be unprofitable, had we the time, in this connection to inquire as to how far it would be possible by auto suggestion to control our dreams and thus obviate the discomforts incident to unpleasant hallucinations It is sufficient for our present purposes, however, to establish the proposition that the subjective mind is controllable by the power of suggestion during natural sleep and thus show the analogy between spontaneous and induced sleep in this important and particular point

There are many other points of similarity some of which it might be profitable to indicate at this time In the first place, recollection of what has occurred during both spontaneous and induced sleep is in an inverse ratio to the depth of the sleep If the sleep is light, then the subject has a more or less vivid recollection of what has passed when awakened, especially if he is questioned before other impressions take their place But profound sleep is dreamless, at least so far as the memory of the sleeper is concerned, although reasoning from analogy, a condition of absolutely dreamless sleep is very doubtful

I think it is safer to say that the subjective mind is ever active and that the reason we are not, at all times, conscious of its continued activity is because of the preoccupied condition of the objective mind Unconscious cerebration is undoubtedly going on in our brain all the time and it is only when it takes a practical turn that we recognize it

Our dreams are often incoherent and absurd, induced by our semi-conscious condition in which our objective minds obtain through our partially paralyzed senses only imperfect impressions of our surroundings, and even these distorted impressions are subject to modification by our bodily condition at the time

We have incidentally referred to telepathic impressions introduced during natural or induced sleep by means of which any desired mental state may be induced at will—these conditions are held by some to be of a pathologic nature but from long observation I am positively convinced that they are harmless unless carried to the extreme, and, as any good thing may be, abused

Every time a nurse puts a child to sleep by rocking or singing to it, she hypnotizes it and suggests pleasant dreams, and the child thrives upon its treatment Men are only grown up children and are amenable to similar treatment and with like beneficial results when judiciously applied What can be more pleasant to a person who has been suffering from insomnia, with its bad dreams, than to have some one who is versed in the science come in and say "Sleep and dream not," and have faith to believe and sleep peacefully through the entire night? Such is being done constantly in these latter days and we venture to predict that the future has a more rational line of treatment for *disorders of the nervous* system than opiates, in hypnotic suggestion which produces normal sleep when applied with that end in view

We have, in the past, associated experimentation and display with the hypnotic state, but we are now entering upon the era of its application and the first and easiest mode of applying it is in the treatment of sleeplessness

100 State Street

DISCUSSION ON PAPERS READ BY *DRS. HOWARD, MASON, CROTHERS* AND SUDDUTH

DR J H HIBBERD, of Indiana—In my judgment the matter of hypnotism is one of great interest in the present state of evolution in the medical mind, in the large field of neurotic disturbances I think that upon a thorough examination of this question it will turn out to be a greatly misunderstood abnormal manifestation of nervous disturbance I do not suppose that any one in the world can be hypnotized who is not willing to be *I take it for granted that there* must be an abeyance of the exercise of will power when one consents to be hypnotized I agree with Dr Patrick when *he says* that there is no such thing as hypnotism at a distance I do not believe, when a subject comes under the hypnotic influence, that the operator has any other *influence* over him than that of suggestion The hypnotic condition *amounts to an unusual* condition of certain parts of the nervous system, of some of the normal senses, and the subject *goes* off into a condition of catalepsy, trance, and finally somnambulism It seems to me, from investigations that have been made, that this is the natural order in which this condition comes about, but by virtue of frequent use and a thorough knowledge of the process that is going on, the subject arrives at *the* condition of trance and by "cutting across lots" he rapidly comes into the state of simple suggestion A larger proportion of the people of the world and no small segment of the medical profession are accepting the statements of those who make a business of going around asserting that hypnotism is due to some psychic force that comes to the operator *from the subject* This, I believe, never takes place, for it is merely a matter of suggestion The suggestion may come directly *from* the *operator*, it *may* come from the surrounding circumstances, it may come by auto suggestion *There are two* ways of arriving at the truth The better way, the scientific way, is by pursuing an investigation and arriving at facts by actual demonstration Results *obtained in this way are never* absolute but are conditional They are true until other facts are elicited, compared and analyzed and made into a new order of things which is for that time the scientific state Another way, which may be called the philosophic method, is that in which *an* inquirer takes up the results *that* have been obtained by a large number of other *people, compares*, examines *and analyzes* them, and after excluding those facts which have no importance to his subject *and those things* which have been shown to be false, he finds *a* certain number of facts that are of very great importance and then he arrives *at a result* which is sometimes correct but is more frequently incorrect By taking, in *this* philosophic way, the facts as *they* may be found scattered over the world, *and* putting them together, there comes *to me* a conclusion which seems to be worthy of being entertained and accorded further investigation It is this to regard the mind as a compound organ, certain parts of which may be in active *operation* and all the rest remaining in abeyance and producing no results A soldier in battle earnestly engaged in the pursuit of an enemy, may be shot while in that condition and has no knowledge of it until he falls from loss of blood or *from* the wound of some nerve This is simply an instance of the intense activity of one department of his mind which ignores the activity of all other parts of his mind *If we keep this fact in our* minds, *we take* away a large factor in the mystery of hypnotism

DR A E STERNE, of Indianapolis—It seems to me that the condition of hypnosis *does not depend* upon the hypnotizer, but upon the hypnotized altogether I believe that any man can hypnotize if the subject can be hypnotized There is and can be no vital force involved I think that hypnotism is yet in its *infancy* *From* the experience I have had with *this* "power" I believe it to be as much, *if not* more, a power for evil than a power for good I have given up the use of hypnotism as a therapeutic agent and *only use it for* diagnostic purposes, *when I use it at all* I believe that every time a patient is placed under the influence of hypnotism, you weaken *an organism* already weakened In the Charity Hospital in Berlin, we worked for a long time under the instruction of *Professor* Jolly, and it was noticed that in almost the majority of subjects placed under this influence very deleterious conditions arose afterward That the school of Nancy, led by Bernheim, goes *too* far, most physicians, I *think*, are inclined to believe I believe we follow more the school of Charcot, *and* that we should discourage such ideas, although we can not exactly deny them, coming from the source they do If *we do not* discourage the ideas advanced by Bernheim we go into a territory that *is not* distinctly *medical*, we *go into* jurisprudence and the possibilities of excusing from acts of criminality, people who *have* committed *crime in* the hypnotic state I do not believe that a person of good moral principles will do a *crime in* the *state of hypnosis, and* if a person does do a crime under this influence, I believe he is just as much a criminal as if he was not under the influence of the second person This is a question that it behooves the medical *profession to take a stand* upon It is a story of life and death very often, as we have recently seen There is an element of *fraud in* all *hypnotism*, it lies in the person hypnotized I have many a time put a blunt instrument in the *hands of* a good girl and she would make plunge with it if told to do so, but when I put a knife in her hand she would not make use of it when directed to do so

DR G J PRESTON, of Baltimore—*In regard to the question* which the last speaker has touched upon, I think it is one which involves very great issues The *fact that it* has been set up a number of times in murder cases or criminal cases as *an* excuse, makes the *question one* of such importance that we can not disregard it I do not altogether agree with *Dr Sterne, for I believe that a person thoroughly* under the influence of hypnotism will do things which in his normal condition would seem very shameful, not to say criminal We are all familiar with the fact of making our friends undress *themselves*, or eat potatoes, or do a great many *foolish* things under the influence of hypnotic suggestions *How* far that can be carried is a question which is by no means settled I remember seeing a great many such experiments performed in Charcot's clinics seven or eight years ago Dr Stanley Hall, at that time professor of psychology at the Johns Hopkins *University*, was interested in the study of hypnotism, and we worked over some particular phases of it, and among others this matter of criminal suggestion I was not *in a position* to know the subjects very well, but I used to see the experiments done over and over again upon old and upon *fresh* subjects, of giving them a knife, or some harmless powder said to be a deadly poison, and suggesting *their criminal* use *There never* was any hesitation in carrying out the hypnotic suggestion It may be that criminal suggestion is something that has a very *unfortunate* future before it I quite agree with Dr Sterne that we should not regard it *as an* excuse at all, and should educate the popular mind into regarding *it* as no more of an excuse or perhaps not as much *an* excuse as drunkenness I am satisfied that a great amount of hysteria is caused by hypnotism *This is* not so evident in this *country* as it is abroad Any one who will follow the work of some person who has been exploiting hypnotism in one of the larger hospitals abroad will see an enormous crop of hysterics that has sprung up around these unhealthy mental experiments I use *hypnotism* a good deal myself in certain selected cases, I have never had very much success with *inebriety*, although perhaps *some* *I have* had some success with sexual perversion, and have had a good deal of success in treating ordinary hysteria I have never seen any bad results from hypnotism used in a purely therapeutic way The number of persons who can be hypnotized is certainly very limited I should say 10 per cent was a very high average in this country

DR E S PETTYJOHN, of Alma, Mich —I beg leave to disagree with the author's theory to the effect that a man can do as much work on two or three hours' sleep as he can do on the allotted time of eight hours I wish to speak in this connection of two cases that have come under my observation One of them, a school teacher, retires after her year's service to her country home She is very much exhausted, weak and anemic She then sleeps on an average twenty hours out of the twenty-four, taking one or two meals a day This she continues from four to six weeks, after which time she comes out like a butterfly from a cocoon She is then as bright and hearty and strong as if she were a young woman again The other case is that of a school teacher and is quite similar I would like to ask if that is not a recuperation of brain cells by prolonged rest and sleep? The brain cells themselves have not the power of muscular activity and so the process of elimination must come from rest Elimination and repair of the muscular system can be accomplished by the activity of the muscular tissues, but in inactive cells these processes must be secured by rest and how can this better be secured than by the agency of sleep? I would like to see it proved that a man or woman can do as much work on two or three hours' sleep as upon the amount usually taken

Dr B D Evans, of Morris Plains, N J —I think the matter of hypnotism, like a great many departments in the study of medical agencies, is at this time carried to at least an enthusiastic, if not to an unreasonable extent Most persons who claim to be hypnotists or have the power of hypnotizing subjects, are necessarily enthusiasts I have noticed another thing that they have, as a rule, a large number of cases that can not very well be verified by the testimony of any observer I mean by this, that an enthusiastic hypnotist gets results that another person observing does not appreciate, and that if the cases operated upon are taken and studied apart from the person who believes he has operated upon them, that these cases will give a very different testimony to others from that which they give to the person who says that he has hypnotized them The point made by Dr Sterne and Dr Preston, that a very small percentage of persons are subject to hypnotic influences, is borne out by the limited observations I have made along this line The power of suggestion is admitted by all observers I am inclined to think, in regard to the matter of hypnotic suggestion, that the results are obtained principally upon people of a neuropathic organization In all cases that have come under my observation or that I have inquired into I have found that the subjects were people of very limited intelligence or of extremely bad heredity In the animal kingdom this seems to hold good The rabbit, for instance, which is a very stupid creature is said to be readily hypnotized

Dr W S Watson, of Fishkill-on the Hudson N Y —We are hearing a great deal lately, of the evil doings of individuals being ascribed to the influences of other people I believe there must be first a willingness on the part of the subject before it is possible to hypnotize him It is my experience that if my subject is not willing, I am powerless to do anything with him I believe that there can and will be much good come from hypnotism, but I think there should be some very stringent legislation against the public hypnotizing which is practiced in this country

Dr W J Herdman, of Ann Arbor Mich —I can not agree with the statement that hypnosis is not injurious to the subject of it I think there is no question but that it has a deleterious influence I have had two girls under my care who were the subjects of auto-hypnosis They were both sophomores in college One of them had had a severe attack of la grippe As a result of that, she fell into a state of auto hypnosis Her room mate, by "suggestion" probably soon exhibited the same state They were rooming in the house of a lady who had formerly been their teacher but had married a Professor Their condition was discovered by this lady who went into their room and found them both apparently in sleep but while "in sleep" engaged in conversation As they had been children together, while in this condition they talked over the events of their childhood In the case of the first girl this condition lasted only three or four weeks She recovered under treatment for her impaired nervous condition It was three months before the other girl came into a moderately normal condition During this entire period I never made the slightest attempt and did not permit any one else, to throw them into this condition Every time they were found in that state it was by auto-suggestion During the course of treatment of the second case, I asked the lady in charge to bring the young woman to my office She would sometimes drop into the hypnotic state on the street, but usually not until she came into my waiting room which was somewhat warmer than the street I went through every possible test for the condition of the nervous system As the ophthalmologist had his office in the same building, I took her into his dark room and he examined her with the greatest care as to the condition of her eyes During this ophthalmologic examination she was in a state of somnambulism When she was awakened she did not remember that she had ever been in the dark room I had her also in one of my examining-rooms during hypnotism and she could not recall, when awake anything that was in that room Not to make a long story of it, when she fully recovered from this abnormal condition the consciousness of what occurred in that state came back to her and she would recollect the experiences as of a dream She would, while in a hypnotic state at home, recount to those about her, her experiences in my office and in that of the ophthalmologist When she was awakened from that state and questioned about it she knew nothing about those circumstances This young woman is perfectly honest and perfectly straightforward That is her record from early childhood She came into my office once with a friend, after I regarded her as perfectly well She asked me if there was not in one of my inner rooms, a painting I said "yes," and asked if she recollected anything about it She inquired if it was a marine scene I said yes, and asked if she remembered any of the figures in it She asked if there was not a ship in it and a buoy, and this she did as if she were trying to recover a memory of something that had made but a faint impression on her mind She went on recollecting thus one thing after another as if by a great effort of memory In the same way she went through the details of the ophthalmologist's dark room, of which she had no recollection whatever some months before when in her normal condition Now it appears as if she had registered upon her mind in that condition something which was shut out of her mentality when in her normal condition While in the hypnotic condition she would always talk with her room mate about the experiences of her childhood She was then, to all intents and purposes, a child in her manner, speech and allusions On one occasion when she was in the hypnotic state in my examining room, one of her former teachers who had known her very well as a child, was present I asked her questions which she answered in a jerky, petulant way, quite the contrary of her normal manner for when she was herself, she was a perfect lady The Professor exclaimed upon hearing her answer "If that isn't that girl as she was at 9 years of age and exactly as her brother is now, that is a family characteristic" Subsequent experiences and culture had built upon this "family characteristic" and had given her the refinement of manner with which I was familiar, but in the hypnotic state she had gone back to that stage of brain registration which was characteristic of her childhood

What I started out to state was this that the series of experiences undergone by that girl unquestionably weakened her mind Since that time she has been engaged in school teaching Only yesterday I learned that there is something of an arrest or deterioration in her mentality, that she is unable to concentrate her mind as formerly She passes often into a dreamy state and is unable to use her mind as she did three years ago I am satisfied that there is a dissipation of energy in hypnosis, whether it is auto hypnosis or brought about by somebody else's "suggestion" There is a voluntary or involuntary inhibition of the higher centers of brain activity, and by frequent repetition this tends to mental weakness and, as has been stated by Charcot time and again, such persons are likely to become hysterical and purposeless if they were not so previously I regard this study of hypnotism as most valuable to us by reason of its giving to us the knowledge of the physiology of mental action It is no wonder we know so little about its true significance, since physiologists can tell us so little as to how the brain is connected with mental activities Until they can give us more definite information of physiologic psychology we can have still less of pathologic psychology I believe hypnosis to be a mental state closely allied to sleep and also very closely allied to those conditions which we term hysteria

Dr Hugh T Patrick of Chicago—We can not hope to settle the question of hypnotism in this discussion, but it would seem to me desirable to have an expression of opinion in this Section at this time That there is such a thing as hypnotism, I think goes without saying That it may be deleterious, I think goes without saying That its practice should be restricted, I think goes without saying But I would make two pleas, first, that it be accorded a place among our diagnostic and therapeutic aids, a place as limited as you will, personally, I *think it must be* exceedingly limited, but still, a place Second, that it constitutes no short cut to therapeutic success He who would use it must be the well educated, careful, wise physician still

DR W X SUDDUTH, of Minneapolis, Minn —Dr Pettyjohn wanted to know if sleep is not a therapeutic agent If his teacher had broken her hours of work by frequent naps she would not have needed the twenty hours of sleep As to whether hypnotism is an injurious agent or not, depends entirely upon the way it is induced and the individual upon whom the operation is performed I am a living example of nine years use of auto-suggestion In 1882, from nine to ten hours office work and five to six hours microscopic work at night, I broke down with nervous prostration In the summer of 1885, in the old town of Heidelberg, I mastered the matter of auto suggestion by which I could put myself asleep for any time I wished I was so weak that I could not walk more than a quarter of a mile at a time I would go into the forests above Heidelberg, walk as far as I could, and then put myself to sleep for a few minutes at a time Inside of a year's time I had increased my weight to 210 pounds and made a corresponding increase in strength At the present time, I do twelve hours of most intense work daily I breakfast at 7, work from 8 to 12, then have dinner, and take a nap after dinner till 2 o'clock, then I work till 6, get another meal and at 8 o'clock begin my literary work and keep it up till 12 or 1 o clock and then I go to bed and sleep four or five hours I have kept up this routine for nine years, and am in better mental and physical shape than ever before in my life The case of the two girls brought before us by Dr Herdman was not hypnotism at all but simply hysteria The very fact as the Doctor goes on to state, that they have since suffered from mental disease, shows that it was a premonitory sign of mental disease Hysteria can illustrate every stage of hypnosis that you ever heard of

Another point mentioned was that the enthusiasm of the practitioners of hypnotism makes them not good observers I have been in nearly all the laboratories of Europe I have spent fifteen years of solid work on that subject I have not been in practice, I am a student in morbid psychology I have hypnotized at my home on an average twenty five to fifty persons a week They are not hysterical people, but students of the universities I have been connected with The best subjects I have ever had have been those of the greatest vitality the best physique and greatest ability The poorest subjects are those who are weak minded The best results and the quickest results have been with other classes of subjects There are three classes of people who can not be easily hypnotized idiots, because they have no will power, insane people (barring melancholia), and skeptics You can not hypnotize an individual who has no faith in you You can not hypnotize children under 5 years of age I make a distinction between mesmerism and hypnotism and if I had time could prove it to you very plainly Mesmerism appeals to the natural attention, which is common to man and the lower animals Hypnotism appeals to the educated attention I do not use mesmerism I believe that when you set up a machine to mesmerize people and put them to sleep it may be injurious The only results I have ever seen that have been bad were produced in cases where mechanical means were used to mesmerize the subject If you work on hysterical people, you get hysterical results Charcot worked in an hysterical atmosphere In fifteen years of constant use of hypnotism as a means of studying psychology on normal healthy persons, I have never had but one case that showed any hysterical symptoms whatever There are laboratories in Europe which report from six to twelve thousand cases The men I have seen there and the reports which I have received from there, have not shown any deleterious results from hypnosis Where patients were were in the pathologic condition to begin with, you might observe bad symptoms, but such symptoms would have been observed after the administration of ordinary drugs If you put a normal atmosphere about it and use normal methods on healthy individuals, the time will come when hypnotism will be almost a household remedy

DR A E STERNE—I hope the time spoken of by the Doctor will never come I don't want to see hypnosis used in my family We have not to deal with normal conditions as physicians From our standpoint as practical therapeutists I don't want it used

OPERATIVE TREATMENT OF PURULENT DISEASE OF THE ANTRUM OF HIGHMORE, WITH EXHIBITION OF NEW INSTRUMENTS

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7-10 1895

BY WALTER J FREEMAN, M D
Adjunct Professor of Laryngology in the Philadelphia Polyclinic Consulting Laryngologist to the Pennsylvania Institution for the Deaf and Dumb, etc
PHILADELPHIA

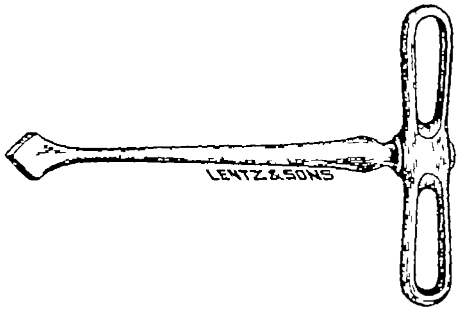
In considering the operative treatment of purulent disease of the antrum of Highmore, I shall speak only of operations for chronic disease Acute purulent cases, which in my experience are of much more frequent occurrence and much oftener of intranasal than of dental origin, seldom require more than the removal of the cause and appropriate local and constitutional remedies

Antrum operations naturally divide themselves into two classes the intranasal and the intra-oral Each has its advantages, and many methods have been devised to meet the indications demanded by the two positions Until recently the general rule has been to open the antrum at its lowest attainable point, in order to secure the best drainage, as with scarcely an exception the importance of drainage was especially urged as the *sine qua non* of correct surgical treatment for it was not deemed inexpedient to have such a pus cavity draining into the mouth, month after month Over one hundred and twenty years ago, however, Hunter, by indicating the middle meatus as a seat for operation, pointed toward other desiderata than drainage While giving due weight to the surgical importance of drainage, we must recognize not only the disagreeable features of pus flowing into the mouth and its injurious effect on the digestion and general health, but also—thanks to Miller—the positive dangers thus engendered, not to mention the great difficulty of healing a cavity so exposed to irritation and re infection from entering food particles and microorganisms

Operators are widely divided as to the best course to pursue in treating this sinus, but most of those who now advocate opening the antrum into the mouth *for the purpose of drainage*, after introducing a drainage tube, *plug it*, to prevent discharge into the mouth or entrance of foreign substances into the cavity Two only, I believe, dissent from this plan Bosworth, who holds that the plug is unnecessary, and Zarniko, who asserts that neither tube nor obturator is required, but that the opening through the alveolus remains closed by a blood clot until this is driven out at the next irrigation

I do not wish for a moment to condemn intra-oral operations, on the contrary, I find them indispensable in certain cases But as presenting fewer objections and offering many advantages not obtaining from this position, I wish to direct more attention to the intranasal methods, and to urge a more careful comparison of the two positions Should we have, for instance, an empyema of the maxillary sinus with a diseased molar or bicuspid as the exciting cause, what more proper than to have the tooth extracted under nitrous oxid gas and a so called drainage tube introduced? The tooth cavity can at this time be reamed out to admit a tube from 4 to 6 mm in diameter and as the tooth *must* be removed it adds but little to the severity of the operation to insert the tube and thus secure, *not drainage, but means freely to irrigate and medicate the cavity* The most desirable apparatus though rather expensive, is a gold tube with a collar fastening it securely to a neighboring tooth, but there is great risk of damage to the sound tooth

Again, let us suppose that after unsuccessful treatment by way of the alveolus or by one of the intranasal forms of operation, we suspect that either a foreign body or a growth is keeping up the irritation It is obviously necessary to make a thorough exploration of the cavity, and now the Dessault-Kuster operation through the canine fossa is the proper one In connection with this, I wish to present a convenient form of drill, which has proved so satisfactory in my hands that I feel justified in bringing it to your notice You will observe that the blade cuts in both directions by a series of half turns, and so penetrates bone very rapidly, and while it cuts a circular hole like a trephine, it is less apt to catch in the soft tissues and lacerate them, as that instrument tends to do in this position The diameter of the perforation, nine sixteenths of an inch, permits the exploration of the cavity with the little finger, or the introduction of an electric lamp or small mirror, or even the overlooking of the sinus by ordinary reflected light After carefully exploring the cavity, removing any cause of irritation, curetting if necessary and breaking down bands, pack lightly with iodoform gauze While Kuster removes the packing in a few days and puts in a drainage tube, Grunwald changes the gauze every three or four days for several weeks before doing so For my own part, I prefer packing daily with thymol iodid gauze for a week and then fitting a large diameter obturator of metal or hard rubber, which is held in position by the pressure of the cheek This allows direct applications to be made to the interior of the antrum, and the progress of the case to be watched



With the exception of the usual and comparatively useless procedure of introducing a small caliber tube through the alveolus, the intra oral operations are best done under a general anesthetic I do not use the phrase, "useless procedure," unadvisedly, I have watched for drainage in such cases, even where the tubes were 2 mm in diameter, and have not seen a trace of pus come down, the cavities at the time being full Again, I have filled the sinus with water and it would not drain, although the ostium maxillare was patulent This can be explained partly by the tubes entering the cavity too far, and partly by the peculiarly thick and tenacious character of the pus It is extremely difficult to judge of the necessary length for these tubes, and it has been suggested to have them fenestrated, but I feel assured that the formation of granulation tissue would offset this advantage It is only when the empyema is getting well, Zarniko's statement to the contrary, notwithstanding, that the discharge becomes milky and flocculent and capable of draining away through a tube of small diameter

We see, then, that the intra oral methods are in many ways not only exceedingly disagreeable to the patient (and not the least of these objections is the necessity for general anesthesia), but even dangerous if the tube is left open, and surgically a failure with reference to drainage if the tube is closed Drainage, moreover, is clearly not the chief consideration, for free drainage is usually secured for many hours at night through the normal openings, by lying on the back or on the sound side, and yet spontaneous cure in these chronic cases is rarely observed Even in the erect posture the tenacious pus once started by the air current, as in sniffing, continues to flow and m empty the cavity Braune has experimentally shown that the air of the antrum can be partially exhausted by forcible inspiration, so that in acute congestions we may even get somewhat of a cupping action by this means

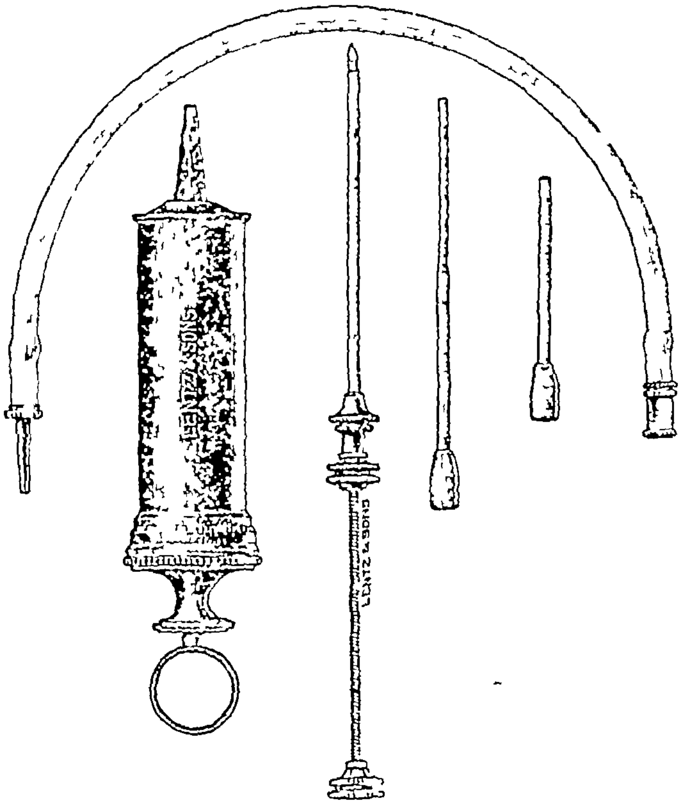
Let us turn now to the consideration of the intranasal methods We will speak of treatment through the middle meatus only to condemn it in unmeasured terms, whether it be through the normal openings, as first suggested by Hunter, or through an artificial puncture, as advised by Hartmann Chiari was able to get pus by way of the ostium maxillare in but one of twenty-eight cases of empyema, and Frankel has been unable to cure a single case by this method. While it is difficult and often impossible for the physician to irrigate the antrum by way of the middle meatus, it is manifestly out of the question for the patient to do so Then, too, the Hartmann puncture can be done only at the risk, as Zuckerkande has shown, of wounding the orbit, or of severe hemorrhage from large blood vessels on the outer wall

Operations through the wall beneath the inferior turbinal, on the other hand, are of real value Mikulicz, in the operation, proposed by him about ten years ago, makes an opening three-eighths of an inch broad by five eighths of an inch long, far up under the inferior turbinal, where the wall is usually quite thin Through this large opening the pus can drain quite freely into the nose, although the perforation is at times some distance above the floor of the antrum It is not, however, an operation to be undertaken lightly, for the pain without total anesthesia is considerable, and the hemorrhage frequently demands tamponing of the naris for twenty-four or forty eight hours This operation, then, is to be ranked with that through the canine fossa for severity, while it is inferior, in that it allows no examination of the interior of the sinus Even with so large an opening, however, some patients, Frankel states, are unable to cleanse the cavity themselves

Less objectionable, though still possessing serious drawbacks, is the Krause method He penetrates the outer wall of the inferior meatus far up and back with a strong curved trocar and canula, washes the cavity once and insufflates iodoform But he puts nothing into the opening to maintain its patulency, and so every second day the canula, armed with an obturator must again be forced into the cavity If one considers how rapid the healing of such punctures is, and the great tendency there is for granulations to form, he will realize that the treatment con stitutes really a series of operations which must be done under cocain Bloch objects to this method, on the ground that the opening is extremely difficult to find While some of Krause's cases are cured in a few weeks, others continue treatment for months, and few could be found in this country to submit to such an ordeal Another objection to this method is that the patients are unable to carry out the treatment themselves Again, both Krause's and Mikulicz instruments are too large to be used in making a trial puncture, so that the diagnosis in obscure cases must be confirmed by another method before undertaking theirs

While many ingenious methods have been devised for the intranasal operations, one very important thing seems to have been overlooked, viz, a simple and practical means of keeping open the perforation, so that the treatment may be readily carried out by the patient as well as the physician To overcome this objection has been my principal aim in the operation which I now present In suspected cases of empyema it is often necessary to irrigate the cavity, as first proposed by Ziem, to determine whether pus be present While he prefers to make the puncture through the alveolus, the majority of operators lean to the intranasal position Lichtwitz goes so far as to make a trial puncture under the inferior turbinal, and finding pus, operates upon the sinus through the mouth Following him, I also use a straight trocar and canula, but instead of making the opening as he does in the Mikulicz Krause position, I perforate low down and more anteriorly The nasal duct lies from 30 to 35 mm from the naso-labial junction, and unless it opens in a furrow, its exit is high up under the turbinal As I keep close to the floor of the nasal fossa, I may at times have to penetrate thicker bone, but this is quickly and almost painlessly done, and the disadvantage is compensated for by entering the cavity near its bottom and thus securing better drainage, while the risk of injury to the tear duct is avoided and a resting place for the head of the tube is obtained inside the pyriform aperture The inferior turbinal and naso antral wall beneath it are first anesthetized with 10 per cent cocain solution, using this trocar and canula, a few taps with the mallet causes it to penetrate the wall the entrance into the antrum being unmistakably recognized by the absence of further resistance Withdrawing the trocar, warm sterilized normal salt solution is at first gently, later with considerable force, syringed through the cavity Should the water return perfectly clear, even after repeated flushing, remove the canula and no harm results' I would emphasize *repeated* flushing, for in one case I used over a pint of water before obtaining a trace of pus, but finally washed out a pus cast of the cavity, the presence of which had caused a marked edema of the eyelids on that side When pus is present, however, I do not remove it at once, but reintroduce the trocar, remove the two nuts and holding the trocar accurately in place, the hand resting against the patient's face, withdraw the canula It is to render this possible that the trocar is twice the length of the canula I now slip a drainage tube over the trocar till it penetrates the cavity and withdrawing the latter, complete the washing of the sinus by syringing through the long silver tube in the set (the wash tube), which accurately fits the permanent air is blown through to dry it, and then an antiseptic powder is insufflated The operation, including cocainization, and treatment, takes but eight minutes, and few complain of any pain The physician should treat the case for the first few days until the nose becomes accustomed to the tube, later, the patient can learn in a minute to pass the wash tube and cleanse the cavity for himself

Before undertaking any operation on the antrum, its position should be determined by grasping the three points forming, as I call it, the antral triangle—the thumb in the canine fossa, the first finger on the malar process and the second finger on the edge of the orbit Within these boundaries must lie the antrum, and knowing this, one can hardly go astray The set of instruments necessary for this operation consists of a trocar and canula, silver drainage tube and a mallet, for irrigating the cavity, a wash tube, syringe and rubber tube with connections The drainage tube may readily be cut down to fit the case The trocar is 16 mm long and 3 mm in diameter



The canula is steel, as softer metal splits in penetrating thick bone The wash tube goes nearly through the drainage tube in order to free it of any accumulations

Among the many advantages of this operation are 1, the ready acquiescence of the patient, 2, the celerity and slight degree of pain with which it is done, 3, the completion in one short séance of the diagnosis by lavage, and the operation for therapeutic purposes, 4, the small wound and the loss of only a few drops of blood, 5, the ease with which patients are able to treat the cavity themselves, and 6, the fact that total anesthesia, and therefore assistants, are unnecessary

The disadvantage is that the cure is delayed beyond that reported for some of the other antral operations, but when once healed, these cases do not seem to have the reported tendency to recur With the enlargement by one-third, of the caliber of the over those I used four years ago, the cases have method of treatment the outlook is most promising The cases which have resisted treatment, and which have shown no progressive tendency to improvement under irrigation, have usually revealed some cause for the continuance of suppuration on exploring through the canine fossa The ease with which remedies may be applied to the antrum by this method leads me to hope that others by following this line may suggest more successful remedies Iodoform is out of the question in one's private practice and Chiari denies that it gives the positive results claimed for it by Krause, Siebenmann and others All operators, however, acknowledge the excellent results obtained by packing the cavity with iodoform gauze, and Chiari packs it even through the 4 to 6 mm opening in the alveolus, which he recommends

In closing, a few words of caution suggest themselves Do not attempt to aspirate the cavity The blood vessels are but illy supported and the normal openings being closed, you may cup the cavity as I did with my first case Do not syringe with strong solution of peroxid of hydrogen, as advised in many books Even after the cavity has been irrigated, some pus remains, and the pressure from the liberated oxygen, except with very weak solution, causes intense pain

Do not make an exploratory puncture through the alveolus where dental caries exists, or you may readily infect a healthy antrum

1720 Locust Street

DISCUSSION

Dr Geo C Stout, Philadelphia—We should all feel grateful for any light which may be thrown on the treatment of these obstinate and hitherto refractory cases Dr Freeman's apparatus seems most complete and will add materially to our present technique, which by means of these instruments will be clear cut and esthetic I have now two cases going around with silver tubes in their antra which were introduced through the inferior meatus These cases have not been cured, and the only advantage gained by the wearing of the tubes is a decrease in the disagreeable odor and a lessening of the viscidity of the discharge These tubes have been worn three months and over No favorable results were obtained from the introduction of any medicaments into the antrum, although many were used persistently for some time The pain experienced in introducing the trocar was slight after cocainization excepting on one occasion, when I attempted to introduce it low down near the floor of the nose, and in this case found the wall so thick *and the pain so severe that an attempt to* perforate it higher up was advisable

Dr Holbrook Curtis, New York—I had two questions to ask Dr Freeman before I heard the remarks of Dr Daley, the first was "How many cases of empyema of the antrum are associated with polypoid degeneration of the tissues within the cavity?" The second was 'In how many cases in which he had introduced his tube had he observed an inflammation of the tear duct?"

In my practice I have found the condition of a majority of cases necessitated a free opening either *through* the alveolar cavity or the canine fossa, and packing or curetting I regard the method advanced by Dr Freeman to be of value from a diagnostic standpoint but as a method of cure of empyema of the antrum generally speaking, the method is insufficient and unsurgical

Dr. Casselberry—If one is to open the antrum *in any* case through the nasal wall the instruments and method of Dr Freeman are most perfectly adapted to the purpose It is certainly an improvement on the means employed by Mikulicz or Krause for perforating through the nasal wall, because it provides a canula for continued drainage which can

strated on the patient present is readily accessible to the *patient for self-injection of antiseptic lotions The method of drainage through the nasal wall is best adapted to cases* which are not of dental origin, and in which the teeth are all sound and one wishes to avoid the extraction of any of them It would also serve in any case as an exploratory puncture, to make certain the diagnosis, and as a preliminary treatment *to ascertain if cure will not ensue simply on* the establishment of drainage for a brief period As a rule, however, and always in cases of dental origin, I prefer an opening through the alveolar process, via the socket of the first or second molar tooth A canal about one fourth of an inch in diameter can be made and through it one can curette the antrum to ascertain if there are polypi, granulations or inspissated pus which might delay recovery if undiscovered Then *a gold drainage tube is inserted and worn until* recovery, or for a year or more, when, if a discharge still continues, it becomes a question as to whether a radical operation by a *large opening in the* canine fossa and iodoform packing should be done

Dr B Alex Randall, of Philadelphia, said—I have had little experience personally treating these chronic cases, as I have generally transferred them to laryngologic colleagues but have seen many treated by Dr Freeman's and other methods, and am very favorably impressed with the reasonableness of his procedure We may not be such 'promising medical men" like Dr Beard whom Dr Daly mentions, as to run the same risk of a fatal result, but if my recurring acute antrum trouble ever becomes chronic, I expect to be 'buncoed" at Dr Freeman's hands and *cured* like many of his patients The danger of aspiration of the antrum to which he referred I can substantiate by my personal experience in totally darkening my antrum in a few hours with extravasations through unthinking 'sniffing" in the effort to free the stenosed nares

Dr Freeman (in answer to Dr Stout)—In answer to Dr, Stout, I would ask why he does not operate through the canine fossa and see why the suppuration continues in his cases? When my cases do not progressively improve under the intra nasal method, I seek the causes by exploring through the canine fossa

Dr Klein, who advocates the operation through the alveolus, and the placing of a wire drainage tube, is already answered in my paper The drainage into the mouth is most objectionable

Dr Daley, who is against any but the radical operation through the canine fossa with thorough curetting is answered by the death of the case which he reports in the practice of a New York surgeon, where the antrum was opened through the mouth and septic pneumonia resulted I do not think we are warranted in subjecting our patients *unnecessarily* to this risk Why not continue treating patients by my method, after making an exploratory puncture through the nose? If they do not improve and get well then turn to a more radical method of operating

Dr Curtis asks as to the frequency of polypi of the antrum in chronic empyema I have not found any, and Zuckerkande in his many examinations has found but very few I think many may be deceived by the peculiar swelling to which the mucous membrane lining the antrum is liable on the least irritation It may be so great as even to obliterate the cavity With regard to his other question, whether I had had any case of epiphora, I answer, no, and for the reason stated in my paper, I penetrate below the opening of the tear duct

Dr Casselberry pertinently asks what percentage of cures I have had I have already forestalled this question by speaking in my paper of the possibly slower cure by this method I think if carefully examined, however, my results will compare very favorably with those of others Four of my earlier cases were clinic cases and withdrew from treatment before I had perfected the method Four case I considered total failures and operated on through the canine fossa ten months ago These cases are still discharging, although I carried out fully what Dr Daley advises I only say I wish I had left in the tubes, then at least they were comfortable, now far from it I report six cases of cure among some twenty two antra involved, which sounds like a small percentage These have remained well at least a year Three of the twenty two were done for other physicians and are not under my care Of the four remaining three are —so to speak—recent and are progressively improving

The last case is one of eighteen years standing, now under treatment two and one fourth years As I have cured one

SCROFULOSIS, CHLOROSIS AND TUBERCULOSIS AND THEIR TREATMENT

Read at the meeting of the Mississippi Valley Medical Association, held at Detroit, Mich , Sept 3, 4, 5 and 6, 1895

BY GUSTAV FÜTTERER, M D

PROFESSOR OF PHYSICAL DIAGNOSIS CHICAGO POLICLINIC, CONSULTING PHYSICIAN DEACONESS HOSPITAL ' LIGHT AND HOPE "

I —TUBERCULOSIS AND ITS DIRECT CAUSE

During the present century, medical writers have been very active on the subject of tuberculosis, and we can readily understand this activity when we remember that nearly one-seventh of the human race die of this disease The disease commonly recognized as consumption has been known since the Dark Ages Even Hippocrates has given a good descriptionof it, at least in reference to lung and pleura, finding the characteristics of this morbid process in a suppurative destruction of the affected organ Later on, the above-mentioned suppurative destruction was found in other organs also, but as the changes found in the lungs were predominant, not only in the clinical picture, but also in the anatomic findings, those changes in the other organs were believed to be of a secondary nature, the tuberculosis of the lungs being primary It was observed that the formation of certain nodular bodies preceded the decay or destruction, and each one of these nodes being called a tuberculum, the name of tuberculosis was given to the disease as a whole Certain small dewdrop like nodes were named miliary tubercles by Bayle at the commencement of this century, and Laennec, the celebrated French pathologist, saw the gray miliary tubercle changed to a yellowish color and undergo the so called cheesy degeneration, which he thought to be characteristic of tuberculosis, against which Virchow protested, claiming that other than tubercular inflammatory products could also undergo the process of cheesy degeneration

Tuberculosis has been regarded as an infectious disease for centuries, but the cause and consequently the modes of infection remained a mystery until Klencke and later (1865) Villemin demonstrated this belief to be true, by transferring parts of organs of man and animals afflicted with tuberculosis into the bodies of healthy animals, thus causing general tuberculosis in the animal experimented on Villemin caused general tuberculosis by implanting parts of scrofulous glands under the skin or into the peritoneal cavity of animals, proving that certain forms of scrofula, in fact most of them, are of a tubercular nature Waldenburg, B Frankel, Buhl and others, repeated the experiments of Klencke and Villemin with the same results, and they came to the conclusion that the cheesy material must either be invaded by or give birth to the infectious substance Cohnheim and Klebs believe in a primary invasion of the infectious substance, which then causes all the anatomic changes which tuberculosis brings about, and is at last contained in the cheesy material Charcot and Aufrecht fed animals with parts of tubercular organs, and Tappeiner made them inhale the dust of a dried sputum from consumptives, with the result of producing tuberculosis in the animals

It was now to be expected that the ultimate cause of tuberculosis would sooner or later be discovered, and in the year 1882 Robert Koch published the discovery of the bacillus tuberculosis as the cause of all forms of tuberculosis Koch invented a process of staining the microorganism, which when unstained had hitherto been invisible even with high magnification, and he was thus enabled to demonstrate their presence in all forms of tuberculosis, and their absence in non-tubercular morbid conditions of the animal body He also succeeded in culturing them and again producing tuberculosis by inoculating small parts of such pure cultures into animals This latter experiment closes the chain of proofs of the fact that the bacillus tuberculosis Kochii is the cause, and the only cause of tuberculosis in man and animals For particulars in reference to this discovery and all details, I refer the reader to Koch's *Ætiologie der Tuberculose, Mitheilungen des Kaiserlichen Reichs Gesundheitamtes*, Berlin Bd ii, 1884 Watson Cheyne, Rosenbach, Fluegge and many other competent investigators have repeated Koch's experiments in all their details, and they have all confirmed his results

Now that the tubercle bacillus is thus known and recognized, medical authors have begun the study of its biologic properties, concerning which I will not go into details here It is true that the bacillus tuberculosis retains its infective capacity for one-hundred and eighty six days, even if kept under unfavorable conditions Sputum containing tubercle bacilli was dried and kept for this length of time, and animals were then infected by it When we consider this, we will understand how very much we are exposed to infection The bacillus tuberculosis is 1 5 to 3 5 μ long, slender in comparison with its length, and slightly bent When Koch published his work, he had found the bacillus under the following conditions in 19 cases of miliary tuberculosis, in 29 cases of tuberculosis of the lung (here especially in the sputum), in fresh cheesy infiltrations and in cavities, the walls of which were breaking down , in tubercular ulcers of the tongue , in tuberculosis of the pelvis of the kidney, the uterus, the testicle ; in 21 cases of scrofulous glands , in 13 cases of tuberculosis of the joints , in 10 cases of tubercular affections of the bones , in 4 cases of lupus , in 17 cases of tuberculosis of cows , in 273 cases of tuberculosis of guinea pigs , 105 rabbits , 44 field mice , 28 white mice , 19 rats , 13 cats, and in a number of tubercular dogs *hamsters*, pigeons, chickens and other animals

The existence of the tubercle bacillus being now established, we must next ask, What are its modes of life? Where do we find it outside of the animal body, and how does it reach human beings?

II —MODES OF INFECTION

I will select a few typical cases to demonstrate the different modes of infection

Case 1 —*Tuberculosis by Inhalation* Two girls, say from 15 to 30 years of age, enter a room in which a consumptive is staying One of these girls belongs to a family in which consumption is hereditary Her father, or mother, or grandfather, or grandmother died of tuberculosis She is pale, tall and slender , her chest is flat, and her ribs are not very elastic, but rather rigid, as shown by her shallow breathing , she has a little cough due to a bronchitis which comes and goes The other girl is of a healthy appearance, and consumption can not be traced in her family The patient coughs and expectorates into a cuspidor, the upper margins of which are slightly soiled with the sputum , some of the sputum even falls on the floor or carpet, from which after becoming perfectly dry, it is stirred into the air by an air current and is inhaled by both visitors The dust containing the tubercular poison is drawn into the larynges and into the bronchial tubes of both individuals The healthy girl with great excursions of the walls of the chest and a strong expectorant power will soon, that is to say, in the *course of a few hours, expectorate the foreign substances*, while they will remain in the air passages of the other girl They now mix with the bronchial exudate, and as the tubercular organisms find in this conditions suitable for life—moisture, temperature, and nutritive material—they grow and multiply In number they multiply to thousands and are constantly moved up and down with the mucus in the bronchial tubes Though some of the mucus and some of the bacilli are expectorated, thousands remain and continue to multiply The upward and downward movements of the mucous column, laden with bacilli, cause friction against the bronchial mucous membrane, producing defects of the protecting epithelial layer, especially at points in the smaller portions of the bronchial tree, where its branches bifurcate at more or less right angles (Rindfleisch) This unprotected portion will be the point of entrance for some bacilli, they are rubbed into the deeper tissues of the bronchial mucous membrane, and once seated there, they bring about the formative action on the surrounding cells natural to them (Baumgarten), leading to a multiplication of those cells, which finds its visible expression in the grayish, dewdrop-like *miliary tubercle* (Bayle) or in a more diffuse production of cells, *the tubercular granulation* , or in a filling out of air cells with this newly formed cellular material,—*cheesy pneumonia* Whether the product be a miliary tubercle, or a tubercular granulation or pneumonia, they all have this in common , they all contain numerous tubercle bacilli as long as they are fresh , they soon show a lack of nutrition , they soon show a dying of the cells, a necrosis which presents the appearance of dry Swiss cheese, therefore called cheesy degeneration, and at this stage they show no more, or but very few, tubercle bacilli These cheesy, degenerated portions gradually take up serum again, becoming moist and soft This soft cheesy substance, representing a decayed part of the affected lung, again shows incalculable numbers of tubercle bacilli It is partly expectorated, thus furnishing the source of numerous infections in the outer world, and leaving a cavity behind These cavities may be the size of a pin's head or may occupy a whole lung I said before, a part of the cheesy material is expectorated , another part gets into the adjoining branches of the bronchial tree and causes the same changes mentioned above , while some may reach the principal bronchus of the other lung which is thus far not diseased, and infect this also Again, another part may reach the larynx, the epiglottis, etc , and cause a tubercular laryngitis , while again other portions may reach the mouth, but instead of being expectorated, be swallowed, thus causing an intestinal tuberculosis The lips of such patients will naturally very often be covered with many tubercle bacilli and if they kiss any one the tuberculosis may thus be transferred One of the localizations in the lung may break into a vein, causing a dissemination of the tubercular virus throughout the whole body, thus producing a general miliary tuberculosis

The case above described would represent a typical case of tuberculosis caused by inhalation It is understood that the anatomic changes of the lungs, the bronchial tree and the larynx are accompanied by the common clinical symptoms , fever, emaciation, shortness of breath, cough, pleuritic pains, etc Instead of a female, a male might be infected , instead *of the stated age, the patient might be at any age*, although those between 15 and 30 *years are most* frequently affected The descendant of a healthy family, too, may become infected but this is exceptional

Case 2 —*Food tuberculosis caused by swallowing tubercle bacilli* The drinking of milk from a tubercular cow and the eating of diseased parts of meat not infrequently cause intestinal tuberculosis I have made the post-mortems of quite a number of cases of purely intestinal tuberculosis, milk having been regarded as the carrier of infection Tuberculosis of the intestinal tract may also result from the virus being transferred in kissing If we shake hands with a consumptive who has just wiped his mouth with his hands, or handled his handkerchief, our hands may be covered with tubercle bacilli which may easily enter our mouths and produce the same effects as above described It is true that in many cases the acid of the gastric juice may destroy the tubercle bacilli, but the acid is not always present, and so they may pass through the stomach and enter the jejunum and ileum to do harm there

Case 3 —*Tuberculosis by inoculation* A nurse or other person cleans a vessel containing the infected sputum of a consumptive The skin is cracked or a cut is inflicted during the cleaning, and some of the sputum is thus introduced into the blood current General miliary tuberculosis may develop very rapidly I have seen this occur

Case 4 —*Hereditary tuberculosis* This mode of infection has not been cleared up as yet We know that cows give birth to calves afflicted with tuberculosis, while human beings, it seems, are generally not born infected by a perfect tuberculosis, but rather with a predisposition to it This predisposition is generally called scrofulosis, and we will see later that this condition is of the greatest importance, the more so, as it is very much neglected It is also possible but this has not yet been proven, that a direct infection of the fetus by the sperma of the father or the ovum of the mother may take place In such a case, generally local infection and infection of the regional glands exists

III —MEASURES INTENDED TO ARREST THE SPREAD OF TUBERCULOSIS WHAT MEASURES ARE NECESSARY?

1 Early diagnosis of the disease by a physician There should be medical centers in all parts of cities where poor people who are suspected of having tuberculosis may be examined free of charge, and in case the examination should reveal tuberculosis, their relatives should be informed of the nature of the disease, and printed directions given them, enumerating the precautions which are necessary to prevent the disease from spreading The people in general should be advised to consult a physician as early as possible when tuberculosis threatens Early diagnosis is very important, as cases in the first stages give the most recoveries, and the sooner a case of tuberculosis is discovered, the sooner protective measures can be introduced

2 Disinfectants should be given to the needy, free of charge, covered porcelain vessels as sputum receptacles, and covered vessels into which the handkerchiefs, underwear, bed clothes, etc, may be deposited and boiled, should be furnished at the lowest possible cost

3 The patient should be instructed to deposit his expectorations very carefully in the above-mentioned covered porcelain vessels, which should contain some 2 per cent solution of carbolic acid or only water All cuspidors in the rooms occupied by the patient should contain a disinfectant or water, preventing the drying of the infectious material

4 The handkerchiefs of the patient should be well cared for Not less than two should be used daily, and when a new one is taken the one used should at once be put into a covered vessel and boiling water should be poured on it Every night all the wash collected should be boiled for half an hour

5 The body and bed wash of the patient should not come in contact with that of other members of the family until after it has been boiled or better yet, not at all

6 The patient should sponge his whole body at least twice a week, and should direct especial care to the cleaning of his face and hands He should also keep his finger nails cut very short and well cleaned, as the spaces under the nails are gathering places for tubercle bacilli

7 The patient should not kiss anybody

8 Teeth and mouth should be kept clean

9 The patient should sleep alone in a room This room should be well-aired all day It should have no carpet, and the floor should be washed every day

19 The patient should not attend large gatherings except in the open air He should not visit theaters, concerts or restaurants

11 The patient should be very careful not to expectorate on the street, on the floor of street-cars, etc

12 The patient should not shake hands with other people

13 In all places where drinks of any kind are sold, glasses should be cleaned in running water, and should not be dipped by the dozen or more into the same contaminated water Dishes, knives, forks, spoons, etc, in hotels and restaurants should be well cleaned

14 Streets should be well cleaned, and on dry days should be well sprinkled

15 The sidewalks should be of stone or cement, and should not be excepted from the cleaning and sprinkling process as most consumptives expectorate on the sidewalks rather than in the middle of the street Dry and windy days give the most chances for infection, and on such days the sprinkling should be very thorough

16 Ladies should not wear trailing dresses, which will come in contact with the ground and thus gather a great amount of infectious material, which, carried home, may become a source of infection to their family

17 All milk consumed in hotels, restaurants and private houses should be boiled Tubercular patients on milk farms and in all places where milk is sold, should not stay in the rooms where the milk is kept, nor should they have anything to do with the milk or its products, as milk is the best medium of infection

18 Hospitals should be erected near or in the cities for the sole accommodation of consumptives, for the following reasons

(*a*) If consumptives are kept in general hospitals, they constantly endanger the other patients, as patients whose constitutions have been weakened by disease or operations are more liable to infection than others

(*b*) In these special hospitals the patients can be taught the necessary degree of cleanliness and the necessary precautions for disinfecting themselves, their sputa, etc, so as to protect others Two weeks in the hospital will generally be sufficient for this

(*c*) Consumptives suffering from intercurrent diseases should be accepted at all times and retained until they have recovered from the attack

(*d*) Patients in the last stages should also be accepted by these hospitals, but should be kept entirely isolated from the others

(*e*) On leaving the hospital, the patients should be induced to promise to keep up the care learned very conscientiously, and if poor, they should be supplied with a quart of milk daily for their own use, free of charge

Gentlemen, this is a long list of rules, and considering the indolence of people in reference to such matters, we can hardly hope that they will all be carried out at any time, although we can promise that "time and money spent in this cause will prove an excellent investment"

We physicians, knowing the biologic properties of the tubercle bacillus, knowing that it can not propagate outside of the animal body on account of its delicate sensitiveness to change of temperature, we know that a perfect disinfection of all products of tuberculosis of man or beast, would in time mean a complete extermination of tuberculosis, and therefore we are not afraid of such a long list of rules as the above Every one of the measures proposed will bring about a certain result, and what one or a few of them alone can do, is shown by Prussian statistics, as published by Prof G Cornet *Berliner Klinische Wochenschrift*, No 20, 1895) The President of Police von Richthofen and the Minister von Gossler of Berlin, after hearing the propositions made in regard to prophylaxis of tuberculosis by a medical board issued orders to carry out those measures in the prisons, penitentiaries, and insane asylums of Prussia with the following result while in the years of 1875 to 1887, 31 persons out of 10,000 died of tuberculosis, beginning from the year of 1887 a gradually decreasing mortality was observed, down to 25 out of 10,000 in the year 1893, which means that from 1887 to 1893, 70,000 persons died of tuberculosis in Prussia, less than was to be expected at the former death rate A similar decrease was observed at Hamburg where physicians headed by Predohl constantly urged the introduction of prophylactic measures, while in Bavaria where those measures were opposed by Bollinger the death rate remained the same until 1892 Although these figures are so very encouraging, one's thoughts must not only wander in this direction We must not forget scrofulosis and chlorosis, possessing as they do the so-called predisposition to tuberculosis, a predisposition which is partly of a mechanical, partly of a histologic, or a chemic nature (diabetes) I have seen so much neglect of scrofulosis and chlorosis and so much misunderstanding, that I would like to call special attention to the principal facts concerning them

IV —SCROFULOSIS

Scrofulosis is generally an hereditary condition, which children inherit from parents who were diseased with tuberculosis, scrofulosis or syphilis Scrofulosis may also be acquired during childhood by living in badly ventilated rooms, to which sunlight, the great oxydizer, disinfectant and purifier, has no access, life in dark and moist basements, over-nutrition, too much bread, potatoes, and other starchy foods, and insufficient cleanliness of the body—all may lead to scrofulosis The skin and the mucous membranes in these cases are in an exceedingly vulnerable condition, and the regional lymphatic glands are unduly affected by any abnormal state of the organs which they drain Once affected, the inflammation of the glands early assumes a chronic character and their products of inflammation have a tendency to undergo cheesy degeneration A superfluous amount of lymphatic vessels and an abnormally rich absorption from all parts of the body is also to be found We are in the habit of differentiating between a torpid scrofulosis and an erethic scrofulosis and this differentiation is not only of theoretical importance Children with the torpid form of scrofulosis have thick lips, the upper one is turned upward, the entrance to the nasal cavities generally show a yellowish secretion of the nasal mucous membrane and the breath has an offensive odor A conjunctivitis gives a red margin to the eye, the cheeks are red, glossy and puffed up, swollen glands of the neck can be felt, or we see scars indicating the seat of past glandular affections

The erethic form of scrofulosis shows us children of a gracile, slender build, a pale almost transparent skin haggard cheeks, small hard glands around the neck and in other portions of the body This form is more easily overlooked than the other These children are considered tender but not sick, and so their parents see no reason for consulting a physician Only too late do they find out their mistake The anemia from which these children suffer (I have already mentioned that they are pale) furnishes a blood for the growing organs which is insufficient in quality and quantity, and this will be the cause for an insufficient development of the different organs, they will remain small and will not be able to functionate nearly as well as other normal organs would But even if, for instance, the liver and kidneys, though small and not of perfect anatomic structure, may functionate quite satisfactorily for many years, certain other organs can not I refer to the heart and the aorta, especially the latter If the aorta is too small—and these patients at the age of about 20 or 25 actually have an aorta the size of a child's—it means that the main channel which conducts the blood supply from the heart to the organs and peripheral portions of the body is insufficient, and there must be and always will be a lack of blood for nutritive and functional purposes in all parts of the body, an irreparable condition which can only lead to the worst results It is now too late! Even transfusion of blood will be of no avail, as there is no room for an additional quantity of blood in these small channels

V —TREATMENT OF SCROFULOSIS

Sunlight, exercise in the open air, well ventilated rooms, if possible on the seacoast or in wooded portions of the country, bodily cleanliness, proper food in measured quantities, codliver oil in winter and iron especially in the erethic forms, are the important factors which bring excellent results We physicians can not cure scrofulosis without the aid of intelligent, conscientious and untiring mothers Children who have not such mothers can only be successfully treated in sanitariums If I am called to a scrofulous child, my recommendations will be as follows

1 Seacoast or country for at least three months a year A shorter stay will not bring any lasting effects (For poor patients sanitariums are to be provided for by municipal and state governments) All the outdoor exercise possible

2 Warm salt water baths lasting for ten minutes morning and night At home these baths may be prepared in the following way

(*a*) Five pounds of seasalt, or if the people are poor, of rocksalt are dissolved in a wooden or porcelain lined bath tub full of warm water

(*b*) This same bath is used altogether six times, but after the first bath a bucketfull of water is taken out each time, and in its place a bucketfull of boiling hot water with one pound of salt is added

(*c*) The bath temperature should be about 98 F Every fourth day a new bath must be prepared

3 During the cool part of the year I would give pure cod liver oil and at other times syrup of iodid of iron

4 If called to either poor, inattentive or negligent people, I would in regard to diet only recommend meat, eggs, milk, some vegetables, but very little potatoes, bread and carbohydrates in general, while in other cases I use the following diet which is employed at the great Hospital at Bercksur-Mer and which has also given me very good results

Breakfast —		
Milk soup	6 times a week,	7 ounces
Milk chocolate	1 time a week,	7 ounces
Dinner —		
Soup	5 times a week	8 ounces
Fat vegetables	2 times a week	8 ounces
Roast meat	6 times a week,	4 ounces
Fried eggs	1 time a week,	1½ eggs
Fresh vegetables	8 times a week	
Dry vegetables	3 times a week	
Prunes	1 time a week	
Afternoon —		
Cheese	2 times a week,	1⅓ ounces
Butter	2 times a week,	⅔ ounces
Sweet pastry	1 time a week,	
Fruit	1 time a week,	2⅔ ounces
Supper —		
Soup	irregular,	8 ounces
Meat (boiled)	4 times a week,	5⅓ ounces
Fish	2 times a week,	5⅓ ounces
Roast meat	1 time a week,	5⅓ ounces
Fresh vegetables	2 times a week,	5⅓ ounces
Potatoes	3 times a week,	5⅓ ounces
Milk and rice	2 times a week,	⅔ ounces

In the torpid forms of scrofulosis the daily amounts of liquid taken should be reduced to two pints, all in all while in the erethic forms the patient should continue to take his usual amount and add from four to six quarts of boiled milk daily, this milk may be diluted with water at equal parts As a matter of course, the frequent catarrhal conditions of the mucous membranes, the affections of the ear, bones and joints, etc , have to be attended to very promptly and perseveringly Concerning the *important treatment* of the small heart and the small aorta, I refer to the treatment of chlorosis in the following chapter

As soon as a lasting rise of temperature sets in, indicating a commencing tuberculosis, I *give my* patients, if they are adults, a No 1 gelatin capsule filled with oil of cloves every two hours, or even every hour from 7 A.M. to 10 P.M.

VI.—CHLOROSIS.

A condition which mainly presents a lessening of the hemoglobin of the blood is called chlorosis. It seems that under conditions so far unknown to us, the iron contained in our food forms a combination with the sulphur compounds in our intestinal channel and thus becomes unabsorbable. The blood becomes pale and watery, the mucous membranes and the skin grow pale and all the well-known symptoms of chlorosis set in. It is hard to understand why people allow the process to advance as far as they do without calling for medical aid, but the fact remains that they see the patient become almost bloodless before they think it their duty to consult a physician. I think if we had an English name for the disease, like the Germans have, "Bleichsucht," that would help matters materially. "Green sickness," I believe is the only term used in this country and I think it to be very proper, but it should be used more, so that more people might become acquainted with it.

VII.—TREATMENT OF CHLOROSIS.

A small heart and a small aorta are often found in chlorotic individuals, especially in cases of chlorosis, complicated with erethic scrofulosis, while in simple chlorosis we oftener find a large heart, and to this I wanted to call your attention particularly for two reasons: 1, small heart and a small aorta give a disposition for tuberculosis and cause constant weakness, constant ailings and early senile changes in all organs; 2, *we can increase the capacity of the heart and the aorta.* Many hundreds of post-mortems on beer drinkers—I mean people who daily drank large quantities of beer, have proved to me that they understand the technique of dilating the aorta and the heart. If they can do this in themselves we can reach the same result in our patients. It is simply the constant increase of pressure in the arterial system caused by the presence of large amounts of liquids consumed that increases the caliber of the aorta and not the alcohol. It is a kind of *internal massage,* and we can do the same with milk, which is harmless and nourishing besides, or with other liquids. Believe me, when I tell you, that with perseverance you will succeed in by far the majority of cases, and you will not only prevent tuberculosis, but your patients will grow much stouter and their ailments which threatened to make life miserable to them will cease.

If we have a case of chlorosis before us, which yields to an energetic iron treatment only in an imperfect or transitory manner, or which shows an imperfect development of the body in comparison to the age, then we may well conclude that the above mentioned condition exists, and act accordingly. It is better to be guided by those marks, than by the percussion figure of the heart, although the latter will often give the clue for our opinion, but only, if we know well the outlines of the normal heart at different ages and if we are well acquainted with linear percussion. There are quite a number of cases of chlorosis with a general obesity and a large heart existing at the same time; in such cases a reduction of liquids rather should precede or go hand in hand with the iron treatment. We must individualize. But I may say that *every case of erethic scrofulosis calls for internal massage of heart and aorta.* This treatment should be introduced in the following way:

I first tell my patients to continue their usual mode of living for two more days, measure *all* the liquids they take and report the whole quantity taken after two days. Half of the quantity used, I consider the average daily amount and then I order one more quart of liquid to be taken each day until the highest limit will have been reached. Different patients range between three and nine quarts daily, while most of them will take from five to six quarts; this means in addition to the quantity they used to take before treatment began. They can take pure boiled milk, or, if this occasions inconvenience, milk and water (boiled) half and half, or the liquid can be made up of beer or any other liquid which they may prefer. Thus we will cause a constant increase of pressure which will gradually but surely—with but few exceptions—cause an increase of weight that in my cases has varied between three and thirty-five pounds within four months, and we will then be able to get a full and lasting result from our iron treatment where we were unable to get it before.

In reference to the medical treatment of chlorosis, I would like to call your attention to the fact, that most practitioners use the iron in too small quantities. I have had a great number of chlorotic patients who had been under treatment with Blaud's pills, three or four a day having been ordered for them with but very little good results. I gave them sixteen three-grain Blaud's pills in the form of Fraser's tablets, four after each meal and four at bed time, ordered them to eat three eggs a day, drink four quarts of milk daily and as much beef juice as possible, and they made a speedy and complete recovery. If I can have it, I give ferratin at meal times beside. After about a week the patients begin to feel life and elasticity returning, and in the course of from six to eight weeks they will have gained considerable color. I advise you to keep those patients under your charge and control until they are perfectly well, as an incomplete recovery will often be followed by bad relapses which can be prevented. The patients are too apt to consider their rosy cheeks a sign of complete health. Only the physician must decide. Has everything been neglected and has an infection with the tubercular virus taken place? Then we are called upon to cure.

VIII.—TREATMENT OF TUBERCULOSIS.

You certainly do not expect me to bring a compilation of everything of value in the treatment of tuberculosis, but I will say that by mentioning no other methods but my own, I do not ignore the others or undervalue them. On the contrary, I believe that different methods lead to good results. Nowadays it almost requires an excuse if we introduce a new remedy for an infectious disease and it is not a serum of some kind, but I shall not offer an excuse as long as mercury cures syphilis. I heartily wish that an antitoxin to the tubercular virus may be found that will reduce the mortality from this disease as the diphtheria antitoxin has done in diphtheria, but while we are waiting for that to come we must not let our patients die, believing that only serum can help. With the different methods employed, so far, and with better hygienic conditions, we already have 24 per cent. of recoveries and we can increase this number, if the people will hear our loud and persistent call "Come early" We know that the curability of tuberculosis has its limits, and that a man whose consumption is by accident cured in the third stage would in most cases be a cripple, that means, he will suffer shortness of breath and chronic bronchitis and never regain perfect health The first and second stages give chances for recovery and after such guarantee comparative health Pleuritic thickenings and adhesions will remain, fibrous changes in the parenchyma of the lungs also, and consequently the dullness which they cause The bronchitis in older cases will also remain, but if there is no temperature for months, if the patient gains flesh and color, if there is no progression of the local changes and if there are no tubercle bacilli, after repeated examination, to be found in the sputum, then we can speak of a recovery just as we do in syphilis

Now, I will make you acquainted with my own method of treatment which, while by no means a panacea, will, I hope, gain your favor in active service if your expectations are reasonable and your endeavors persevering

Basing on Robert Koch's finding (*Mittheilungen aus dem Kaiserlichen Reichsgesundheitsamte Ætiologie der Tuberculose*) that oil of cloves 1 to 300,000 prevents the growth of tubercle bacilli, I have recommended its use for the last eight years, have employed it in my practice for the last five years and a half and have found that this, in reference to tubercle bacilli, a very powerful antiseptic, can be introduced into the human body in quantities which will bring about concentrations of disinfecting strength for a year and a half at a stretch without doing any harm—without, for instance, causing albuminuria I have injected it hypodermically for many weeks at a time and when the injections were made properly, have seen no ill effects I have employed the treatment in 243 cases in the course of five years and a half, and all those in the first stage seem to have permanently recovered I have yet the tubercle bacilli specimen on hand from patients who have not shown any symptoms of tuberculosis for the last three or four years, but who to all appearances are perfectly healthy I have also had some recoveries in the second, and also two in the third stage, but while the second stage sometimes responds well, the time has been comparatively too short for the forming of a far-reaching opinion I have employed this treatment in the following way

1 A No 1 gelatin capsule is filled with the best pure oil of cloves (Merck), and taken with a glass of milk every two hours from 8 A M to 10 P M

2 If the oil of cloves is tolerated, one capsule should be given every hour, if necessary for a year and a half or two years

3 Oil of cloves (Merck) and cold pressed olive oil are mixed in equal parts They are kept standing in a warm place and a hypodermic syringe full is injected into the subcutaneous tissues, first once, then twice a day, but at the same time These injections are continued as long as the patient will stand them for about four weeks Then comes a pause of two weeks, injections for two weeks and so on My patients all have their own syringes with an asbestos packing I first draw the syringe full of absolute alcohol (Squibbs), squirt this on the skin of the back and then inject in two places In one patient I have had an extensive necrosis of the skin following injection, caused by the patient bending over while I was injecting which caused the needle to slip somewhat, and the injection entering the layers of the skin I have seen a number of necroses in one other case, but I did not make the injections If you inject into the subcutaneous tissues where the needle is movable, such things will not happen I sometimes make my injections in the supraclavicular regions but here they can not be made very often, and an extensive, but not very marked edema reaching down to the third rib often follows them

I have also used a clove water in cases of exudative pleurisy which I thought to be of tubercular origin In such cases I aspirate with a Dieulafoix, and then wash out the pleural cavity with a three fourths of 1 per cent mixture of oil of cloves and water, which is prepared in the following way water is boiled for two hours, then mixed with three fourths of 1 per cent of oil of cloves, the mixture is filtered at a temperature of 100 F into a bottle which has been thoroughly cleaned and washed with some of the water that has been boiled for two hours The filtrate should be clear at a temperature of 97° F to 100° F Now, for instance, if I should draw out three pints of pus, I would wash out as well as I could with the filtered clove water, and at last infuse two pints (two-thirds of the volume aspirated) and leave them in the pleural cavity, closing up the needle wound I have treated fourteen cases in this way, four children and ten adults The character of the exudate was seropurulent twice, and purulent twelve times In one child, resection of a rib had to follow the washing, and one patient died of tuberculosis of the lungs soon after This last patient left town and the actual success of the washing is not known Twelve patients made rather speedy and perfect recoveries

As the anti bacterial properties of the oil of cloves are so great, and as it can be brought into the system in such large quantities without doing harm, I consider the cloves superior to creasote, but see no reason why it should not be given together with creasote The combined use of both I would strongly recommend

Venetian Building

FURTHER OBSERVATIONS ON SUBMUCOUS INJECTIONS OF CREASOTE IN THE TREATMENT OF LARYNGEAL TUBERCULOSIS

Read in the Section on Laryngology and Otology, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md May 7 10 1895

BY WALTER F CHAPPELL M D, M R C S, Eng
SURGEON TO THE MANHATTAN EYE EAR AND THROAT HOSPITAL, NEW YORK

The employment of remedies by the method of sub mucous injection has been resorted to in but few affections This is probably due to the fact that internal medication and topical applications meet most of the indications for medicinal treatment, The pathology of the initial lesion of tubercular disease in mucous membranes is, however, exceptional Beginning first in the mucosæ, immediately beneath the epithelial layer of cells, the deposits are so effectually protected that, unless ulceration takes place, local applications are of little benefit In these affections it would therefore seem that measures should be employed that would admit of direct contact between the remedy and the diseased tissues

To effect this, either surgical measures or submucous injections must be employed By the latter method, lactic acid, menthol, iodoform and boric acid have been given Some observers have favorably considered lactic acid and menthol, but the other remedies have given only indifferent success Krause says he was led to use lactic acid from its well known property of acting only on diseased tissues and leaving healthy tissue undisturbed He began his injections with a 10 per cent solution of lactic acid, which was gradually increased in strength to 80 per cent There was little pain or reaction until the 50 per cent solution was reached His results from this treatment were fairly good, ,subjective symptoms disappeared, ulcerations healed and infiltrations diminished to a more or less degree Hering, Major, Gleitsmann, McSherry, Rosenberg, and some others have recorded their experience with injections as being on the whole favorable The writer has also employed lactic acid submucously with some success, but all of his injections with this remedy even in 10 per cent solutions caused some pain and soreness, despite the favorable reports of the treatment by submucous injections, some writers assert that they have had nothing but failures from it, so that, on the whole, this form of treatment has not been received with much enthusiasm

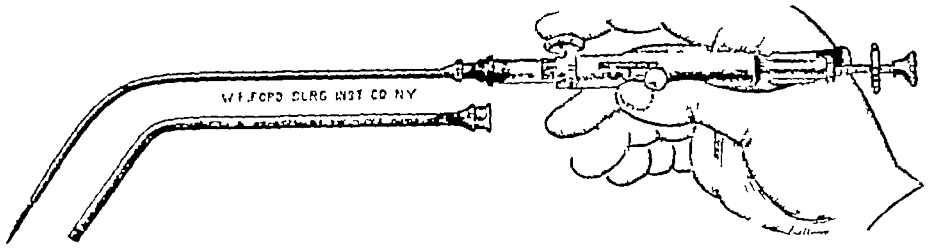
This I think is partly due to the inaccurate and imperfect means which have been used to make the injections The laryngeal syringe of Hering and several others I have seen, consist practically of a long needle with a laryngeal curve, attached to a syringe barrel and piston With this syringe it is impossible to accurately gauge the depth of the injection, and when using a syringe of this kind, I have found it necessary to push the needle deep into the tissues, otherwise the movement of pushing down the piston and the unsteady condition of the surrounding muscular structures were sure to disengage the point of the needle As the tubercular infiltrations are very superficial, it is probable that some of the failures are also the result either of the injections being too deep, or of the fluid welling up around the needle and escaping

The automatic syringe and guarded needle point described in my article on the submucous injections of creasote, in the New York *Medical Journal* March 30, 1895, obviates these difficulties to a great degree. In several instances where there seemed to be no result after an injection, I found that either the needle had slipped or the fluid escaped around it

The point of the needle should always be moderately sharp, and owing to the action of the creosote or lactic acid, the rubber guard should be renewed frequently, otherwise it becomes soft and slips up on the needle when pressure is made The syringe should be held by the operator in as favorable a position as possible, so as to make the injections with ease Separately these directions may appear unimportant, but if faithfully carried out they do much to turn failure into success

Creasote has many qualities which seem to recom mend it for submucous injections It is neutral in reaction, and when applied locally it resembles carbolic acid in causing considerable local anesthesia, it is also antiseptic, sedative and astringent There is much difference of opinion about its effect on the tubercle bacillus According to experiments and observations of some writers there is much evidence to show that creasote has a decided anti-bacillary action The writer inclines to the theory that creasote neutralizes the poisonous products of bacillary origin which are said to produce the fever and digestive troubles of tubercular patients and, that if it does not really kill the bacilli, it practically renders them innocuous, the greatest difficulty being to supply creasote in such a manner and in sufficient quantity to reach all the bacilli

The oily solutions of creasote, in the proportions already published by me, give the highest percentage of favorable results when given by the submucous method, some cases do better when the hydrocarbon oil is left out The omission of the oil renders the solution stronger and of greater consistency Other patients improve more rapidly from the injections of alcoholic solutions of creasote, beginning with a 20 per cent solution and gradually increasing until 50 per cent is reached These solutions cause some burning and irritation In a few instances pure creasote has been employed, but in my experience, it should be reserved for cases where there is considerable and rapidly progressing tissue necrosis In m first injection I rarely used more than one drop o any of the solutions for each injection, subsequen experiments show that two, three or more drops o the oily solutions may be used with advantage ove the arytenoid cartilages and ventricular bands o some patients



The benefits obtained from this method of treatment vary in different patients In some the dysphagia, dysphonia and other subjective symptom have entirely subsided and the disease has seemingl been arrested for several months without much chang in the hypertrophies and infiltrations In other again, the infiltrations have diminished to a poin where further treatment seemed unavailing until change of climate increased the general nutrition an favored further resolution There is still another clas of cases in which the tubercular process may be ar rested in all but one portion of the larynx Thi was well illustrated in one of my patients, who gav a conclusive history of syphilis, and on first examination his laryngeal trouble was thought to be specifi A thorough course of antisyphilitic treatment increased the laryngeal affection Further examination proved the case to be tubercular Under the cre sote treatment the disease was arrested in the cor and in one of the arytenoids The other arytenoi although persistently injected, did not diminish mo than one-third of its former size The mixed trea ment for syphilis was then begun and within a week the delinquent arytenoid was reduced to nearly normal proportions

When tubercular disease infiltrates the perichondrium of the arytenoids, the prognosis is not favorable and it is doubtful if the cartilages ever resume their normal size and appearance under any treatment

Prompt response to treatment can not be expected in a disease so intractable as tubercular laryngitis Many failures to obtain some benefit are, however, in part due to the hopeless spirit with which some physicians undertake its treatment

Physicians who have been more or less successful in the treatment of laryngeal tuberculosis by various methods, will agree that it was obtained only by the systematic and persistent use of the selected methods

While the writer does not wish to be understood to think that creasote is the only drug to be used in tuberculosis of the larynx, he does assert that when the submucous treatment is decided upon, that it should be given by the automatic syringe already mentioned, no matter what remedy is used The exact depth and amount of the injection can then be regulated and the field of injection always kept in view in the laryngeal mirror Usually, the submucous injections have been reserved for infiltrated and hypertrophied tissues and not for the ulcerative stages The ability to give a superficial or deep injection, according to the requirements of the case, has added greatly to the degree of usefulness of the submucous method A resumé of the claims for submucous injections of creasote are

1 In the early stage of the disease when there is only slight thickening of the tissues as a result of the tubercular deposits, the method as described by the writer brings the creasote in direct contact with the deposits Further progress is frequently arrested, and the infiltrations subside

2 When the stage of ulceration is reached, and the ulcers are comparatively deep, with some surrounding infection, injections into the surface of and around the ulcer, assist granulation and arrest further invasion of tissue

3 When the affected tissues are rapidly necrosing, the patient is usually too weak to undergo curetting or excision The injection of creasote is then very beneficial, relieving the pain and laryngeal soreness, hastening the separation of necrosing tissue and arresting the progress of the ulcerations

DISCUSSION

Dr Casselberry—The laryngeal syringe which the author has exhibited is ingenious and seems well adapted to the purpose In delicate intralaryngeal injections it certainly is an object to be able to avoid the slight deviating motion which is imparted to the hand by driving a piston home The spring catch of the syringe might, however, be made to work more smoothly and perfectly

Dr H W Loeb, St Louis, called attention to the possibility of accomplishing good by submucous injection of immunized horse serum Dr Paquin, of St Louis, was quite successful in the use of the serum in pulmonary tuberculosis, and while the speaker had seen a case of laryngeal tuberculosis improve under subcutaneous injections distant from the larynx, he thought that submucous injections would be more successful

Dr Chappell—I regret I can not agree with Dr Gleitsmann when he says it is an easy matter to regulate the depth of a submucous injection in the larynx with an ordinary laryngeal syringe and needle I realize the success of submucous injections depends in having a guarded needle The spiral spring in the barrel of the syringe has to be very strong

A COMBINED UTERINE IRRIGATOR AND DRAINAGE TUBE, WITH INDICATIONS FOR ITS USE

Read before the Loup Valley District Medical Society at St Paul Neb, March 12, 1895

BY O GROTHAN, M D

ST PAUL, NEB

The need of uterine drainage as based upon modern surgical principles is or ought to be so well understood that anything said in this direction may seem as though treading on already well beaten grounds Yet the importance of the subject will bear repeating, even though we have good reason to expect these indications to become fewer and fewer, as time goes on, hand in hand with aseptic obstetrics and gynecology Still there is one thing certain that until we may live in a Utopia of a sterilized medical profession and absolute cleanly patients, the dirty doctor (I mean surgically dirty) and ignorant midwife will always be with us, and leave infection along their wake Beside, an infected womb of ten or fifteen years ago, may at any time, cost our patient the price of her life, irrespective of the law of established tolerance The indication for uterine drainage and irrigation may be considered under the heading of puerperal and non puerperal To the latter a rather wide range of usefulness may be extended, viz

1 After the removal per vaginam of uterine fibroids

2 As Manton[1] has stated after some cases of trachelorrhaphy

3 After the Apostoli treatment

4 According to Murray and Polk, curettement and drainage for pyosalpinx

5 In chronic gonorrheal endometritis, especially where there is narrowing of the cervical canal

6 In subinvolution as the result of septic endometritis and in hemorrhagic and catarrhal endometritis

7 In dysmenorrhea of congestive origin or due to stenosis

8 The septic variety of endometritis accompanied by hypertrophy with excessive glandular secretion, inertia and atony of the uterine muscles, the benefit of drainage and stimulating or antiseptic irrigation is striking The last named condition often calls for curettement, iodoform gauze tamponage and finally the use of proper drainage

9 In sterility, due to stenosis, either congenital or acquired

10 It will answer the purpose of a stem pessary, if such an instrument has ever a legitimate indication

But where the most good may be accomplished is in puerperal sepsis Here the endo-uterine douche alone, as a rule, without free drainage is inadequate Let me state right here that when the lying in patient is infected, nine times out of ten the accoucheur is responsible, but these things may and will occur we all know, and that, from circumstances over which we have no control, as, for instance, where midwives have preceded us, and gross uncleanliness on part of the patient or attendants, both before and after parturition Also from the rekindling of an old infection—the so called auto-infection We should also remember that there are contra-indications for placing a foreign body within the uterine cavity Chief among these are acute inflammations of high grade, whether metritis, endometritis or parametritis, and we must be morally certain that pregnancy does not exist The indications for uterine irrigation and drainage are not difficult to determine, as every text-book and journal treating of the subject recommends irrigation and efficient drainage, so that the question confronting most of us is not *when*, but *how*, to employ this measure, the solution of which is left entirely to our own resources

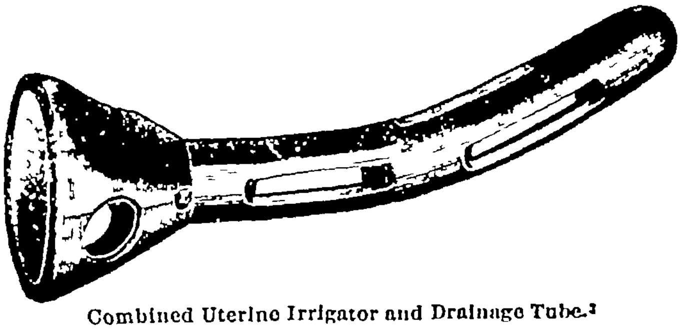
---

[1] Annals of Gynecology, July 1895

Should I now ask you, what are the best means at our disposal for securing uterine drainage, if I mistake not, your answer would unanimously be, iodoform gauze This substance is the material *par excellence* to carry off primary wound secretion, as well as a valuable tissue stimulant and drain in tubercular or other fistulous tracts, and almost an indispensable mechanical hemostatic and uterine stimulant after curettement, but as stated by competent observers, instead of acting as drainage in the uterine cavity, it is simply expelled or acts as an obstructing plug to the discharges

Next Walter S Wells' spiral wire tube, filled with wicking and supposed to establish osmosis between the uterine cavity and a medicated sponge placed in the vagina, has proved to be a failure

Then comes Cherron[2] with 20 to 100 strands of silkworm gut introduced on a special holder, the free ends of the gut being fitted to a celluloid plate This may in a few cases prove of some value as a capillary drain



Combined Uterine Irrigator and Drainage Tube.[3]

We have Bolt's and Wylie's hard rubber drainage tubes, to both of which the same objections are found applicable In gynecology these tubes answer better than in puerperal sepsis, but in either case they fall short of our expectations, first, on account of the grooves being partially closed by the tissues pressing into them, second, and the most serious objection to their use, is occlusion by the vagina falling against the free outlets

In a recent case of puerperal sepsis, where one of these tubes had been placed in the uterus for twenty-four hours, its withdrawal and the simple introduction of an English catheter was followed by the discharge of more than an ounce of exceedingly foul sanguino purulent fluid, Of the two, on account of its freer outlet, Wylie's tube is preferable, but who would think of using a contrivance of this kind for drainage in a surgical wound?

I will here show you a Manton tube which is the best of any on the market, as you will observe it has a truncated extremity and a slot nearly its whole length, but it has the same objectionable outlet as the two last named—hence is of but little practical value

I now present an irrigating drainage tube, constructed of vulcanized rubber or platinum which has, so far as it has been used, proved to answer every indication for which it is intended It is at present the ideal uterine drainage tube because

1 Its outlet can not become *obstructed and overdistend* the flabby uterus

2 It is the only tube through which irrigation may be accomplished and that will admit of continuous uterine siphonage or irrigation in those very virulent cases where life would be extinguished in a day or two

3 *By no other means is it ever safe to irrigate the* uterus without the use of a speculum, as it is never permissible to pass an instrument through the vagina by the sense of touch directly into the uterine cavity, although this folly is sanctioned by high authorities

4 We should never trust even a trained nurse to irrigate the uterus, but after once introducing this tube, a nurse can be instructed to use an antiseptic vaginal douche and then attach a No 7 English catheter—from which an inch or more of the tip has been removed—to a fountain syringe, turn on the stream, and guide the catheter into the tube As the cavity of the tube gradually tapers from the last drainage or return fenestra to the irrigation apertures the catheter will, by introducing it until resistance is felt, *fit snugly and throw the fluid into the uterine* cavity, returning it through the irrigation openings In this way, by placing a patient on a douche pan, intra-uterine irrigation may be resorted to, without the least inconvenience or exhaustion to the patient, as removal of the tube for sterilization, as a rule, oftener than every twenty-four or forty eight hours is *found unnecessary even in case of puerperal sepsis* In non puerperal patients, removal of the tube is not so often indicated Whatever the indication for which the drainage tube is used, the patient must be kept absolutely at rest until its removal

In conclusion, let it be understood that I do not wish to go on record as advocating drainage in every case of endometritis, dysmenorrhea, etc , in fact, its indication is rather the exception than the rule I am aware too, that even the majority of cases of puerperal infection will, sooner or later recover without any local treatment whatsoever, again, a few antiseptic vaginal douches are all-sufficient, or every indication may be fulfilled by one thorough uterine *cleansing But that there are rebellious cases which* tax the physician's skill to the utmost, can not be doubted, and where alertness to the danger signals, and effectual and radical treatment, is the lying-in patient's only safeguard It is equally true that physicians who scout at the idea of all intra-uterine medication and who, in a practice of ten or twenty years, never invade this organ, are far from being alive to their patients' welfare

When any treatment is to be directed to the endometrium two points, however, should under all circumstances, be kept in mind—namely, gentleness in manipulation and conscientious antiseptic precautions

---

TUBERCULOSIS

Read before the Pennsylvania State Medical Society 1895

BY J M BATTEN, M D

PITTSBURG, PA

I wish to show, by clinical observation, that the tubercular *diathesis, predisposition to, or habit, is inherited* to the third and fourth generations, and that consumption has been but very slightly, if at all contagious among those who came under my observation who have not inherited that predisposition to the disease

---

[2] Gazette des Hôpitaux October, 1892

[3] Manufactured by the Aloe & Penfold Company, Omaha, Neb.

Mrs G had five children She and four of the children died of phthisis pulmonalis The remaining child, a female, lived till the age of 84 years and bore ten children, five of whom died of phthisis pulmonalis Three of the latter were married and had children The eldest a male had four children, three of whom died of phthisis pulmonalis—one is still living The second one, a female, married and had one child, and within a year after the birth of the only child the latter died of children s disease and the parents died of phthisis pulmonalis The third female, married and had one child, a male, who is still living The mother died young and the husband died recently of heart disease Two females, unmarried, died young of phthisis pulmonalis Of the five living, the eldest had ten children, two of whom died of typhoid fever The remaining children are living but delicate The mother is 75 years old and has paresis The second, a female, married, had five children all living and healthy The third, a male, in his younger days had hemoptysis but removed from the city to the country and is still living He is married and is the father of five children, all delicate The fourth, a female, married a delicate man who afterward died of phthisis pulmonalis She is the mother of five children, all delicate The fifth, a male, is still living at the age of 58 years He has hemiplegia and is the father of three children small in stature but healthy

One case of another family, Mrs M , who died of tuberculosis had borne four children three of whom died young , two of them of children's diseases, the third at the age of 20 years, of phthisis pulmonalis The mother, Mrs M , died at the age of 40 years Mrs M 's parents were healthy Her mother lived till the age of 86 years, and her father till the age of 74 years The remainder of the latter's children, five in number are all living and healthy with no history of tuberculosis in the family Mrs M is the only case who came under my observation, in which the disease may be said to have been acquired

Of the fourteen cases of widows or widowers who came under my observation, whose husbands or wives died of phthisis pulmonalis, all are now living and healthy

Now the most popular theory as to the cause of phthisis pulmonalis seems to be that the cell must have a deficiency in vital energy and also must have inherited the tubercular diathesis before the tubercle bacillus can attack it with any degree of success Then it follows that a cell may have a deficiency in vital energy, not having inherited the tubercular diathesis, yet the tubercle bacillus may not attack it, or the cell may have a sufficiency of vital energy and an inherited tubercular diathesis and it may be invulnerable against the tubercle bacillus' attacks But I have no doubt, in the case of Mrs M , that the tubercle bacillus successfully attacked the cell with deficient vital energy, without it having had inherited a tubercular diathesis

On the other hand, there are those who may claim the old theory that the disease is transmitted from parent to offspring, and they might ask the following pertinent questions If there was no tubercle bacillus, would there be any tuberculosis, and if there was no inherited tubercular diatheses would there be any consumption? It is a well-known fact that "the tree is known by its fruit" You all remember how Jacob of old, transformed the sheep and cattle into "ring streaked, speckled and spotted," in order to take advantage of his father in law, Laban With our present knowledge of the laws governing procreation we would say that such a change in the color of those animals was caused by the impression made on the parents at the time of copulation That is, the change in the color of the animals depended on the impression on the ova, either through the female or through the fructifying influence of the male—the semen—at the time copulation took place Consequently, there could not have been any other factor to cause the change in the color of the animals When a person of tubercular diathesis is impregnated, or impregnates, there may be claimed to be a constitutional condition in the offspring similar to that of the affected parent This constitutional condition may affect the circulatory, nervous or glandular system in such a way as to interfere with a healthy physiologic action of the same and, thereby, producing a weakness in these various systems, and finally diseased cells and consumption are developed

I believe that the proper plan to prevent this disease, tuberculosis, is to educate young men and young women how they should make their selections, in order that their posterity may not be tainted by disease, and they should also be taught the great importance of making healthy selections

Fifth Avenue and Ross Street

SOCIETY PROCEEDINGS

Chicago Ophthalmological and Otological Society

Regular meeting, held Oct 8, 1895, at 155 Dearborn Street There were seventeen members in attendance, Dr Gradle *in the chair*

Minutes of the last meeting were read and approved

Dr Coleman reported a case of ulcer of the cornea treated by a Saemisch incision and subconjunctival injections of corrosive sublimate De Wecker says in the *Annales de Oculistique* for June, 1895 "I return to large injections of sublimate, 1 to 2000 with eserin I have ordinarily injected half a Pravaz syringe full even in very advanced cases of suppuration with hypopion Only six or eight injections are necessary to obtain recovery, with clearing up of the diseased portion" Abadie, in the *Annales de Oculistique*, 1895, writes "If the patient comes to us with very extensive suppuration of the cornea, and it is not in our power to restore the diseased parts, we are always able to preserve the portion which still remains intact To accomplish this object several methods are at our disposal—the method of Saemisch, the actual cautery What I wish to say is that to day we have a much better method, that is subconjunctival injections of sublimate, and we can in a large number of cases dispense with the actual cautery The following cases prove a surprising success one, a man, aged 48, with an ulcerated point on the cornea and a little pus in the anterior chamber Injection of two drops of sublimate, 1 to 1000 This was repeated on the third day Patient was cured without the slightest alteration in the cornea

Second case, aged 40, with extensive ulcer and large hypopion Had three injections , quite cured in seventeen days

The *Annals of Ophthalmology and Otology*, April, 1895, contains an abstract of Dr Bull's paper on the question of the "Efficacy of Subconjunctival Injections of Mercuric Bichlorid in Ophthalmic Therapeutics" A review of the literature showed great diversity of opinion among the various observers as to the value of this new treatment during the past year Dr Bull had employed these injections in forty-eight cases He summarized as follows 'Pain is always severe in spite of cocain, and reaction is apt to be very severe The only class of cases in which the sublimate injections seem to exert any positive effect in allaying symptoms and shortening the duration were those of scleritis and irido-choroiditis of the non syphilitic type The treatment is still on trial and should not be promiscuously employed in all sorts of cases "

One further quotation after all the laudation of the sublimate injection treatment, and the consensus of opinion in regard to its wonderful effect especially in hypopion ulcer The following review of Dr Bach's work is instructive, although disappointing to our expectations Under the head of "Experimental Researches on Ulcer of the Cornea, Produced by Staphylococci," Dr Bach has endeavored to demonstrate experimentally the efficiency of sublimate injections He inoculated the corneæ of rabbits with staphylococci Both eyes were simultaneously inoculated One was treated simply with instillations of atropin, the other received, in addition, subconjunctival injections, following the technique laid down by Darier In forty experiments the therapeutic results were negative Indeed, the reactionary phenomena were more intense and lasted longer He found that as long as the cornea was not perforated, no microorganisms entered the interior of the eye, even in the hypopion which is the result of exudation of fibrin and leucocytes He tried to find mercury in the eye, but did not succeed He has settled upon the following treatment for corneal ulcers the eye is bandaged, and 6 to 8 drops of atropin are instilled daily, the cul-de sacs are cleansed with physiologic salt solution, and after the ulceration progresses, the borders are lightly touched with the galvano-cautery If there is hypopion, without tendency to absorption, the cornea is punctured to evacuate it The punctures may be repeated

Finally, Dr Coleman's own case G E, aged 22, a machinist, was brought to me on September 30, last Two weeks previous a piece of steel chipped off by a turning lathe had struck the left cornea A fellow workman had attempted to remove the steel and partially succeeded Four days later the steel was removed by the family doctor Hypopion appeared on the day before I saw him At first visit there was deep conjunctival injection of the whole bulb, with a deeply infiltrated, creamy, central opacity of the cornea, two lines in diameter, the surface of which presented a superficial uneven ulceration One quarter of the anterior chamber was occupied by pus, the pupil was semi-dilated and regular under atropin, the iris was discolored, pain quite severe V=fingers at four inches Treatment, September 30 subconjunctival injections near the lower corneal margin of sublimate, 1 to 2000, and sodium chlorid 1 to 1000, 10 minims, atropin 1 per cent and later eserine 25 per cent A hot solution of boric acid was applied to the eye every two hours October 1 there was extensive ecchymosis below the cornea at the site of injection, which prevented the lids from closing The ulcer and the hypopion are about the same Given iodoform ointment in the eye October 2, cornea more infiltrated and the hypopion increased Repeated the injections of 3 minims at three points October 3, infiltration of the cornea increased at the lower three-quarters, and the hypopion was worse Fearing my patient's eye would go on to destruction under the injections, I, for a time, questioned whether to use the galvano cautery or the Saemisch incision As the cautery without perforating the cornea would not empty the chamber of pus and, if used to perforate, might entail a prolapse of the iris and severe reaction, I decided to adopt what seemed to me the most rational procedure, that is, a Saemisch incision, which I did, and pressed out the coagulated pus, prescribed formalin 1 to 1000, to be instilled into the eye every hour October 4, no pus in the chamber, less infiltration of the cornea, and no pain Corneal wound reopened and formalin repeated Since this date the opacity and ulceration of the cornea have gradually lessened, and recovery with slight opacity is assured Given a case of infected ulcer of the cornea, I believe that the galvano cautery or sublimate injections *may be good treatment*, but with pus in the anterior chamber that is not rapidly absorbed, or is increasing under treatment, it seems to me not only rational surgery to give it vent by incision, but very bad surgery to omit to do so

Dr Dodd had used the corrosive sublimate injections in a number of cases, and said his conclusions were very indefinite They proved most satisfactory in cases of severe syphilitic iritis In these cases the results were quite marked In ulcers of the cornea the treatment was of no benefit, and in many cases it made them worse In diseases of the fundus they were of no benefit, the pain of the injection is always severe It is now claimed by recent experimenters that the physiologic salt solution is even better than the corrosive sublimate, because the only action such injections have is to increase the lymph circulation

Dr Montgomery said that many cases of syphilitic iritis yielded rapidly to simple constitutional treatment combined with atropin, and that little dependence could be placed on the results of the few cases treated with corrosive sublimate

Dr Gradle spoke of the cumulative effect of anti syphilitic treatment, and said that but little effect was noticed in such cases at times until the drug had been used for some time, and then suddenly the drug began to act on them It would seem as if the new treatment were doing the work, and that it was simply due to the cumulative effect of the whole treatment He had tried corrosive sublimate injections in only two classes of cases, in one class of interstitial keratitis, and the class of syphilitic retinitis In both of these classes of cases it was possible to foretell the course of the disease, both being slow in development In such cases the injections had proved to be of absolutely no benefit He considered the Saemisch incision the best treatment for ulcers of large size, the cautery the best for the small and deep ulcers

Dr Ware believes in the Saemisch incision when hypopion is present, but he has been able to control most cases by the cautery

Dr Hale spoke of the treatment in Kiel, Germany, and said that the cautery was very much used

Dr Pinckard referred to the large number of cases of ulcus serpens that came to the Massachusetts Charitable Eye and Ear Infirmary from the granite quarries in Quincy The cases are chiefly caused by blows from fairly large stones, the size of a marble, which not only abraded the cornea, but which seemed to paralyze the nutritive function and allow the cornea to rapidly slough In such cases the routine treatment had always been the Saemisch incision, with almost uniformly good results, the cautery being rarely used

Dr Walker, of Denver, referred to similar cases seen there in which miners were struck by small pieces of stone and had noticed the same interference with the nutritive function The Saemisch incision was also chiefly used by him

Dr Coleman said, in closing, that De Wecker, of Paris, recommends the use of eserin instead of atropin in cases of ulcer of the cornea

Dr Pinckard spoke of the use of pilocarpin in a similar way

Dr Colburn showed a piece of iron removed from an eye It entered the eye about four lines from the corneal edge, passed across the globe and lodged in the retina The next day the piece of iron was removed with a magnet The second day a large opacity in the vitreous developed, and on the third day opacity in the posterior capsule began In a few days the whole lens was perfectly opaque although it had not been touched either by the foreign body or by the magnet The wound healed very kindly in a short time, without any pain, redness, or other symptom

Dr Gradle had seen a case where on the fifth day after the injury the whole vitreous was opaque The wound was in the upper cornea and the foreign body (a piece of steel) was easily extracted with a magnet

Dr Colburn said this was the third case he had had in which opacity followed in the lens when the lens was not touched

Dr Dodd had a similar case

Dr Pinckard asked if any member had had a case in which a foreign body was removed from the vitreous and the case recovered useful vision

Dr Montgomery had one case in which a foreign body was removed from the vitreous within half an hour after the injury, and many months afterward the patient had useful vision

A number of cases of foreign bodies remaining in the eye with fairly useful vision were spoken of

Dr Walker reported a case in which a man was shot through the iris and lens, the shot lodging in the sclera behind The shot could not be seen with the ophthalmoscope on account of the hemorrhage, and the eye-ball was removed

Dr Pinckard had seen two cases in which the shot had gone entirely through the eye-ball and lodged in the orbit

Dr Montgomery had seen one such case, but the shot was a large buck-shot, and the eye was so much torn that it was removed

Dr Gradle showed some beautiful photographs of sections of the ear

On motion, the Society adjourned

C P Pinckard, Secretary,

Abstract of the Proceedings of the Eighth Annual Meeting, held in Washington, D C, Nov 12, 13 and 14, 1895

(Concluded from p 911)

FIRST DAY—AFTERNOON SESSION

DR GEORGE H NOBLE, of Atlanta, Ga, read a paper entitled,

ONE HUNDRED AND SIXTY-SIX CASES OF CANCER OF THE PREGNANT UTERUS OCCURRING SINCE 1886

The author's attention was directed to this subject by four cases that came under his observation, his success in dealing with them had encouraged him to look more carefully into the treatment, and as a result he had collected 166 cases of cancer of the pregnant uterus which had occurred since 1886, the time of the Bar thesis Dr Noble then confined himself mainly to the statistics of the treatment and results, referring to Bar, Cohnstein and others for information concerning the age, the period of recurrence, the period of abortions, etc There were twelve partial amputations of the cervix in the seven months of pregnancy, averaging five and a half months, 96 6 per cent of the mothers recovered from the operation, while 8 3 per cent died, 66 6 per cent went to full term, one child dying subsequently, and 41 6 per cent aborted Two mothers had subsequent operations performed for the removal of cancer, but there was recurrence in both cases Another conceived a second time, and died thirteen days after confinement of peritonitis Of the three cases of intra vaginal amputation of the cervix, two recovered from the operation, giving a mortality of 33 3 per cent , the children the same One mother died of peritonitis, one died suddenly six weeks after confinement, and the third had two subsequent operations for the removal of the malignancy The intravaginal amputations give a combined mortality from operations, of mothers 19 3 per cent, of infants 40 per cent Sixteen supravaginal hysterectomies were done prior to the seventh month, with a mortality of 6 2 per cent , six had recurrence of the disease, three had no return and seven were not observed There was therefore an ultimate *mortality* of 66 6 per cent In the sixteen cases in which the records are complete, thirteen cases were lost, a mortality of 82 5 per cent Of the remaining three, one went to full term, and the other two were not mentioned One case aborted thirty five days after conception, aborted again in forty days, conceived a third time, was delivered normally, and was well five years afterward There were twenty-three vaginal hysterectomies In two cases the results were not recorded, leaving twenty one cases, all successful There were seven cases of vaginal hysterectomy in the puerperal period from fourteen to twenty days after abortion or delivery, all recovered

The total number of abdominal hysterectomies was sixteen, twelve of these were Freund's operation, one after Mackenrodt's method, and the remainder not described Of eleven cases, seven died from the operation One case had enchondroma of the pelvis, another had return of the cancer in one year, and a third had a return in a few months, and died seven days after an operation for *ileus due to cancer* of the intestines These three are the only ones with complete records, therefore it is impossible to give an estimate of the ultimate recoveries The products of conception were all lost

Cæsarean section was done forty-three times, as follows conservative (or Sänger) twenty-six, Porro, nine, Freund's, eight times Of the twenty-six conservative operations, sixteen died and seven recovered, in two, the results are not recorded, and one was dead before the operation was performed, mortality in twenty three cases being 43 7 per cent

The number of recoveries in the Cæsarean Porro operations were four, deaths five, mortality of 55 5 per cent In eight Cæsarean sections by the Freund method, there were three recoveries and five deaths, giving a mortality of 62 5 per cent

A short summary shows 1, that vaginal hysterectomy should be safe in the early months of pregnancy and the puerperal state, when there is a reasonable hope for the mother, 2, that abdominal hysterectomy should be done when the uterus is too large to be rapidly and safely removed through the vagina, 3, that at or near the end of pregnancy, Cæsarean section should be resorted to, when the child's interest is to be considered, 4, that Cæsarean section with Freund's operation is permissible when the disease is confined to the uterus and the child is viable, 5, that in doubtful cases, cutting of the cervix and rapid delivery may be judicious when the incision can be made in nonulcerated or non infiltrated tissue, 6, that as there are four chances to one, against the life of the fetus, and as an equal number of mothers may be ultimately cured in the early stages of the disease, the safety of the fetus should not be allowed to hazard the life of the mother, and that, upon the other hand, the futile efforts directed to the interest of the mother when her case is hopeless, should not jeopardize the safety of the fetus in the latter months of pregnancy

DISCUSSION

DR HOWARD A KELLY, of Baltimore, said that cancer of the pregnant uterus is rare He had seen but three cases If the cancer is seen in the early stage when it presents itself as a mere nodule on the cervix, not apparently extending into the broad ligaments and pregnancy is approaching, it would be safe to let pregnancy go on to full term and labor to take place naturally Per contra, if the cancer has advanced to such an extent that there is a possibility of involvement of the broad ligaments, the surgeon could not operate too soon, because under the conditions of pregnancy the growth of cancer of the cervix is much more rapid than it is ordinarily

DR VANDER VEER, of Albany, stated that four years ago he operated on a case, doing a vaginal hysterectomy Pregnancy had advanced about four months He felt happy about the case for two and a half years, at the end of which time cancerous nodules presented themselves at the site of the cicatrix Pregnancy had advanced to full term The patient lived for a period of eight months The pelvis was filled with a cancerous deposit Dr Vander Veer reported another case of cancer of the pregnant uterus, and while the patient recovered from the removal of the uterus, she subsequently died from recurrence of the disease

DR E S LEWIS, of New Orleans, contributed a paper entitled

HYSTERECTOMY FOR FIBROIDS

The author said that hysterectomy for fibroids, now a justifiable and recognized operation for the preservation of health, the prolongation and the saving of life through important operative procedures, minimizing the element of risk, had reached its present enviable position by the substitution of direct ligation of the uterine arteries, for the unsatisfactory methods heretofore employed to secure immunity from hemorrhage, these measures often failing to prevent bleeding and not infrequently there was exposure to infection through the region of the cervix Complete hysterectomy, whether by the vaginal route in fibroids of moderate size, through the abdomen in certain cases, or by the combined abdomino vaginal method in other instances, heralded a brighter era for the future of hysterectomy That exceptions might occur with regard to individual cases, rendering the complete operation inadmissible, he was prepared to admit The author then reported eight cases in which the complete operation was practiced

Case 1 —Patient aged 53 years Tumor the size of a seven months pregnancy Operation performed March 11, 1894 Incision from pubes to two inches above umbilicus Omentum detached from anterior surface of tumor to which it was adherent, a portion of omentum ligatured and cut off on account of free oozing The subperitoneal fibroid attached to the fundus was lifted out and upper portion of ligaments ligated and divided The bladder was then detached and vaginal roof opened in front and behind The lateral vaginal connections and lower portion of broad ligaments were transfixed and ligated with a double ligature and the uterus freed One suture through middle of vaginal vault The incision (abdominal closed) and the vagina loosely packed with iodoform gauze pushed above vaginal roof for drainage on account of some slight venous oozing The tumor weighed twenty-five pounds This patient made a satisfactory recovery

Case 2 —Patient, 48 years of age, had profuse uterine hemorrhages Uterus as large as a five months pregnancy from interstitial fibroid Endometrium curetted and iodine injected without relief Hysterectomy by the vaginal method Recovery

Case 3 —Patient, aged 63 years Diagnosis interstitial fibroid with carcinoma of cervix The uterus reached the middle of the hypogastrium and was about the size of the preceding case Its removal was easily effected in the sam manner Ligaments were secured with clamps The fibroid about the size of an orange, was not weighed Recovery

Case 4 —Patient, aged 44 Uterus enlarged from sma fibroids Vaginal hysterectomy followed by recovery

Systematic delirium Of this type two varieties have been found so far, among the aged delirium of persecution and of grandeur Published cases are rare as yet, but enough are known to show that this delirium is not confined to adults The aged may create delirious conceptions with a cohesion, an energy, a logic—if we may call it so, fully the equal of those found in other periods of life

Moral or instinctive insanity Ritti uses this term to designate those pathologic states consisting principally of an often irresistible ardor for culpable and dangerous acts Age is not exempt from this species of aberration, and the less so, since advancing age with its depressed will power weakens the resistance to morbid impulses Hence, the cases of kleptomania, of homicidal mania, and especially those frequent aberrations of the genital sense observed as often in women as in men

Hysteria is another psychosis which may be found even in advanced age, as Henry has pointed out Anesthesia, and especially hemianesthesia is rare in the aged hysteric, while hyperesthetic zones, and notably the hysterogenous are frequent Convulsive movements of the limbs are also infrequent, but on the contrary, painful and spasmodic phenomena in the viscera are very intense So we may define senile hysteria as a "painful hysteria with splanchnic manifestations " As regards the mental state, this differs but little from that we are accustomed to in younger persons

Somatic symptoms The study of these symptoms in psychoses of the aged is of prime importance All the organs of the economy should be examined with scrupulous care Disturbances of the cerebral circulation (ischemia and hyperemia) are frequent in the aged, either from cardiac lesions or from athero matous arteries The urinary organs rarely escape, micturition becomes difficult, cystitis is frequent The kidneys are often diseased, with concomitant urinary insufficiency and uremic intoxication, and it may even be asked if most of the cases of mental confusion are not due to this intoxication

THE PHYSICIAN IN THE BIBLE AND IN THE TALMUD

Very few people study the Bible as a source of purely historical information The same remarks are also true of the Talmud While not so very few studies have been published of medicine and medical men as represented in these two books, yet it can safely be said that the majority of such studies are practically useless from a strictly scientific standpoint because they are more or less tinged with personal religious sentiments, and lack the purely objective character of historical researches It is consequently very interesting to read a recent historical study of the physician in the Bible and in the Talmud by Dr Preuss,[1] of Berlin, concerning which there can be no doubt but that its representations are entirely uninfluenced by the religious sentiments of the writer

The physician of the Bible and of the Talmud treated not only internal diseases, but also the diseases of the eye, of the teeth and the various surgical affections, especially injuries of various kinds, such as the bites of snakes, fractures and the like In one place it says that when a person tumbles from the roof, then the doctor comes and puts plaster on his head, his hands and his feet Amputations were performed under various indications such as gangrene, in leprosy, and other conditions The Emperor Titus Vespasianus was trephined It is even mentioned that attempts at covering cranial defects were made A very frequent operation was the ritual circumcision The rōphē, as the Biblical physician was called, was also consulted in regard to gynecologic affections, and it seems that he was interested in midwifery

In doubtful religio legal questions the physician, or rōphē, was sometimes called as an expert It is also quite clear that some attempts at scientific investigation were made, because it is stated that students of Ismael examined post-mortem the body of a prostitute, who had been burned to death under the sentence of a Roman judge, in order to determine the number of bones in the human body Like the doctor of antiquity in general, the rōphē was also his own druggist He had a receptacle in which "all remedies are contained " He prepared the theriac, that wonderful mixtum compositum of antiquity which consisted of sixty-four ingredients He spread his own plasters

Concerning specialists we learn only this, that a certain ben Achijah was appointed for "intestinal diseases " of the priests of the temple But in addition to this temple doctor, official medical positions do not seem to have existed Military physicians are not mentioned, and King Joram had to return to his home in order to be cured from sickness This is not so very remarkable, because in Biblical times neither Greece nor Egypt possessed any sanitary systems As regards the time and the course of study of Biblical physicians we possess no information whatever Puschmann[2] assumes that the student received personal instruction from persons experienced and trained in medicine We read of a student of a physician from whom "he had learned all the ordinations of physic " There is no mention of any medical schools

The first physicians spoken of in the Bible were Egyptians, slaves of Joseph Their activity seems to have been confined to the art of embalming The regulations concerning leprosy contain no mention of medical men

[1] Archiv für path Anat u Phys und für kl Medicin, Bd 188, Heft 2

[2] Gesch d medic Unten , B 26

In the Talmud, four men are expressly designated s "the doctor " 1, the physician Thudos or Theodorus who, it is assumed, studied in Alexandria, because he is frequently quoted as saying that in Alexandria every female swine and every cow was castrated before exportation in order to prevent the increase of the race outside of the country It is also stated that he came into the schoolhouse and declared that certain vertebræ and cranial bones placed before him did not come from the same person 2, Tobijah and 3, bar Gionti, concerning whose achievements nothing is known 4, the physician Minjomi or Binjamin, who designates all fluids as noxious for the ear except the juice of the kidneys

The work of physicians was always highly appreciated among the old Jews In Hebrew the designation physician, is derived from a root signifying to relieve, ameliorate, whereas in other languages the term usually comes from a root meaning to know "Even when the physician sees that his patient is near to death he says to him Eat this, not that, drink this, not that, but he does not say, Your end is near" The physician was responsible for his doings Any intentional injury was punishable according to the laws of the land, but if the injury was the result of a mistake on the part of the physician then he was not held responsible to the worldly judge, but the decision and punishment was left to the higher judge It will be remembered that in Greece and Rome the physician was exempt from all punishment, even for the intentional killing of the patient The Jewish physician *was not permitted* to treat heathens any differently from his own fellow-believers, he was to bestow equal care on both This liberal tendency went so far that even heathen physicians of standing were allowed to perform ritual circumcision

Medical services were recognized in those days as vorthy of compensation "A free doctor is no good," aid a wounded man to his assailant, whose duty it vas to "pay the bill," and who wanted to bring the vounded to "a free dispensary " We read of a docor that he had a certain place in his consultation oom where the money he was to have was placed f the doctor observed that a patient was poor, then e gave the patient money and said "Go, strengthen ourself!" Concerning the liberality of the fees of almudic physicians nothing is known

---

HE WORK OF THE OPHTHALMIC SECTION FOR 1895

Preceding issues of the Journal have laid before s readers the work of the Ophthalmic Section hose interested in this subject know best its worth, s scope and its thoroughness Such as were so fornate as to see the members in session at Baltimore re able to add personality to the actual work and ake its value more realistic It suffices to say that every band of ophthalmic workers in the United States and Canada was adequately represented, and that the papers under consideration represent the ophthalmologists of the entire continent

The most casual study shows that the papers and discussions were the result of careful planning by the Section officers To the Chairman, Dr Jackson, and the Secretary, Dr Wurdemann, is due the credit of perfecting as well as devising these plans which were fully adopted by the Section The brevity of the papers and discussions is accounted for, when it is known that each individual was notified in advance of his preparation that but twenty minutes would be allowed for the reading of his paper, and but five minutes for any discussion This compelled crisp statement of fact and reasoning, and gave the Section a succession of fresh speakers This character of the papers and discussions renders their study by the worker in other fields easier and more attractive

Papers discussing portions of one general subject are found placed in such logical order as to be discussed and studied together as well as separately Thus incipient cataract, the operative treatment of immature and some forms of zonular cataract, and the operation for secondary cataract formed one group

Then we find a group of papers discussing many points respecting plastic operations of the eye, the restorations of the eyelids with sliding flaps, transplantations of skin in plastic operations on the eyelids, skin grafting in ectropion and entropion, transplantation of a strip of skin into the intermarginal space, some cases of the restoration of the eyelids by plastic operation

Another series of papers treat of intra ocular diseases and injuries, as the evisceration of the eyeball, histologic and bacteriologic notes on cases of penetrating wounds of the eyeball, etc , hemorrhage into the retina and vitreous in young persons associated with evident disease of the retinal blood vessels, extensive colloid changes of the choroid, prognostic significance of albuminuric retinitis

There are many papers dealing with various points relating to the ocular muscles, altogether forming a timely discussion of many moot questions Among these may be mentioned the technique of tenotomy of the ocular muscles, the slight effects sometimes produced as the result of free tenotomies of the ocular muscles for heterophoria, the limitations of tenotomy of the ocular muscles, tendon advancement with a special indication for its employment, the indications for, advantages and technique of muscle shortening, strabismus, the extent to which recently suggested methods of muscular exercise should displace tenotomy in the treatment of heterophoria, practical points gained in the treatment of one thousand cases of insufficiency of the ocular muscles, hysterical affections of the eye muscles, and some remarks on the paralysis of the superior rectus muscle As in the other groups of papers, a discussion of many of the points made, added greatly to the aggregate value of all

Another group of papers discuss points respecting diseases of the orbit and the tarsal cartilages

Still another group discusses moot points on refraction of the eye and includes an elaborate report of a committee on the examination and care of eyes during school life

Finally, there are a considerable number of unclassified papers treating of living questions in ophthalmology In whatever manner regarded, the Ophthalmic Section for 1895 merits the attention of every worker in this field, and will prove helpful to many in other fields of medicine The methods and spirit of the Section must stimulate other sections to that which is best, and materially assist in raising the entire ASSOCIATION to the highest attainable standard, and so promote the real development of the entire medical profession It may interest those not members of the Section'to know that the volume of Transactions of the Ophthalmic Section, with the discussions complete, are now passing through the press, and can be obtained at the JOURNAL office for $1

QUIS CUSTODIET CUSTODES?

The New York *Medical Record* in one of its latest issues calls attention to the impropriety of the chief medical member of the New York State Lunacy Commission appearing on the witness stand as a paid medical expert in cases where insanity is involved Its exceptions are well taken, since the Lunacy Commissioner is an officer who may in that capacity have later to pass on the same cases He stands between the insane and the asylum authorities under certain circumstances, and his prejudging their case as an expert witness is in a way a violation of their rights as it is also a wrong to the public

In Great Britain, we believe, no asylum officer is legally permitted to testify as to the mental condition of a person who may afterward be committed to his care, or, at least, to have any share in the certification of his insanity for his commitment The rule is not a bad one as far as it applies to matters of commitment to the special charge of the testifying witness, though it should not be so widely construed as it is perhaps in England, so as to really exclude competent expert testimony where individual interest could play no part in making or modifying the opinion But if it is applicable to asylum keepers, it is still more so to those who are over them in a supervising capacity, and this, it would seem, ought to suggest itself to every one holding such positions. The presumption that such is the case is probably the reason for any lack of specific statutory provision to that effect

The really most essential and important function of a lunacy commission, and for this every State should have one, is a judicial one, and it should therefore command the highest legal and medical talent for the solution of the dubious questions relating to mental derangement that may come before it It should be the protector of the individual as well as of the public,and its members should keep themselves from all bias or precedent that can disadvantageously affect them in either of these relations, and as they are really in a sense, a court of last resort they should not put themselves on record as having opinions as to individual cases that can by any possibility come later under review by them

These, at least, would seem to be the only views that could be held on a full consideration of every phase of the case, by men with a high sense of personal honor But with what MR HOWELLS calls the "business ideals" of the present age, the sense of honor is a variable quantity, and many respectable and even estimable people fail to realize the higher signification of the term in all the practical relations of life In these matters, even if honor, which may seem to some a sort of medieval and aristocratic conception, does not appear to be involved, a strict sense of propriety which often amounts to the same thing and is quite akin to nature, should be cultivated and made to regulate conduct

A lunacy commission does not serve its full purpose by devoting itself to the regulation of expenses and the collection of statistics of insanity, these are the "tithing of mint, anise and cummin," and other things yet are the ' weightier matters of the law''

CONNECTICUT KEEPS "OPEN HOUSE" FOR QUACKERY

The profession of Connecticut has been unable to secure the same class of registration acts that obtain in many of the eastern States, which fact is alleged to be painfully felt in the competition of practice in the large towns The October issue of the Bulletin of the State Board of Health shows that a movement is on foot that will tend to correct the evil It says

The following action was taken at the last meeting of the New Haven Medical Association, having been proposed by DR MAX MAILHOUSE

WHEREAS, In consideration of the fact that large numbers of graduates of colleges, which in this State are recognized as legal and reputable, are being rejected by examining boards in other States where the possession of such diplomas is not in itself sufficient to entitle the holders thereof to practice, and

WHEREAS, As a consequence of the foregoing fact, this State has become the dumping ground of other States with respect to undesirable practitioners, and

WHEREAS, In our opinion it behooves the State for its own protection to guard against such invasion, it is

Resolved, By the New Haven County Medical Association, that the attention of the other county associations, the various State medical societies and the various committees on lists of medical colleges be called to this state of affairs, and that, pending legislative action, these committees be re quested to revise such lists that they conform to the tenor of these resolutions further be it

Resolved, That the State Committee on Legislation be instructed to advocate the amendment of the law, so that all candidates for registration be required to pass an examination, as is now the case in New York, Pennsylvania and many other States

Adopted by the New Haven County Medical Association at its semi annual meeting in Meriden, Oct 17, 1895

CORRESPONDENCE

The Rush Monument

MONTCLAIR, N J, Nov 18, 1895

To the Editor —I note among the bright paragraphs which as usual make up the column of Miscellany in your issue of the 9th inst, one relating to the monument which our friends, the homeopaths, propose to erect to the originator of their faith I observed also that you acknowledge that the regular profession is somewhat slow in building a monument to one of the pioneers of medicine in America, Dr Rush I could not help thinking as I read, that it is comparatively easy to accomplish anything when the faith, enthusiasm, *amour propre*, or self seeking of a number of people are directed *in one channel or toward one object*

There are many names in regular medicine beside that of Dr Rush which ought to be perpetuated and which will be perpetuated, with or without a monument so long as medicine is faithfully studied and honestly practiced In homeopathy, on the other hand there is only one name, that of a man, a foreigner, who like Mohammed was an enthusiast, if not a fanatic, whose *delirium du grandeur* led to the evolution of the tenets of the sect which now seeks to do him honor His memory does not need the monument He will never be forgotten Great is homeopathy and Hahnemann is its prophet!

Meanwhile, those of us whom a recent talented homeopathic writer dubs, "the dominant school" of medicine, had probably better concentrate our efforts and raise a monument to Dr Rush and also to the immortal Warren, as two typical *American* statesmen, patriots and physicians

Very truly yours, RICHARD C NEWTON, M D

Dr Gihon writes to contradict the story that his committee have been negotiating with the same sculptor as the 'homeopathic" people

The Passing of Hypnotism

SHAFTSBURG, MICH, Nov 20, 1895

To the Editor —In the JOURNAL of November 16, p 867, is an editorial, "The Passing of Hypnotism" The criticisms in said editorial seem well taken Some six or eight years ago this community was a witness of its effects as a psychic agent This note is penned, needlessly perhaps, to illustrate the correctness of your conclusions Hypnotism is, unquestionably, a dangerous agent, requiring a morbidity of mind for its manifestation Now to our case

A young farm laborer went to a public meeting where hypnotism was practiced by a traveling lecturer, as he styled himself The young man was hypnotized Next day he was excused from work because his employer discovered that, using his own language, ' He did not know what he was about" There was a condition of mental depression, a dullness, amounting almost to stupidity which lasted many months People who have seen him since I have, declare he has not yet recovered and never will An agent which requires a state of mind for its exhibition must be soon It seems degrading for scientific men to use the "tools" of "traveling lecturers" Its use seems not a little like "*Similia similibus curantur*" with the *curantur* wanting

G W CHROUCH, M D

Was It Leprosy?

SPOKANE, WASHINGTON, Nov 22, 1895

To the Editor —My experience with lepers would point to Dr McDougal's cases as being undoubtedly leprosy

In the Sandwich Islands many cases can be found to disprove Dr Ashmead's statement that "if they were lepers the mother would have been infected too"

Dr Geo L Fitch, of San Francisco, who was for some years medical officer at Honolulu and by whose courtesy I saw some hundreds of cases of leprosy, asserted that all the leprosy in the Islands among the natives was "syphilis run riot in a virgin race," and defended his position so vigorously that the Government sent to Germany for Dr Arnold to decide who was right This was necessary as all lepers are sent to Molakai to the leper settlement from which place only death can relieve them

Dr Arnold's decision was in keeping with the opinion of all the old time doctors in the Islands and was based upon months of careful research, and I am sure that if Dr McDougal's two patients were to go before any medical examining board at Honolulu they would be sent to Molakai without a dissenting voice Very truly,

D C NEWMAN, M D

Triplets

MILTON, KY, Nov 23, 1895

To the Editor —Mrs Wm H Meiers, a German, primapara, 31 years of age, gave birth to two boys and one girl on the 17th inst One, a boy, is still living, the other two having survived but a few hours

A woman in this (Trimble) County once gave birth to four children at one time S E HAMPTON, M D

BOOK NOTICES

Pediatrics, the Hygienic and Medical Treatment of Children By THOMAS MORGAN ROTCH, M.D Illustrated Philadelphia J B Lippincott & Co Cl, pp 1124 1896

As might be expected, coming from Harvard, our oldest university, the work is at once scholarly, painstaking and thorough It is divided into eighteen divisions as follows Division I three lectures, *a*, Introductory, (infant at term) *b, Fetal Circulation c*, Vernix Caseosa, II, Normal Development, (four lectures), III, Hygiene of the Nursery, IV, Feeding (six lectures), V, Premature Infants, VI, General Principles of Examination and Treatment, VII, The Blood in Infancy and Childhood (four lectures), VIII Diseases of the Newborn (three lectures) IX, Diseases of the Skin, X, Syphilis, Erysipelas—the Exanthemata (five lectures), XI, Diseases of the Nervous System and the Myopathies (fourteen lectures) XII, Diseases of the Mouth, Nose, Naso pharynx, *and Pharynx (three lectures)*, XIII, Diseases of the Esophagus, Stomach and Intestines (three lectures, XIV, Diseases of the Liver, Pancreas, Spleen and Peritoneum, XV, Diseases of the Kidneys, Bladder and Genitals, XVI, Diseases of the Larynx, Trachea Lungs and Pleura (three lectures), XVII, Diseases of the Heart and Pericardium (two lectures), XVIII, Unclassified diseases viz, rhachitis scorbutus, rheumatism purpura diabetes tuberculosis, epidemic influenza diseases of thyroid gland diseases of the cervical lymph glands parotitis diseases of the ear

As will be seen the book consists of fifty three lectures feeding and on "the blood in infancy and childhood" without not only realizing what immense strides have been taken in the study of pediatrics in the last fifty years, but when the various incubators for premature births, and apparatus for preservation and sterilization of food are considered, but wondering what the world is coming to At this writing our eyes happen to fall on two old volumes, Farre, "*Maladies des Enfants, de la Naissance a la puberté*," (diseases of children from birth to puberty), Paris, 1847 And in these two closely printed volumes, in which everything relating to the medicine and surgery of childhood is stated, there is not one line on hygiene, excepting the appendix which is given up to "the physiologic education of young children," and in which the question of milk is indeed considered, but how diffusely! How crude the methods of milk examination compared with those figured in Rotch's book, and not a line on preservation, modification or sterilization of milk! How the learned Farre would stare at the proposition to count the blood corpuscles, to estimate the red and white and the hemoglobin!

The last half of this century may well lay claim to precision in method, to accurate knowledge in physiology of development, to direct therapeutic measures, and to its great and crowning glory in advanced preventive medicine may the next half century show equally great advances! We accept the book of Professor Rotch as in the foreground of the existing knowledge of pediatrics in the closing years of the nineteenth century The decimal system of dosage and of weights and measures is used throughout the book

We can not close this notice without complimenting the publisher on the excellent style of the volume and the very handsome illustrations

The Principles and Practice of Medicine Designed for the use of Practitioners and Students of Medicine By WM OSLER, M D Second edition New York D Appleton & Company Cl, pp 1143 1895

This excellent text-book has so soon passed to its second editon that it must be accepted that a discriminating profession has given its judgment in its favor, and indeed it is well worthy of the generous reception it has met with from whatever standpoint we view it This edition has been carefully corrected and many additions made Nor is the increase in bulk due to mere padding, for a comparison with the former will easily show that the additions are such as the progress of modern science have brought to the front The work is divided into eleven sections as follow

I, Specific Infectious Diseases, II, Constitutional Diseases, III, Diseases of the Digestive System, IV, Diseases of the Respiratory System, V, Diseases of the Circulatory System, VI, Diseases of the Blood and Ductless Glands, VII, Diseases of the Kidneys, VIII, Diseases of the Nervous System, IX, Diseases of the Muscles, X, The Intoxications, Sunstroke, Obesity, XI, Diseases Due to Animal Parasites

There is everything to praise and little to find fault with in this book We can not in the space of a mere notice undertake to write a criticism of so exhaustive a work, but we think when the next edition appears the distinguished author will take a less pessimistic view of the antiseptic and eliminative treatment of typhoid fever, (p 40) and he will at least refer to the syphilitic forms of myositis, (p 1050)

Handbook of the Diagnosis and Treatment of Skin Diseases By ARTHUR VAN HARLINGEN, PH B, M D Third edition, enlarged and revised, with 60 illustrations Philadelphia P Blakiston, Son & Co 8vo, cl, pp 577 Price $2 75 1895

This handbook takes up the various diseases of the skin, in alphabetical order, without regard to classification, an arrangement which although very convenient, necessarily gives rise to some overlapping, and causes the reader to make various digressions to other pages when reading on any particular topic For students preparing for examination, and for practitioners as a ready reference book, it be found very useful It is to be regretted that all the p scriptions, very numerously dispersed throughout the v ume, are written in the old style, and that the decimal s tem is entirely ignored When the new British Pharma pœia shall make its appearance, it is understood that t decimal system will be adopted and then there will be pharmacopœia in any language adhering to the old syst The trend of modern science in all departments is t universality, and it is a pity to see a *new* book so persis ently looking backward in this matter

Precis de Manuel Operatoire Par L H FARABEUF, Profess a la Faculté de Médecine de Paris, Fin de l'Ouvrage (p 69 à 1082) Résections—Appendice Aout 1895 Paper, 8v Paris G Masson 1895 [From P Blakiston, Son & C Philadelphia]

In 1872 Farabeuf commenced the work by a book on lig ture of arteries, which was soon followed by the second bo which was on amputations[1] In 1893, the first and secon books, which had reached respectively the fourth an fifth editions, were included in a single volume and the on now under consideration is the third book, and is devoted t resections, with exception of an elaborate appendix in which is discussed the subject of trephining, excision of nerves of the face, œsophagotomy, tracheotomy, symphseotomy, ischio pubiotomy, coccygeotomy, sacral luxation, recto-vaginal fistula, exstrophy of the bladder The volume concludes with a program of an operative course whereby with four cadavers, four students may accomplish a fairly complete operative course in eighteen séances The work has not described *all* the recent operations, as the author pathetically says, but he has described enough of them to answer all practical purposes, and the remainder he will leave to some younger man

Those who read French will enjoy the candor and quaint expressions of the author, which serve to enliven the pages of the handbook The illustrations are excellent, and as a whole the work is a notable addition to the literature of the subjects within its scope

Principles of Surgery By N SENN, M D PH D, LL D Second edition Thoroughly revised Illustrated with 178 wood engravings and colored plates 8vo, cl, p 656 Philadelphia The F A Davis Company London F J Rebman 1895

The growth of knowledge of surgical pathology since 1890 is so great that a revision of the work was necessary The great learning and vast clinical experience of the author are shown at their best in a work of this sort, and while the book has been revised to date by the addition of new matter and new illustrations, the arrangement remains the same as in the first edition For an elaborate review of the first edition, by Prof Christian Fenger, see this JOURNAL, Feb 14, 1891, vol XVI, 1891, p 250 The book is destined to hold the boards as a text-book for some time to come, and with justice, for it is a fair and exhaustive exposition of the teaching of the day on the subjects of which it treats We welcome the volume to our library as the latest and most mature thoughts of the distinguished author on the fundamental principles of the science and art of surgery

The Medical Register of New York, New Jersey and Connecticut 1895-96 Vol xxxiii Published under the supervision of the New York Medico Historical Society JOHN SHRADY, M D, editor New York and London G P Putnam's Sons

This annual volume of 250 pages, well printed and bound, gives much valuable information regarding the status of the profession in one of the eastern medical centers that is obtainable in no other form An arrangement of material better classified than in the earlier issues renders reference more ready, while the somewhat more complete chronological record and the severer taste of the obituary notices impart the air of a closer attention to the historical element

---

[1] This was translated by Dr Jno D Jackson, of Philadelphia, in 1874

The list of physicians of New York and Brooklyn shows many changed addresses, and many removals to outside localities Evidently the gradual change of the rental year in the great cities of the East from May to October, and the apartment system of merely monthly responsibility to the landlord, are bearing fruit in the medical as well as in other callings

The Physician's Visiting List (Lindsay & Blakiston's) for 1896 Forty-fifth year of its publication Philadelphia P Blakiston, Son & Co

This well known visiting list makes its forty-fifth annual appearance with the same clean pages and excellent arrangement that have characterized it for so many years A dose table has been compiled for this edition by Dr Geo M Gould, giving the doses of official and unofficial drugs in both the "English" and metric systems

The value of this list is unquestioned and the long period during which it has been published, is sufficient evidence if any were needed, of the popularity of the work

Urinalysis, including Blanks for Recording the Analysis and Microscopic Examinations of the Urine For medical practitioners, life insurance examiners and specialists Arranged by JOSEPH C GUERNSEY A M, M D Philadelphia J B Lippincott Company 1895

This book has 500 blanks for recording the results of examinations of urine, and by their use it is practicable for the physician to keep the record of an ordinary or of a minute examination, moreover it can be kept as a continuous record in long cases The blanks are preceded by a valuable practical chapter on apparatus and reagents, and the description of the various tests The book is indexed

PUBLIC HEALTH

Diphtheria in New Jersey —Owing to the alarming prevalence of diphtheria in Burlington, the Board of Health has ordered that all public schools be closed Consequently the doors were shut for an indefinite period The infant department of one of the Sunday schools has also discontinued its sessions for the present There have been thirty cases reported to the Board of Health, seven of which have resulted fatally Every possible measure is being taken to stamp out the disease Twenty-one cases of diphtheria have been reported to the Trenton Board of Health within four days, and of these four have proved fatal There were forty-eight cases of the disease reported last month

The Abolition of the Contaminating Slate —War against the school slate and pencil has been declared. Following the example set by the New York City Board of Health, calling upon the school authorities to abolish the use of slates on the ground that they spread contagion, comes the adoption of a resolution by the Mount Vernon Board of Education to the same purpose and providing for the use of pads of paper instead The alleged reasons for this action, in addition to the objection to the slate from a sanitary point of view, is that paper is now cheap pads now being sold which are suitable for school purposes for from 2 to 5 cents each Public school and health authorities in many cities and towns now have the subject under discuss and will probably likewise decree that the slate and slate pencil must go These hitherto useful articles will now be of value only to receive "spirit messages" from the other world through so-called mediums

Variola and Vaccinia, their Manifestations and Inter-relations in the Lower Animals —Copeman (*Journal of Pathology and Bacteriology*, Vol ii, No 2) concludes his researches concerning the above subjects in the following propositions

1 The organisms, to which the specific action of variolous and vaccine lymph is due, are, as yet, undiscovered

2 Although this is the case, all the most reliable evidence, experimental and otherwise, is in favor of the organisms of these two diseases being identical in nature, the phenomena of vaccination being most probably due to an attenuation of the virus, caused in a similar manner to that witnessed in chicken cholera and other diseases by sojourn in the tissues of an animal which is more or less refractory

3 Monkeys react to inoculations of variola and vaccinia in a similar manner to the human being, and therefore afford valuable means of controlling the results of experiments on the mutual relationship of the two diseases

4 It is possible to isolate from vaccine (and also to a less extent from variolous) lymph a number of microörganisms, none of which, however, have anything to do with the specific action of the lymph

5 These bacteria belong, in great part, to that class which is concerned in the process of suppuration, although others both pathogenic and non-pathogenic in nature, may be present also

These "extraneous" may be destroyed, if present by the following method of treatment which Copeman, like others, found would preserve the lymph unimpaired for an indefinite period, indeed, its specific activity so far from being destroyed, may actually become intensified, the lymph is mixed with a certain proportion of (75 per cent) glycerin in distilled and sterilized water prior to storage in capillary tubes which latter also had been sterilized by heat There seems to be no doubt but that the glycerin method of storage of lymph offers the easiest solution of the problem of securing an aseptic vaccine virus

Health Reports —The following health reports have been received by the Supervising Surgeon General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Louisiana New Orleans, November 9, to 16, 17 cases, 2 deaths
Michigan Detroit and Rochester, November 9 to 16 smallpox reported present
Tennessee Crittenden County, October 23, 1 case, Shelby County, November 13, 1 case

SMALLPOX—FOREIGN

Cairo October 22 to 28, 1 death
Dublin November 2 to 9, 2 cases
Guayaquil October 4 to November 8, 5 deaths
Hamburg November 2 to 9 1 case
Glasgow November 2 to 9, 6 cases
London November 2 to 9, 1 death
Madrid October 29 to November 5, 4 deaths
Marseilles November 21, smallpox epidemic
Montevideo October 12 to 19, 3 cases
Nogales November 9 to 16, 1 case
Odessa October 26 to November 2, 5 cases, 2 deaths
Pernambuco September 28 to October 12, 300 cases, 81 deaths
Prague October 19 to November 2, 5 cases
Rio de Janeiro October 12 to 19, 69 deaths
Rotterdam November 2 to 9, 2 cases
St Petersburg October 25 to November 2, 7 cases, 2 deaths
Tuxpan November 2 to 9, 1 death
Warsaw October 26 to November 2, 1 death

CHOLERA

Bombay October 15 to 29, 4 deaths
Calcutta September 28 to October 19 86 deaths
Egypt To November 9, 658 cases 496 deaths
Osaka and Hiogo October 12 to 19, 6 cases, 3 deaths
Tangier October 1 to 31, 1000 cases, 800 deaths

YELLOW FEVER

Cienfuegos November 10 to 17, 3 deaths

Guayaquil October 4 to November 8, 3 deaths
Perambuco * September 28 to October 12, 30 cases, 3 deaths
NOTE —The U S. Consul at Pernambuco, Brazil, writes that there is "more fever than has been known during the past twenty years"

NECROLOGY

RICHMOND LENNOX, M D , of Brooklyn, 34 years old, a specialist in diseases of the eye, died November 14 He was a graduate of the New York College of Physicians and Surgeons in the class of 1882 He was surgeon to the Brooklyn Eye and Ear Hospital, and also to the Kings County Hospital He was a member of the New York Ophthalmological Society and the Kings County Medical Society He was a member of the Hamilton, Lincoln, Carlton, Crescent and Whist Clubs He leaves a widow and two children The cause of his death was immediately due to cerebral embolism, occurring about twelve hours prior to his decease, he had for twelve years been the subject of chronic endocarditis

W HERBERT DUNLAP, M D , of Syracuse, N Y , November 11 He was born in that city in 1853, and was graduated from the Syracuse University in 1875 He received his degree in medicine from that institution three years later He had made a specialty of dermatology for the last ten years

JACOB MENDEL, M D , age 50, died November 12 He was graduated at Breslau, Germany For the last twenty-three years he had practiced in Milwaukee and was noted for his scholarly attainments His last illness was of short duration

——A J Freeman, M D , of Macon, Mo , November 23——Henry B Callahan, M D , of Leavenworth, Kan , November 23, aged 74——J E Chambers, M D , of Chicago, November 24, aged 35——Thomas Flournoy, M D , of Richmond, Va , November 20——Davis M Hammond, M D , of Evansville, Ind , November 18, aged 42——D F Lindsay, M D , of Noblesville, Ind , November 21, aged 77

MISCELLANY

Dr C F Scott, the State Veterinarian of Wisconsin, says that when the golden-rod is eaten by horses, it produces a fatal disease simulating tuberculosis

The Post-Card Dun —The *Cincinnati Medical Journal* reports that "Dr J W Morgan, of Cadiz, Ohio, has been arrested for having sent a dun to a former patient written on a postal card"

The American Journal of Surgery and Gynecology has been removed to St Louis, from which place the December number (vol VIII, No 1) is just issued Dr Emory Lanphear, Professor of Surgery in the Woman's Medical College, has been appointed editor in chief

The Committee of the Pasteur Institute has unanimously chosen M Duclaux, former subdirector, to succeed M Pasteur as director, and Dr Roux as subdirector of the Institute M Duclaux, who is a professor at the Sorbonne, has been connected with the Pasteur Institute since its foundation

Population of Japan —The Department of State has received advices from Japan stating that the population of that country is estimated to be 42,000,000, plus 3,000,000 for the newly added territory of Formosa Records of the population of Japan have been kept from the time of the seventh century, in 610, A D , the number was recorded as 4,988,842

Professor Koenig —It is now definitely announced that Koenig is to be called from Göttingen to fill the vacancy in Berlin caused by the death of Bardeleben Koenig is now 64 years of age, one of the most distinguished leaders of scientific surgery of the present, and widely known through his text-books on general and special surgery —*Deutsche Medicinische Wochenschrift*, Oct 31, 1895

New Method for Differentiating Antifebrin, Phenacetin, and Antipyrin —For this purpose warm a small quantity of the powder to be examined in a test tube with a small quantity of chlorid of zinc Antifebrin thus treated gives out aromatic vapors, phenacetin, a sharp odor, resembling that of acetic acid, antipyrin, one resembling that of sulphid of carbon —*Nouveaux Remedies* from *Pharm Zing* , No 63, 1895

Medical College Recognized —The Connecticut law concerning the practice of dentistry has been amended by the insertion of the words "or medical college," placing the holder of a diploma or other certificate of honorable graduation from a medical college having a department in dentistry, on the same footing with the holder of such document from a reputable dental college

Madame (Doctor) Chellier —The French journals state that Madame (Doctor) Chellier of Algiers, North Africa, has been appointed by the Governor of Algeria to make a special investigation in the outlying province She is to visit villages, study the condition of the Arab and Kabyle women, among whom no male physicians are permitted by Mussulman law, and introduce such measures as will alleviate their sufferings

A Butcher Became a Surgeon —An agent of the New York County Medical Society has made a case against "Dr" Adolph Grundman, who came to this country two years ago and established himself as a butcher Later he went into partnership with a registered physician A female detective, also an agent of the County Medical Society, says that Grundman prescribed for her He has been held for trial in a police court charged with practicing medicine illegally

Chlorin in Typhoid Fever —Dr R W Wilcox (*American Journal Medical Sciences*, September, 1895) in an interesting article on the use of chlorin in typhoid fever, after describing the method of preparation gives his conclusions as follows -

1 Chlorin can be safely administered until complete disinfection of the alimentary canal is obtained

2 Under its use the tongue becomes cleaner, the appetite and digestion better, fever lower, and the stools devoid of odor

3 The general strength, the intellectual processes, and nervous conditions improve

5 The disease is shortened in duration, and usually proceeds to rapid and complete recovery

Can Demand Services of State Veterinary Surgeon —The State Board of Health, it has been provided in Missouri, may demand of the Secretary of the State Board of Agriculture, through their President and Secretary, the services of the State Veterinary Surgeon to aid them in the inspection of such infectious or contagious diseases in live stock as are transmissible to the human family, and in the examination of meats, milk and foods, when in the judgment of said State Board of Health the assistance of this officer is necessary

Staff Surgeon Steuder of the German Army has had a considerable experience with African bilious fever According to *Illustrated Africa*, he has found that this fever seldom attacks men on the march or engaged in hard work, but seizes them when they are at rest By examining the blood the fever may be detected before it declares itself, as the deficiency of hemoglobin is marked, and may then be readily cured on the spot If too much hemoglobin is lost, the only thing to be done is to send the patient to Europe or some healthy climate In one case he made a cure by the transfusion of healthy blood into the patient's veins

A Medical Explanation —From *The Watchman* "Doctor" said an old lady the other day to her family physician, ' can you tell me how it is that some folks are born dumb?" "Why hem, certainly, madam," replied the doctor "It is owing to the fact that they come into the world without the power of speech" "Dear me!" remarked the old lady, "now just see what it is to have a medical education! I've asked my husband more than a hundred times the same thing, and all that I could get out of him was, 'because they are'"

New York State Association of Railway Surgeons —This Association held a convention at the New York Academy of Medicine on November 12 under the presidency of Dr R S Harnden of Waverly The subject of the presidential address was the establishment of hospitals by the railway corporations and their employes, acting jointly An election of officers for the year 1895–96 resulted as follows President C S Parkhill, of the Erie Railroad, First Vice President, I F Valentine of the Long Island Railroad, Second Vice-President, J K Stockwell of the Ontario and Western, Secretary, C B Herrick of the Delaware and Hudson Railroad, Treasurer, Theodore S Mills of the Ontario and Western, Chairman of the Executive Board, Dr George Chaffee

Wooden Diagnosis With Up to Date Therapeutics —Certain medical men of London are said by *Popular Science* to be backing up the following doubtful expedient for the repression of the patent medicine business Certain wooden figures have been put up on the nickel in the-slot principle The figures are shaped like a man, with holes in every part of the body labeled with the diseases that usually affect that part For headache you find the proper slot so labeled in the head of the figure, and drop in a penny, out comes an inexpensive but efficient prescription that can be filled by any druggist These prescriptions are said to be gotten up by prominent doctors and are very good and useful One object of this device is to make medicine cheaper to the poor and restrict the use of dangerous proprietary mixtures The notice reads more like a bit of journalistic enterprise than a fact

Change in Arizona Dentistry Law —The law regulating the practice of denistry in Arizona has been amended, requiring those who wish to engage therein to furnish satisfactory proof that he or she has two years of practical experience in the practice of dentistry And any applicant, it is further provided, presenting a diploma from a reputable dental college and a fee of $5, not returnable, may be granted by one or more members of the board, upon approval of the president, a temporary license to practice dentistry in the Territory until the next meeting of the board, at which time it shall issue to the applicant, providing the applicant shall have furnished satisfactory proof that said diploma was issued in good faith, to him or her, a practitioner's certificate entitling the applicant to practice dentistry in Arizona The proceedings of the board shall at all times, instead of at all 'reasonable" times, as heretofore, be open to public inspection

Dr Edward Berdoe, a practitioner of London, has written in the *Nineteenth Century* an article on the miracles at Lourdes, to which place he went in the attitude of a reverend skeptic He saw a vast army of paralytics and consumptives, idiots, the lame and blind. The supplicants at the grotto kneel for hours with arms outstretched, wrapped in devotion, and often in ecstacy The spirit of devotion is intense, it exalts the whole organism and serves of itself to explain much of the thaumaturgy That wonderful effects are wrought at Lourdes is unquestionable Purely dynamic diseases are cured, but not organic maladies Ulcers and tumors may be caused to disappear, if such lesions be of the same nature as paralysis and other disorders of motion and sensation, which are commonly considered to be the sole field for the influence of the faith cure Dr Berdoe believes that similar cures have been wrought in all ages, and quotes Greek tablets testifying to wonderful cures of blindness through the agency of the gods

Electrolytic Chlorate of Potash by the Ton —The *Chemist and Druggist* has an article on the progress made in Europe in the electrolytic manufacture of chemicals, in which is conveyed the prediction that the United States will take the lead in the alkali industry of the coming decade Hitherto the only important chemical that has been produced by electrolysis has been the chlorate of potash, but it can not be long before other substances will be made by that process The basis of the remarks of the journal above referred to has been a report by a French chemist, a part of which is given below

In *Le Moniteur des Produits Chimiques*, M Désiré Korda gives a sketch of the application of electricity to chemic manufacturing processes, referring particularly to the manufacture in Sweden and Switzerland of chlorate of potash, which, so far, is the only important alkali product made by electrolysis M Korda thinks that it is only a question of a few years before the entire alkali industry will be revolutionized The United States, he believes will then become the leading manufacturers of chemicals, while in Europe the industry will have its chief centers in Switzerland, Southern France, and Sweden—the countries where powerful and cheap water power are in close proximity to large consuming markets The Swiss chlorate of potash factory has been at work for nearly five years, the motive power being a waterfall 70 meters high As yet, of the total yearly European output of about 8,000 tons of chlorate of potash, over 5 000 tons are contributed by the United Alkali Company The electrolytic process in use in Switzerland is based upon Gall and Montlaur's process in which concentrated solution of chlorid of potash is decomposed in a double vat, divided by a diaphragm, but so connected to insure regular changing of the liquid from the negative to the positive compartments The electrolized solution is heated from 45 to 55 degrees C, thus changing hypochlorite into chlorate The cathode is of iron or nickel, the anode of platinum or of iridio-platinum The current is equal to 50 amperes per square decimeter of electrode

The Pineal Body —In *Popular Science News* for October, Anna Hinrichs presents an illustrated article on the comparative anatomy of the pineal body Her thesis is, that this body or "gland," is the rudimentary third eye of man and all vertebrates The central point of our brain, which so long has remained a mystery to the student of human and comparative anatomy, now appears as the rudiment of a third eye, overgrown and depressed by the immense development of the brain In other words, at the expense of a third eye man has secured his brain, the organ of intellection This discovery is not only very interesting, but also remarkably instructive, since this rudimentary third eye of man was looked upon by Descartes as being the seat of the soul

"In closely examining the skulls of certain lizards, it was found that near the top of the head under the dark opaque skin, and often in the very bone an almost perfect eye exists, though no ray of light ever could reach it Such an eye is represented in the upper figure of this cut This eye shows a crystalline lens, a retina of very complex structure, and an optic nerve, in fact, all the essential parts of a perfect eye But being covered by the opaque skin of the animal, it is absolutely useless If this optic nerve is traced to the brain, it is found to connect the eye with the so called pineal gland of the brain This pineal gland is in no sense of the word a real gland, but a definite portion of the nervous tissue of the brain, invariably located just back and partly over the cerebrum, and in front of the rounded brain mass which generally is considered to correspond to the corpora quadrigemina in man"

It is probable that this third eye was, at an earlier stage of development, not rudimentary but in constant use A moderate modification—namely, a transparent integument—would suffice, this is exactly the condition of the normal eyes in reptiles to-day, the skin covers them, but it is transparent where it passes over the eye In the skulls of some of the gigantic reptiles of the earlier age of this globe, paleontologists have long ago found a large round perforation Probably this was the socket of the third or pineal eye of the ichthyosaurus, the plesiosaurus and the labyrinthodon But a much more important conclusion must be drawn from this discovery, namely, that in all vertebrates, even including man, the traces of this third eye remain to this day The pineal eye of lizards being connected with the large pineal gland of the same, it would seem that the pineal gland itself is but the nerve center or optic thalamus for this third eye In all reptiles and amphibia, the pineal gland is large, so it is also in fishes In the higher vertebrates, the cerebrum developes very highly, overgrowing the posterior portions, under the influence of which preponderance of the cerebral mass, the pineal body is more and more repressed into rudimentary forms But it remains with obstinate pertinacity It is even always present in man—though here only of the size of a pea and rudely resembling a pine cone in shape It seems also degenerate in structure, having hardly any nervous tissue These facts of form and structure have given rise to its name, that of pineal gland The position of the pineal gland in man is almost in the very center of the brain The pea-like, rounded mass attracts attention when the third ventricle of the brain is opened It is almost free, being held in place by two light, stalk-like bands or peduncles which connect it to the cerebrum anteriorly The gland, so called, is rather vascular, and contains also crystalline mineral matter, the so-called *acervulus cerebri*, consisting mainly of phosphates

Society Notes

North Texas Medical Association—The semi-annual meeting of the North Texas Medical Association will be held in Greenville December 10, 11 and 12 There are nearly forty papers on the program, and an instructive meeting is expected

The Chicago Gynecological Society, November 22, had an open meeting Dr Wathen, of Louisville, was an invited guest

Grayson County Medical Society—The following preamble and resolutions were unanimously adopted by the Grayson County Medical Society at its regular meeting held in Sherman, Texas, November 5

(Signed) J H Glasscock, M D, President
T M Taylor, Secretary

DEPARTMENT OF PUBLIC HEALTH

Whereas, This Society believes that a Department of Public Health under control of a Secretary who should be a *member of the Cabinet* of the President of the United States, is necessary to the welfare of this country, therefore be it

Resolved, That this Society indorses the bill now pending to establish such Public Health Department, and requests our members of Congress to support said bill and aid in its passage

Resolved, That the Secretary be requested to transmit a copy of the foregoing preamble and resolutions to our Senators and Representatives in Congress

Resolved, That this preamble and resolutions be spread upon the minutes of the Society

Hospital Notes

Bequests for Hospital Purposes at Newark, N J—The will of Mrs Anna Skinkle, daughter of the late Jacob Skinkle, leaves $3,000 to the Orange Memorial Hospital for the endowment of a child's bed in memory of her deceased son, William Skinkle Allen She gave to her husband one-half of the residue of her estate, and provided that under certain conditions, the remaining one-half of her residuary estate should be used for the foundation of a general hospital for sick and infirm persons It is to be located in or near Newark, is to be forever under Protestant control, and is to have connected with it a chapel for religious services, but such services are to be of an undenominational character To provide against any miscarriage of her wishes in the hospital matter, Mrs Allen says in her will that if for any legal or other reason the gift for a hospital, as made by her, is declared invalid, she gives it (one half of her residuary estate) "to the Mayor and Common Council of Newark for the erection of a wing or annex to the City Hospital, the same to be known as the Skinkle Memorial Annex'"

The Day-Kimball Hospital at Putnam, Conn, was dedicated November 10——St, Anthony's Hospital at Rock *Island, Ill, was dedicated and formally* opened November 19——The committee appointed by the last Iowa Legislature to adopt plans and erect a hospital for the insane at Cherokee held a meeting in Des Moines November 20 and adopted plans for the institution which will cost $1,000,000——*The twenty seventh* anniversary of the New York Presbyterian Hospital was celebrated November 16 The annual report showed the expenses of the *hospital during the* year were $165,692 12 and the receipts from patients were $29,534 61 Donations were received amounting to $12,099 30, while the income from investments amounted to $27,857 29——The Junior Society of Mount Sinai Hospital, New York, has been *organized* and promises to be one of the leading charitable societies of that city——The Ladies' Aid Association, of St Mary's Hospital, Brooklyn N Y, held a promenade concert *and reception November 27*——The Woman's Board of Governors of the Orange *Memorial* Hospital will erect an isolated ward for consumptives——It is alleged that owing to difficulties that have arisen between the Board of Trustees and the medical staff of the Phœnixville, Pa, Hospital, the latter have resigned in a body——The Silver Cross Hospital at Joliet was opened November 16

Detroit Notes

Dr S L Wyszynski—A fatal accident happened at the Buchanan St crossing of the Michigan Central Railroad, about 5 o'clock on the evening of the 21st inst, resulting in the death of Dr S L Wyszynski, one of the leading physicians of the Polish district of Detroit The deceased was born in 1854 *in a province of* Russian-Poland, and was educated as a physician at Academies at Warsaw and St Petersburg Four years ago, after having served fifteen years in the Russian Army, he came to America and located in Chicago, practiced there two years, and then moved to Detroit, where he continued a very successful professional career up to the day of his death A wife and four daughters survive him, two of the daughters being at home and two in Russia, the eldest one, Mrs Wanra Nicholi, being the wife of a lieutenant in the Russian Army

Wayne County Medical Society at its regular meeting Thursday, November 21, listened to a very interesting paper by Dr Dayton Parker on "Diphtheria"

The Detroit Medical and Library Association listened to a paper by *Dr F Pettyjohn* of *Alma*, Mich, entitled, "Notes on Differential Diagnosis and the Treatment of Neurasthenia," at its meeting of *November 18*

The Academy of Medicine at its meeting November 5, heard a paper from *Dr Hal C* Wyman on "Fractures of the Neck of the Femur"

Health Office Report for week ending November 23 deaths, under 5 years, 25, total 92 Births, male 47, female 35, total 82 Contagious diseases week ending November 23 diphtheria last report 25, new cases 27, recovered 10, died 8, now sick, 34 Scarlet fever, last report 13, new cases 6, recovered 4, died none, now sick 15 Smallpox, last recovered 3, new cases none, recovered none, died one, now sick 2, also one case from Hamtramck, and one from Rochester, Mich, were taken to the smallpox hospital

Philadelphia Notes

The Jefferson Medical College has purchased an adjoining property at Tenth and Medical Streets, and will in the course of next year open a laboratory building, five stories in height, fitted up with all the modern apparatus for technical teaching in physiology, bacteriology and pathology The first floor is to be used for dispensary work

The Medico-Chirurgical College has purchased the adjoining properties on Cherry Street down to the corner of 17th Street, so that its buildings when completed (including the College Hall, the Hospital and Maternity) will extend an entire square from 17th to 18th, on Cherry Street

A new clinical amphitheater is in course of erection on the premises of the hospital An amicable adjustment of strained relations has been made with the Philadelphia Dental College Both schools have used the lecture halls conjointly and carried on their dispensary service in the same building, for several years, but the classes have now grown too large for this arrangement to continue, and after next term the Medico Chirurgical will dissolve the arrangement and will occupy the premises alone, the Dental College seeking quarters elsewhere Dr J C Bonning has been elected Professor of Anatomy and Surgery in the Philadel phia Dental College, succeeding to Dr Garretson's chair

Free Lectures on Bacteriology —A course of five weekly lectures, on Saturday afternoons at 3 o'clock, was begun at the Academy of Natural Sciences last week, (November 16) by Dr M V Ball

The City Bacteriological Laboratory —A protest has been made against the continuance of the bacteriologic department in its present location on the seventh floor of the City Hall Members of Council and others in fact wish to have the entire Health Department removed to a separate building so that they may not come in contact with medical inspectors in the elevators and lobbies It is asserted that the bacteriologic laboratory is much visited by the public, and visitors are shown guinea pigs and rabbits and "such small deer," in all stages of fatal infection with diphtheria, anthrax and other zymotic and contagious diseases There seems to be an inconsistency in the health authorities placing human beings under so-called quarantine at their own homes, on account of a child which is affected by these disorders, and on the other hand indiscriminately inviting visitors to the laboratory, where the Klebs Löfller bacillus is doing its deadly work on a score of inferior animals, which in addition to being made to suffer for the cause of science are also permitted to gratify a very unscientific curiosity

Polyclinic Hospital and School for Graduates —Dr A Larue Vansant has been elected Professor of Laryngology, and Dr James K Young Professor of Orthopedic Surgery in this school

The Trustees of the Woman's Medical College have appointed Dr James K Young Clinical Professor of Orthopedic Surgery

The Pepper Laboratory of Clinical Medicine connected with the Hospital of the University of Pennsylvania, 36th and Spruce Streets, will be formally opened Dec 4, 1895, at 3 o'clock, P M Addresses will be made by Drs J S Billings, Director of the University Hospital, and W H Welch of Johns Hopkins

Philadelphia Hospital —Dr Alfred C Wood was recently elected to succeed Dr Wm G Porter, on the medical staff of the hospital, the latter having resigned after nearly twenty-five years service Dr J Chalmers Da Costa was also elected to the surgical staff, thus increasing the number of surgeons to ten Dr Elizabeth L Peck was chosen to succeed Dr Clara Marshall on the obstetrical staff Dr Ernest B Sangree was made pathologist to the hospital

Municipal Authorities Supply Antitoxin —November 20 should be a red letter day in the Philadelphia Health Department, as it possibly marks a new era in medicine, for on that day the city of Philadelphia entered the lists among the manufacturers of medicine and distributed to the Municipal Hospital the first delivery of antitoxin, or diphtheria vaccine, of its own manufacture

A Colony Farm for Epileptics in Pennsylvania has been projected and a charter obtained from the courts Dr Wharton Sinkler, of Philadelphia, is the President of the Board of Directors It has been announced that a donation of $50,000 for building purposes has been promised, if a suitable site be obtained for a farm before the first of next January

Sohleich's Method of Local Infiltration and Anesthesia was recently brought before the Philadelphia County Medical Society by Prof Theophilus Parvin, and Dr Keen has done a laparotomy, a herniotomy and several other operations by this method, which is a substitute for general anesthesia in suitable cases Dr Morton and other surgeons also have operated successfully by local anesthesia

St Louis Notes

Mortuary Reports for the week ending November 23 deaths, 160, preceding week, 156, corresponding week of 1894, 148 Births reported, 233

Contagious Diseases —The Health Office reports for the week ending November 23 cases of diphtheria, 160, deaths, 20, cases of croup, 20, deaths 10, cases of typhoid, 11, deaths, 6, cases of measles, 10, cases of scarlatina, 12

The St Louis Medical Society —The scientific program on November 23 consisted of a paper on " A Phase of Traumatic Epilepsy," by ,Dr Frank R Fry, with discussions by several neurologists Dr Fry deprecated the common use of the word traumatic, as somewhat lacking in discrimination, and advocated the use of the term only in those cases of epilepsy where it could be shown that trauma had affected the brain directly or indirectly in a way to produce epilepsy His remarks were made anent two cases that had been reported as instances of traumatic epilepsy, in one of which the trauma had been a burn at the knee, and in the other a head injury, both of which had been cured by treatment of exciting foci outside of the brain itself, viz, treatment of the scar in one case and the removal of buttons of bone in the other

Dr A B Shaw in his discussion of the paper, emphasized the need there was of a constant reminder that epilepsy was merely a symptom, pointing out how various lesions of the brain might produce epileptoid manifestations He could not say that he was entirely in accord with the reader in his attempt to limit too sharply the use of the term traumatic, though he did not wish his position to be construed as opposing that taken by Dr Fry, since in his hearing of the paper he might have failed to gain a clear notion of the limitations Dr Fry advocated Dr C G Chaddock could see no reason why a case of epilepsy should not, for practical purposes, be called traumatic when its development could be shown to be related to an injury, no matter whether the trauma affected the brain directly or not If we were to reserve this qualifying word for only those cases of epilepsy in which injury to the brain could be demonstrated, it could be consistently used only where the brain had been actually examined, or where there were symptoms of focal lesions As the cases cited showed, it was well in any case to consider the possible operation of reflex influence even in those cases where the injury had been to the head As a suggestive allusion, reference was made to the possible path to the cortex of an irritative excitation of the dura, viz, through the peripheral neurons of the trifacial and the vagus A rather close relation of the fifth nerve to the vagal nucleus was assumed through its descending roots, and the proximity of the vagal nucleus to the convulsive area in the medulla was pointed out Was there any relation between this area and the vagal nucleus and cortex that could be of influence in the production of convulsive seizures? Though Binswanger had not produced epileptic convulsions by irritation of this area, tetanoid movements had thus been induced and at least its relation to the vagus was worthy of consideration in cases of epilepsy where a reflex through the trifacial or vagus was possibly in play The influence of predisposition to epilepsy in cases of a traumatic causation was emphasized, because there was seemingly an inclination to overlook it It was suggested that it was quite as influential in traumatic cases as in other varieties of epilepsy and this could not be ignored until a lesion that would invariably induce epileptic seizures had been demonstrated It would be interesting to know whether the findings in the urine and blood that had been demonstrated for so-called idiopathic epilepsy would hold good for epilepsy due to gross brain lesions The necessity to remember that general causes, such as a toxin in the blood, might induce Jacksonian seizures, was pointed out, for neglect of this might lead to an error in diagnosis Dr G C Crandall likewise laid stress upon the element of predisposition in epilepsy, no matter what the exciting cause, and he pointed out the bearing other signs and symptoms of a general neurosis might have upon the prognosis of operative procedures for the cure of convulsive seizures Dr Ludwig Bremer alluded to the findings of sclerosis of cortical and subjacent nervous tissue which he had been able to demonstrate in the few epileptic brains he had examined He emphasized the relation of epilepsy and hysteria, recalling the fact that it is often impossible to make a differential diagnosis between true epilepsy and hysterical seizures He was inclined to question whether there was not an hysterical element in so called reflex epilepsy Dr Keating Bauduy instanced several interesting cases of reflex epilepsy, mainly of genital origin, which rather pointed to an hysterical factor The general discussion was concluded by remarks from Drs Funkhouser and Jacobson

Washington Notes

HEALTH OF THE DISTRICT—From the report of the Health Officer for the week ended November 16, is taken the following abstract the general health of the city underwent a material improvement last week From 121 in the week previous, the mortality fell to 99, and the annual death rate per 1,000 inhabitants correspondingly declined from 22 8 to 18 6 There was no death reported by diphtheria, scarlet fever, measles or whooping cough There were 7 deaths from typhoid fever as compared with 8 by the last report, while those from consumption were over 50 and from other lung maladies 20 per cent less The birth returns amounted to 72, and those of marriages to 79, of which 44 were between white and 35 between colored persons

MEDICAL SOCIETY OF THE DISTRICT—At the meeting of the Medical Society held on the 20th inst, Dr H W Beatty reported a very interesting fatal case of dermatitis exfoliativa which was discussed by Dr B F McGuire Dr Behrend reported a fatal case of rabies in a lady patient, and Dr D E Salmon read a paper on the prevalence of rabies in the District of Columbia Both subjects were discussed by Drs V A Moore, Walter Reed, Forwood, Chappell, Lovejoy, Schaeffer and others Dr Acker reported a case of endocarditis following chorea in a young child

REPORT OF COMMITTEE ON STEAM RAILROADS (BOARD OF TRADE)—The committee on steam railroads and public safety are making war on steam railroads and endeavoring to bring about certain changes in grade crossings which will protect human life and limb In their report to the Board they give the following recapitulation of the killed and wounded during the past four years

BALTIMORE AND POTOMAC RAILROAD

	Killed	Injured
1892	6	7
1893	10	7
1894	5	11
1895	5	11
Total	26	36

BALTIMORE AND OHIO RAILROAD

	Killed	Injured
1892	6	5
1893	7	7
1894	1	6
1895	0	1
Total	14	19

Killed, 40 injured, 55, total 95

LETTER TO A WASHINGTON PHYSICIAN—The following letter bearing the stamp of the U S Senate, was received a few days ago by a prominent Washington physician

Dear Doctor—I enclose cheque for $—— This I fear (my memory being shy) still leaves a balance But then it is singularly appropriate that I should have a running account with you, inasmuch as it was always on account of a running that I called to see you Did you laugh? You get a cigar Confidentially, it takes a —— good natured man to joke about a doctor's bill Any man who can descend to that, would laugh while his teeth were being pulled

"Yours very truly, ——"

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from November 16, 1895 to November 22 1895

Major Joseph K Corson, Surgeon, leave of absence granted is extended twenty days, on surgeon's certificate of disability

Capt George McCreery, Asst Surgeon, is granted leave of absence for four months to take effect about Dec 10 1895

First Lieut Irving Wallace Rand, Asst Surgeon will report in person without delay to the President of the Army Medical School, for the course of instruction prescribed in General Order No 78 Sept 22, 1895 from Adjutant General's Office

APPOINTMENTS

To be Asst Surgeons with the rank of First Lieuts Nov 15 1895 Thomas Jellis Kirkpatrick Jr, John Hamilton Stone, Irving Wallace Rand

Powell Conrad Fauntleroy, to be Asst Surgeon with rank of First Lieut, Nov 15, 1895

RETIREMENT

Lieut Col Joseph R Gibson Deputy Surgeon General, retired from active service Nov 15, 1895, on account of disability incident to the service

PROMOTIONS

Major Justus M Brown Surgeon to be Deputy Surgeon General with the rank of Lieut Col, Nov 15 1895

Capt Daniel M Appel, Asst Surgeon, to be Surgeon with the rank of Major, Nov 15, 1895

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending November 23, 1895

Medical Director P S Wales, ordered to duty as member of retiring board, Washington, November 25, in addition to his present duties

P A Surgeon R P Crandall, detached from the naval laboratory, and ordered to the naval hospital New York

P A Surgeon Philip Leach, detached from the naval hospital, and ordered to the naval laboratory, New York

Marine Hospital Changes Official list of changes of station and duties of Medical Officers of the U S Marine Hospital Service, for the fifteen days ended November 15, 1895

Surgeon C S D Fessenden, ordered to proceed from Salem to Boston Mass, for physical examination, Nov 14, 1895

P A Surgeon D A Carmichael relieved from duty at St Louis Mo, and directed to proceed to Vineyard Haven, Mass, and assume command of Service, Nov 1 1895

P A Surgeon S D Brooks relieved from duty at Chicago Ill, and directed to proceed to St Louis Mo, and assume command of Service, Nov 5, 1895

P A Surgeon J H White, granted leave of absence for twenty three days Nov 5, 1895

P A Surgeon T B Perry, granted leave of absence for thirty days, Nov 11 1895

P A Surgeon J O Cobb to proceed from Pt Townsend to Port Angeles Wash as quarantine inspector Nov 1 1895

P A Surgeon J B Stoner to proceed from Detroit, Mich, to Baltimore, Md, for temporary duty, Nov 1, 1895

Asst Surgeon C H Gardner to proceed from San Francisco, Cal, to Chicago, Ill for duty, Nov 5, 1895

Asst Surgeon Norman Seaton, to proceed from Baltimore, Md, to New Orleans, La, for duty, Nov 1, 1895

Asst. Surgeon A R Thomas, to assume temporary command of Service at St Louis Mo, Nov 1, 1895

Asst Surgeon J B Greene, to proceed from Vineyard Haven, Mass, to Baltimore, Md, for duty, Nov 1, 1895

Change of Address

Beckett, J, from 879 Lake St to 283 Park Ave, Chicago
Carmichael, D A from St Louis, Mo to Vineyard Haven Mass
Caldwell J R from New Hamburg to Greenville, Pa
Dunbar, L L, from 500 Sutter St to 606 Sutter St, San Francisco, Cal
Gardner Mathew, from Sacramento to Southern Pacific Hospital Association, San Francisco, Cal
Miller R E from 3100 State St, to 3255 State St, Chicago
McIntyre, J H, from 623 Locust St to 710 Olive St St Louis Mo
Norbury F P from Jacksonville, Ill, to 1006 Olive St St Louis Mo
Penny H T, from Baltimore, Md to 1016 10th St, Washington, D C
Sharpe W F, from 500 Sutter St to 606 Sutter St, San Francisco, Cal

ŒSOPHAGEAL STRICTURE AND ITS SUCCESSFUL TREATMENT BY ELECTROLYSIS AFTER FORTY YEARS STANDING

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY W S WATSON, M D
(RIVERVIEW HOME SANATARIUM) FISHKILL-ON HUDSON, N Y

The symptoms of esophageal stricture are pretty generally known to the profession, the symptoms may and very often do exist for some time before the patient or the medical attendant realizes the gravity of the existing condition, they begin with difficulty in swallowing solids, especially meats, and when eating hurriedly, the trouble increases from day to day until only liquids can be swallowed with great difficulty After the stricture has existed for some time, the space above the point of stricture becomes dilated in the effort to swallow or retain food, and often the patient is led to believe that he has swallowed food when it will suddenly return If the stricture be low down, the food will remain much longer than if high up, persons suffering from esophageal stricture are always lean and emaciated The health gradually declines

In diagnosis of stricture of the esophagus, great care should be taken to determine the cause, for, if cancerous, no treatment can do much for the sufferer, hence in giving a prognosis we should know that we are not dealing with a cancerous obstruction

A stricture differs from a spasmatic closure, one taking months and sometimes years to develop so as to interfere greatly with the swallowing, while the other, the spasmatic, comes suddenly and disappears in like manner In the spasmatic form anti spasmatics relieve, in the other, medication does no good, in the spasmatic closure of the esophagus, a bougie passes to the stomach with but little or no resistance, if it does meet with any resistance, moderate pressure soon overcomes that resistance, with a fibrous or cicatricial stricture it is not so The bougie can with great difficulty be passed, if at all, paralysis will impede the swallowing and food may become lodged for want of power to swallow and be regurgitated, the passage of an ordinary bougie will readily determine this, in cancerous obstructions, the passage of a small bougie determines the fact by blood being upon the returned bougie and upon food regurgitated Once satisfied that we have a stricture to deal with, a cure may be assured, the patient being determined and having a reasonable amount of strength to endure a course of electrical treatment, which is not without some pain, a cure requiring from two to six months' treatment by electrical dilators once or twice a week

In the treatment it is necessary to have a good reliable galvanic apparatus with an evenly graduated rheostat and milliampèremeter, six or eight olive-shaped bulbs of as many different sizes, beginning with a three eight inch and increases two eighths each treatment, made preferably of aluminum and fitted with a deep screw thread to a copper wire that is covered with hard rubber insulation to protect the mouth and throat, shaft about sixteen inches in length, sufficiently *flexible to admit of some* bending, the better to enable one to follow the curves of the throat, yet sufficiently stiff to support some pressure, the bulbs or tips need be a perfect oval or olive, from the largest diameter in both directions, otherwise they are very difficult to withdraw and occasion unnecessary pain

Miss S, aged 62 years, had suffered from stricture of the esophagus since about 14 years of age, of a fibrous character, occasioned by a hard bit of apple becoming lodged in the throat and remaining there a considerable length of time, setting up inflammation and cicatricial formations at three different points, first just below the cricoid cartilage, another about one and a half or two inches lower, a third very low down Treatment was begun in September, 1894, using for exploration a small, somewhat flexible bougie which would not pass the first point of stricture The closure was so complete and had been for upward of twenty five years that it was impossible to swallow any kind of solids, and liquids were taken with the greatest difficulty, requiring frequently two or three hours to get enough down to sustain her The saliva would not take its natural course but was overflowing almost continually from the mouth, requiring the use of a handkerchief to absorb it every few minutes, I found it impossible to pass even the small flexible probe A small three eighths inch electrode was tried with the aid of 6 millimeters of current, attaching a small electrode to the negative side (here let me say that it is *highly important* that you be able to let on the current gradually to avoid the shock and fright), using a carefully devised rheostat (I find the Williams a most excellent one for the work), placing the pad, which is attached to the positive cord, to the back of the neck

Pass the bulb down to the first stricture, then have an assistant turn on the current gradually until 6 or 8 millimeters is reached, keeping up a moderate pressure for a few minutes, perhaps three to five, when the bulb is sure to pass A greater amount of current would probably pass the bulb through the stricture sooner, but it would be at the expense of tissue, by reason of the destructive character of a strong current when attached to the negative pole It is highly important that a dilating bulb be attached to the negative side, since it is the negative pole that softens by chemic action all tissues in contact, hence it is the one to absorb cicatricial formations and certainly has a salutary effect in cases of cicatricial strictures Treatment was given once a week for a period of six weeks At the second visit I succeeded in passing a three eighths-inch bulb through the three strictures, after which time the saliva did not overflow, nor were there any more spasmatic troubles when attempting to force down liquid foods, as had always or nearly always been the case At each treatment an eighth-inch larger sized bulb was used and passed, endeavoring at each sitting to pass through the strictures slowly, which was greatly interfered with on some occasions owing to the quite severe retching due to the bulb being passed down the throat We believe it highly important that a dilating electrode remain for some minutes in contact with the false tissues, in order that the electrical current may have time for action, the time in contact has all to do with the success of the treatment A rapidly passed electrical dilator is no great improvement over the old method of using dilators simply

After the sixth week, treatments were given twice a week, after the third month a one-inch bulb or electrode was passed, and I was informed by the patient, a few days after last Thanksgiving dinner, that she had enjoyed the first Thanksgiving dinner in upward of twenty-eight years She ate freely and without difficulty all semi-solids, even cake, pie and dressings, but no meats were tried, she being fearful of choking if she did Treatment was continued once in two weeks, continuing the one-inch electrode, and went no higher than 10 milliampères of current, five months from date of commencement of treatment she swallows with little or no difficulty, is still afraid of meat, but it could be taken with perfect safety, if well masticated We are unable to get the patient to continue the treatment longer, as she feels that her ability to swallow is good enough, however, we would prefer to continue the dilatation with the electrode for fully six months longer at greater intervals It is well to caution the patient as regards eating solids Abstaining from solid food has unaccustomed the stomach to such articles, so that serious stomach troubles may follow the indulgence of the ravenous appetite which is likely to follow such a long abstinence from solids

ELECTRO-THERAPEUTIC TECHNIQUE IN THE TREATMENT OF NEURASTHENIA AND NERVOUS PROSTRATION

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association, held at Baltimore Md, May 7 10 1895

BY G BETTON MASSEY, M D
PHILADELPHIA PA

The proximate purpose of electrical treatment in the group of conditions known as neurasthenia has been somewhat vaguely understood by different investigators, resulting in quite a variety of methods being employed Remembering the multiform phases of the affection itself, this is by no means strange, particularly when it is recalled that our knowledge of the pathologic processes underlying it is extremely imperfect and based mainly on deductions from therapeutic empiricism

Judging from published utterances and from the methods of treatment recommended, it is evident that most of the authorities agree with the original investigator, Beard, in regarding the disease as a perversion of function of the cerebro-spinal system of nerves Benedikt, Weir Mitchell and Rockwell, for instance, rely almost entirely on general faradic applications, apparently for tonic and revulsive effects, while Morton, Vigoroux and others employ static applications The currents used by them expend their force on the external moist layers of tissue, having insufficient density for effective penetration to deeper structures, and hence the therapeutic results must be due mainly to their action on the cerebro-spinal nerves and voluntary muscles

While it is likely that the Beard hypothesis of the nervous origin of neurasthenia adequately explains the secondary mechanism of these pathologic nerve fatigues, it is not so clear that the initial pathologic conditions arise in the cerebro-spinal system in any cases except those suddenly following mental shock or strain It is extremely probable that deficient innervation of the sympathetic system is a more important factor But whether primary or secondary, sympathetic nervous insufficiency may be constructively regarded as present in the majority of cases, accompanied by functional derangement of the organs that maintain a pure and healthful condition of the blood Flowing from this, come auto-intoxications, abnormal organic sensitiveness, etc

It is by no means denied that faradic currents may not produce effective results of therapeutic value on central organs and nerve structures, but it is clearly evident to the physicist that a sufficient density of either current can not be conveyed to them from the small electrodes and imperfect skin contacts still incorrectly employed by many neurologists in percutaneous applications of electricity The inch and inch-and-a-half disk electrodes are intended for localizing the current near the periphery, and are therefore properly employed in picking out and exercising groups of muscles in the limbs and trunk, but they are totally inadequate to convey any effective currents into organs situated in the cavities of the body

To reach and remedy these primary and secondary inactivities and pathologic fatigues of the abdominal nervous system, we need currents of volume and penetration, preferably galvanic currents, and that they may be carried painlessly to these deep-seated structures, large conducting pads must be used Fifty to 80 milliampères may be an ordinary application with such pads, and considering the rapid diffusion of the lines of current beneath the electrode, nothing less is likely to convey a sufficient density to the points desired By the large pads we are also enabled to use the most effectively stimulant faradic current, the primary, the large conducting surfaces minimizing the resistance to a point enabling low pressure and large volume inductions to be transmitted through the skin The method is monopolar, the indifferent electrode being applied to the back

An excellent form of electrode for both general and abdominal applications is made of brass wire sewn in a flat spiral to the upper surface of a piece of muslin The concentric turns of wire are about half an inch apart, the outermost turn ending in a free piece of wire which is coiled about a rheophore tip to make a friction attachment On the upper side of the muslin, and covering the wire, six layers of absorbent cotton are placed, covered with muslin or linen, the whole being then quilted through to make a compact pad The size of the indifferent pad should be about ten by fourteen inches The pad for the active pole is round and about seven inches in diameter When thoroughly moistened and with surfaces soaped, these electrodes furnish an ideal contact, so elastic as to fit any portion of the body surface, and when used for more than one patient they may be kept aseptic by daily immersion in boiling water

The maintenance of a thoroughly moist condition of the electrodes is an essential, in transmitting considerable currents through the skin with least resistance and pain, and if the active electrode, particularly, is kept well lathered with a soap like ivory soap, which I find to be the best lather-making soap on the market, as tested by comparative sensations under labile applications, the active electrode may be made to pass freely and almost painlessly over nerve points in a labile manner, evoking as full contractions of muscle groups as the faradic current, with added metabolic stimulation The same electrode is used for producing muscular contraction in the limbs and for abdominal applications, its exteme elasticity permitting a proper contact with the limb surface without the whole pad touching

The various procedures in general galvanic stimulation are as follows the patient, having disrobed, lies upon a blanket or sheet, both ends of which can be folded over the person The indifferent pad, lying on a piece of water proof sheeting, is placed under the small of the back and connected with the positive pole of the battery The active electrode, connected with the negative pole, is first placed on the abdomen, a lather is raised by moving it about, and 10 or 50 milliampères turned on through the controller Slow movements are made in the direction of the colon for several minutes, when the galvanic current is turned off and a primary faradic current turned on, also through the controller, and the same movements kept up for an equal time The arms and legs next require attention in regular order with the galvanic current, the active pad being placed in contact with the limb before turning the current on at the controller (and kept in contact until the limb has been finished and the current turned off) from 15 to 30 milliampères being enough to produce contractions if the pads be passed quickly over the nerve points

The immediate effect of this treatment varies with the condition of the patient If the case be one of great prostration it is advisable to have him or her rest awhile afterward until reaction has occurred, as there is apt to be increased weakness for a time in such cases, though even in these the exhilarating effect which always attends the treatment will follow in about an hour The extremities become warm and there is a sense of greater strength

Distinct effects upon the liver and kidneys can be traced to the treatment in many cases, the bowels become regular and the volume of urine greater It is also probable, though not yet demonstrated with precision, that these bulky currents produce functional stimulation of all the nerve centers and organs of the abdomen

1636 Walnut Street

ELECTRICITY IN THE TREATMENT OF EXOPHTHALMIC GOITRE

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

Much has been written on Basedow's disease or Graves, as exophthalmic goitre is often called Notwithstanding the large amount of literature on the subject since 1835, its etiology and pathology is not definitely understood or settled Most authors believe that it is a disease of the sympathetic system, having its origin in the cervical branch Treatment therefore has been more empirical and unsatisfactory The conclusion is, that exophthalmic goitre ends generally in death, usually caused by complications, of which a general nervous exhaustion and marasmus are prominent Recovery, however, may occur, even without treatment

While we have on record, reports of cures, the treatment by therapeutic means has not been satisfactory It is conceded that some remedies, like iron and digitalis, have allayed symptoms, but they scarcely cured the disease The ground of therapeutics is so well covered in reports that this paper will not touch on it and will only consider the treatment by electricity, which has promised to do more than medicines Successes have been reported by different authors who have given applications in different ways, but most agree that galvanism is the proper selection to be used in the disease under consideration

Galvanization has been used by v Dusch, who, in one case, after many séances succeeded in lowering the pulse from 130 to 70, and reduced somewhat the exophthalmus

Eulenburg galvanized the cervical sympathicus with similar results in 1867, using the negative pole He also used galvano-puncture without any appreciable result

M Meyer[1] reported four cases and Chvostek, who is a pioneer in the observation of this disease, has given much labor, and reports thirteen cases with galvanism in the same manner These observers report improvements in all cases in which they used galvanism, but do not pronounce decided cures

A D Rockwell[3] has treated cases in a similar manner with galvanism to the sympathicus He applied the negative pole over the cilio spinal center above the seventh cervical vertebra, and the positive in the auriculo maxillary fossa, gradually drawing the positive along the inner border of the sterno cleido mastoid to its lower extremity The second step consists of removing the positive pole to the position occupied by the negative, and placing the latter over the solar plexus, using for a minute a greatly increased strength of current

Galvanization of the sympathicus has also been practiced by Neftel

Eichorst uses the negative pole high up in the neck and the positive pole between the scapulæ, a current of five to ten cells for two minutes Then he applies the positive pole upon the cervical spine, the negative over the sympathetic and pneumogastric upon each side for two minutes, from auriculo maxillary fossa down the inner edge of the sterno cleidomastoid to the clavicle

As the affection probably begins in the medulla, currents have been passed through the back of the head above the spine Transverse currents have been passed through the goitre Several friends tell me they have reduced the size of the goitre by placing both poles near the thyroid, but it is evident they ignored other symptoms of the disease

Erb has tried very mild currents to the eyes with an uncertainty of benefit

Ziemssen recommends strong galvanic currents, and at the same time contradicts his own advice by urging caution in their use

Hunter McGuire uses the following galvanic application Positive cup-shaped electrode containing iodin on cotton over the gland, and the negative pole on the back of the neck

Frank D Boyd,[4] of San Antonio, Texas, reports improvement of one case in which he used very judicious treatment of therapeutics and daily galvanic application, but does not state how the galvanism was applied

There are reports from Vizioli[5] in 1878

Needles in goitre by electro-puncture have been used by Duncan,[6] of Edinburgh, and others with unsatisfactory results It seems that all surgical applications of electricity as galvano-cautery, electrolysis, cataphoresis, as well as electro-puncture, have given no beneficial or curative results Even the cataphoresis of Adamkiewicz, an electric anesthetic by diffusion, has given slight and very temporary relief of neuralgia

[4] Frank D Boyd Report of a case of exophthalmic goitre, Medical Record N Y March 30 1895

[5] Vizioli Elettoterapia practica Morgagni Germajo, p 69, 1878

From these reports it seems that all operators gave particular attention to the sympathetic nerves, but differed in the selection of the poles to certain regions and the way of application Some placed the positive pole to a region where others used the negative pole Some applied the galvanism with the apparent intention to allay only one symptom of the disease, while there are several symptoms to be looked after

The writer has treated within the last two years three cases of Basedow's disease with apparent good results, which can be called *cured* All three patients were females

The first case was a very aggravated one, who was ten years under electric treatment by one of the best authorities and practitioners in electricity During those years, in which the life of the patient was despaired of, slow progress was made under very careful and judicious treatment After the treatment had been suspended during a sojourn in the country, symptoms grew worse, and then in the fall of 1893 the patient came under the writer's care It needed one year's treatment before the patient declared herself well, and she has remained so up to date

A detailed history of this case is annexed here, from notes and observations by the writer's assistant, as follows

Case 1—W C, age 40, single She had been under treatment for nearly ten years with an authority in electricity and nervous diseases During that time she improved considerably, but was not cured An interruption of treatment was due to a sojourn in the mountains, during which time a relapse took place In November, 1893, she came under Dr Newman's care She then had all the symptoms of exophthalmic goitre, was very anemic, nervous system was unstrung, a great uneasiness a general nervous prostration, insomnia, sometimes nausea, anxiety, bowels disordered, with dyspeptic symptoms and all symptoms of neurasthenia The heart action was irregular, pulse varying between 120 to 150, temperature 100 Emaciation prevailed with scarcely any appetite The thyroid gland was enlarged—the circumference of the neck being thirteen and one sixteenth inches The eyes protruded very much, which gave the expression of anxiety to her face The case was very aggravated, so that her relations were alarmed about her life Her family history is good, but her father had heart trouble and her mother, who is still alive, has always had symptoms of dyspepsia

The treatment consisted of galvanism in various ways, three or four times a week In order to cause an absorption of the new tissue formed behind the eyeball, a medical electrolysis was used For the negative pole, a solution of chlorid of sodium was applied directly to the eyes, while the positive sponge electrode was held in the hand Only a very weak current was borne and the electrolysis was caused by the solution—like an eye-bath through which the negative pole acted—as an absorbent To the enlarged thyroid gland the negative pole was also applied in the form of a sponge pad, and in this the result expected was the diminishing of the size of the goitre by the chemic action of electrolysis The application to the nervous system, in which the sympathetic was included, was varied according to indications and the solar plexus received its share of attention One of the applications consisted of a helmet to the head, while the other pole was placed over the solar plexus This helmet was made of strips of German silver fastened to a circle, which corresponded to the circumference of the head To have an even action to the head the hair was wet with water, and a wet felt cap placed between the head and the helmet. The result of this treatment was satisfactory in every respect and all symptoms of the disease improved

May 1, 1894 Improvement in every respect Patient felt more rested, the unpleasant nervous excitement was calmed, and sleep procured Heart had a more steady action, pulse was reduced and the measurement around the neck was twelve and seven-sixteenths inches in circumference, five-eighths of an inch reduction Patient left in July, 1894, for a sojourn in the mountains, which interrupted the treatment, *pro tem* Sept 6, 1894 Slight relapse has occurred while being without treatment The thyroid gland has increased, and the measurement is twelve and five eighths inches around the neck September 20 Treatment in the same manner as before, with galvanism, has made rapid improvement Heart is more regular, pulse is reduced, eyes still prominent October 2 Thyroid gland is reduced so that the circumference of the neck measured twelve and one-half inches November 30 Thyroid still lessened—measurement twelve and seven sixteenths inches Treatment continued, no medicine given, only galvanic applications March 22, 1895 Neck's circumference normal size—twelve and three-eighths inches—the patient when in perfect health wears a twelve and one-half inch collar The eyes have resumed a natural look, without having any protuberance Heart's action is normal, pulse 76, temperature 98 5, all nervous symptoms subsided, good natural sleep procured Patient considers herself well, takes part in all the pleasures of life and enjoys all in an active way

Case 2—Had many symptoms like the first, but was not as aggravated The treatment was similar and has been pursued for nine months The patient, a female, 30 years old, has improved so much that a cure may be pronounced, but is still under observation with galvanic applications at irregular intervals

Case 3—The third patient was a young lady who sang a principal part in an opera company A question arises here if heredity has an influence, as her mother died of Basedow's disease This patient had an exophthalmic goitre which was correctly diagnosticated, and different physicians treated her with medicines for over two years, during which time she grew gradually worse, until at last, at a performance after reëntering the wings, she fell prostrated and unconscious, ending her operatic career for a time The patient came under the writer's treatment in December, 1894 The electrical treatment was carefully but vigorously pursued, on an average, five séances per week were held In less than four months this very aggravated case was entirely cured All symptoms have disappeared, the constitution improved, weight increased, and features restored Patient considers herself well and is ready to enter another opera company. (Since the above has been written, patient has appeared on the stage, and feels very well)

In this case were complications of severe oophoritis and endocervicitis There was hemorrhage from the uterine cavity which increased on the slightest touch, and also a profuse mucous discharge The region of the ovary, in fact, the whole hypogastrium was painful, and the sensitiveness was increased on any pressure These uterine troubles have been treated locally at intervals The only therapeutic agent given this patient has been peptonate of iron to improve the quality of her blood on account of the anemic state, which was very marked The iron was given when the nervous symptoms were improved, and then it acted well

The electric treatment of this case consisted of galvanism, given in different ways and places The galvanic treatment was assisted by the spray of the static machine The spray was given twice a week very cautiously over the spine, head and over the sensitive parts of the ovaries with very good effect

The history of this case has been written up by the patient herself, in which is embodied notes about her mother, who died of Basedow's disease The interest is in the question of heredity The diagnosis in both cases of mother and daughter had been made by several eminent physicians with an unfavorable prognosis These notes are here annexed

---

History of the Third Case The patient, Z R , writes as follows

New York, April 6, 1895

At the age of 16 I had just returned from Europe, it being a pleasure trip only After being home but a short time I was taken seriously ill The palpitation of my heart troubled me dreadfully, and occasionally a spasmodic pain of the heart which was severe while it lasted My feet began to swell and I was so prostrated, physically that it was impossible to go the shortest distance without great exertion and fatigue Dr Loomis, the great authority on lung and heart diseases pronounced me incurable and warned my mother not to allow me to go anywhere without an escort, as I was liable to drop dead at any moment My mother shortly afterward was advised to put me under the care of Dr Louis Conrad He said I had a defect in the heart which was incurable, but if I took care of myself and led a quiet life that it would not bother me He also informed my mother that I was subject to a disease called "chlorosis," or 'poverty of the blood " Nevertheless, under his treatment I survived, not being very strong at any time—naturally delicate About three years later my mother, having enjoyed good health up to the date making her forty eighth year, began to complain , being of a bright, strong temperament and was subject to very severe, nervous headaches

I wish to say that she was a great business woman, having as many as 300 hands under her employ at one time, which made a great deal of brain work for her but at the time of which I speak, from that period, she seemed to fail gradually She grew more excitable, easily fatigued, excessively nervous, gave way to temper at the slightest provocation, which would terminate in a severe nervous headache, and the only cure was perfect quiet in her room in complete darkness A year later, she complained of increased fatigue, but I presume the Basedow's disease was gaining more hold on her system Her heart beat so tumultuously that she felt the pulsation in her throat, but her neck did not increase very much in circumference The inflammation of the eyelids and bulging of the eyeballs—this last being made more prominent by a staring expression Her knees gave way, but being of a determined disposition she would not go to bed

Shortly afterward, I went away on business My mother became annoyed at a servant, gave way to a fit of temper, and the excitement was too much for her She fainted, and from that day to the day of her death was confined to her bed As she had previously used up her strength worrying about domestic affairs, business was a thing of the past

From that time her heart beat faster and more irregular , marked pulsation was felt in the throat, ends of fingers, in fact, all over her body Under the optician's examination there was found a pulsation in the eye She had a hacking cough, at times violent, especially after eating, which would make it almost impossible for her to keep any food on her stomach, but that did not surprise me as each doctor would give her a new dose of medicine, and between the various ones and the medicine that would be given after each consultation I do not wonder at her digestion being ruined

Mother suffered all her life with constipation, the treatment of which she neglected The doctors gave her some medicine which made her bowels so loose that it made her very weak Three weeks before she died I had to take her to a hospital, one of the best in the city The doctors there gave her champagne, and it made her delirious After one of the delirious attacks she was put to bed by four doctors They told me she asked after me, required my presence, turned over and died She was 50 years old

I was sleeping, and as I was exhausted with the care and worry about her , I was not called until too late She died of exhaustion and with a pulse of 180 I have always had a doubt in my mind as to her death being easy—I suppose the doctors wanted to spare my feelings, but the truth would have been preferable I nursed and attended her through her entire sickness—the serious period being about seven months During the above period she lost flesh rapidly and was very much emaciated

A few months after my mother's death I was married My married life was a failure from a domestic and physical standpoint My husband abused me, which run my health down dreadfully, and combined with the shock of my mother's death, which I will never survive, I became a bunch of nerves

I have been doctoring for two and a half years and no relief In June I shall have been married three years, and will be 25 years old the 30th of next October

The doctors have not helped me one particle All they did was to fill me with opiates and chloral which almost killed me—in fact, I was in a state of complete collapse Four months ago I called in Dr Newman—having all the symptoms of Basedow's disease previously mentioned nervousness, sleeplessness melancholia, loss of appetite, irregular action of the heart, very excitable irritable temper, general fatigue at the slightest exercise, a feeling of numbness in the limbs swollen feet and pulling out of the flesh in which the finger could make an impresion After four months of galvanic electricity, I feel better than I have for years and consider myself well enough to discontinue treatment Occasional application from the static machine often relieved me of a nervous headache , in fact, relieved a pain in the spinal column which was for a period continuous and very painful

REPORTS OF CASES

On record are reports of cures by medicines, electricity, both combined, and even spontaneous cures These results, however, are exceptions, and the rule in the treatment of exophthalmic goitre is that they are failures, often ending in death It is also conceded by most authors that electricity, in this disease, gives better results than medicines This, however, does not prove that electricity in any form, and even given by specialists, always cures

There are failures and unsatisfactory results reported The writer has made diligent inquiries among reliable specialists in electricity and been told of cures, benefits, as also of indifferent and unsatisfactory results and even failures Such results must be expected, as the *modus operandi* of electricity has been conducted differently by the operators, and it seems even on entirely opposite plans

TREATMENT

Electrical specialists in the treatment of exophthalmic goitre have mostly given galvanism to the sympathetic, and in this they all agree They differ, however, in the selection of the poles, the direction of the current, the size of the electrodes, the duration of the séance and the intervals

It seems, further, a mistake to treat solely the sympathetic system and to overlook other important points of this disease Most European authorities give the electric applications too short, being from one to two minutes' duration, while in America such séances are prolonged to about twenty minutes, which tires the patient and gives too great stimulation The question arises, if it would not give better results to arrange the electric applications more rationally to symptoms and complications, as with our present knowledge neither etiology nor pathology of this disease is settled

PROMINENT SYMPTOMS

Beside complications and natural consequences, exophthalmic goitre has three prominent symptoms to which the treatment should be directed These are

(*a*) Irregular heart action with all kinds of nervous symptoms

(*b*) Enlargement of the thyroid gland

(*c*) Protrusion of the eyeballs

Complications are anemia, emaciation, insomnia, uterine diseases, irritability, edema, fainting spells, etc

The Indications for Treatment are (*a*), to reduce the pulse, regulate the heart action, produce rest and sleep and allay the nervous symptoms Beside the sympathetic system it is necessary to regulate and treat the pneumogastric and vagus , (*b*), to diminish the size of the thyroid gland, (*c*), to remove the plastic new formations behind the eyeballs

The Treatment, therefore, would be

1 Galvanism to the sympathicus, vagus and pneumogastric, in such form as to reduce the pulse and stimulate the heart's action In other diseases, galvanism quiets to such a degree that patients fall asleep while the application is given

The Strength of the Current must be regulated according to the toleration of the patient in every case The operator must exercise great care in slowly increasing the electro motive force of the current, till the exact amperage is found, and every step of increase and decrease must be made with care and without any accidental shake or jerks of the current The exact measure in milliamperes can not be advised and depends entirely on the sensation in each individual case Some patients may be so irritable that even 2 milliamperes may be too much, while others can endure 20 or even 30 It is also essential to regulate the strength of the current in the same patient according to the region to be galvanized, to the size of the electrodes and the resistance between the two poles

The *Static Electricity* will assist to regulate the vascular circulation, allay nervous irritation, creating a sedative to the heart and a more refreshing sleep

2 The thyroid gland will be reduced with almost a certainty by the negative pole of the galvanic battery Some report good results by applying both poles near the gland, one on each side While this may have result the method is harsh and not rational Surgical means have not been successful

3 The protrusion of the eyeballs can only be cured by diminishing the new formations of tissues, grown behind the eyeballs, by which the eyes have been pushed forward This can be done by the use of the negative pole to the eyes, which acts like an electrolysis absorbing the foreign tissues The complications have to be treated according to indications

The static electricity is here recommended only as an assistant and must be given with care Sparks are contra-indicated, as they are too severe and will create often more nervousness and even pain Breeze or spray will act well, allaying pain and regulating the circulation

There Should be Avoided Too strong currents, too long séances, which tire the patient and over stimulate internal electrolysis, and surgical electricity The faradic current has been used and recommended, given with certain precautions, but it seems it is contra-indicated, as a severe measure, which overstimulates and disturbs more the diseased nerves

With regard to general rules, avoid also excitement, over-exertion, stimulants, strong tea and coffee It is evident that the treatment, and especially the application of the electricity, must be intrusted to an expert, and that the family battery for self-use (or abuse) is entirely out of the question

ELECTRICITY IN THE TREATMENT OF OCULAR NEURALGIAS

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md May 7-10 1895

BY HORACE M STARKEY, M D
CHICAGO

It is with much diffidence that the writer responds to the invitation of your chairman to present a paper to this Section, for if there is any class of men for whom he has the most profound respect and before whom he is inclined to stand in silent awe it is those who are solving the complex problems presented in the study of the construction, functions and diseases of the nervous system He is, however, the more willing to present a very simple and practical fragment to this symposium, because he is not aware that much has been written on this particular phase of the subject, and because he finds no reference to it in the very able paper on "Electro-Therapeutics of Diseases of the Eye," read before the last meeting of the American Electro-Therapeutic Association, by Dr L A W Alleman, of Brooklyn

The intimate relation between eye strain and disease of the nervous system is so well known as not to require mention Many persons with weak and unstable nervous system are kept for years in a condition of invalidism, and suffering because of a constant excess of expenditure of nervous energy in some particular direction Probably the most frequent source of such excess of expenditure is to be found in the eye and its appendages It is the duty of the ophthalmologist to seek out and endeavor to correct these various sources of irritation, whether due to faulty shape of the eyeball, to irregular action of the eye muscles, to defective nerve impulses or to inflammatory diseases Many patients are found in whom an error of refraction, or difficulty in maintaining the eyes in position for single binocular vision, or weakness of the external and internal muscles of the eye, or all these combined, have been for years the cause and source of headaches and pains in and about the eyes Most of these cases are relieved with more or less promptness by removing the cause A certain number of them, however, are not so relieved The long-continued over-stimulation and irritation of the nerves seem to have induced a hypersensitive condition and a habit, as it were, so that, after the most careful correction of refraction and of muscular balance the neuralgia continues

Many of these persons just described, whose condition is truly pitiable, appear to be relieved by the systematic and careful use of electricity But while many are so relieved, some unfortunately are not, and continue to have almost constant pain, more severe on use of the eyes, notwithstanding all that we can do for them As we are more careful and exact in diagnosis, however, the number of such unrelieved cases becomes smaller

There are two classes of the patients mentioned above, to whom electricity may be advantageously applied 1, those with weak extrinsic muscles who may receive the primary faradic current for its direct effect upon those muscles, and 2, those in whom neuralgia persists after removal of the exciting cause, and who should receive the galvanic or the secondary faradic current

A brief description of the method of application may be serviceable First, as to time The time required for a treatment is from two to eight minutes, with a probable average of four or five minutes, depending upon individual peculiarities We probably all begin any electrical treatment with a minimum of time and current, and then increase both as we find indications for so doing The indifferent electrode of absorbent cotton, three inches in diameter, is held by the patient to the mastoid, and neck just below the mastoid on one side the first half of the application, and on the other side the last half In applying the faradic current a double eye electrode may be used over the eyes, but the operator's hand makes altogether the best electrode, because the fingers can be used to single out the different muscles and convey the current more directly to them The current employed should be mild, so as to produce a sense of tingling with little or no actual pain Unfortunately we have as yet no practical means of measuring the faradic current For the persistent neuralgias the secondary faradic current should, from theoretical grounds, be most useful, but practically, the weakest application of this current about the eyelids is often so painful that it will not be tolerated The sinusoidal current would probably be better borne Very decided and immediate relief is frequently obtained from the galvanic current with the anode as the active pole In this application, the time and the position of the indifferent electrode are as stated above, while the active positive electrode, which is preferably double, is applied by a gentle massage motion to the lids, cheeks, brows and temples The amount of current required is but from 2 to 5 milliampères, though in some cases even this very small current is too great for comfortable use The current is usually very soothing and grateful, and patients frequently express surprise at the rapidity with which the pain is relieved and at the calm content and drowsiness that steals over them This effect is very likely due in part to the action of the current on the cervical sympathetic The duration of relief from pain is quite variable, it may at first be but a few minutes and it may continue for several hours Usually, where benefit is to be secured, the time of relief increases as the treatment progresses, so that in a case where the first application gave relief for one hour, the third may give relief for two hours, and so on, until the pain is absent from one day to another, when the time between treatments may be lengthened and ultimately the pain is entirely relieved A few cases were briefly summarized, but the limit of papers in this symposium will not permit their introduction

NOTE —A time limit of four minutes was placed upon these papers

DISCUSSION ON PAPERS READ BY DRS WATSON, MASSEY, NEWMAN, AND STARKEY

DR WILLIAM J HERDMAN, of Ann Arbor, Mich —I was sorry that Dr Watson did not more specifically state the nature of the esophageal strictures with which he had been dealing His experience has certainly been very satisfactory The procedure he adopted is that which I have generally found, from examining the literature of the subject, to be most likely to result satisfactorily, that is, the gradual dilatation of the stricture with the assistance of the negative electrolytic action What I believe to be the fact as demonstrated by laboratory tests on living tissues with negative electrolysis, is that by a cataphoresis we have drawn to the spot, when the negative pole comes in contact with the issue, an increased fluidity Not only is the fluidity increased, but at the same time we have an alkalinity produced by negative electrolysis You have there the conditions for gradual disintegration of fibrous tissue Where you have a purely spasmodic stricture, as possibly was the case in some of the instances mentioned this morning, it is overcome by action through the nervous system By passing the current from above downward and producing the natural order of esophageal contraction, you habituate that part of the esophagus to pursue the normal peristaltic action Peristalsis in the esophagus is reversed in a good many of these cases and much of the difficulty arises from some part contracting below while the upper part is dilating, in other words an irregular distribution of nerve impulse to the muscular tissue occurs, and you can gradually overcome that by the electric current It matters not in that case whether it is the positive or negative pole But when you have fibrous tissue to deal with, you have a pathologic barrier which is not spasmodic, but genuine and real to overcome, and there electrolytic action by means of a negative pole is essential To my mind it is the only rational procedure we have A surgical procedure leaves only another cicatricial band By the cataphoric action of the electricity you increase the fluidity of the part and this fluidity distends the fibers in the cicatrix, then, by means of the alkalies which are drawn there by electrolytic action the tissues are dissolved You are practically using an alkalin caustic This is the same process that Dr Newman has adopted for the removal of cicatricial bands in the urethra It will serve the same purpose for the ophthalmologist who attempts to dilate a stricture of the nasal duct, and it will dissolve cicatricial bands in the neck of the uterus I have used this method over and over again in esophageal stricture and frequently in urethral stricture It is a physical process which can be demonstrated at any time upon living tissue in the lower animals

There is one thing that was said by the author of that paper which causes me to doubt the efficacy of his method He makes use of aluminum electrodes Now aluminum is the only metal which is dissolved by the alkalies or by use as the negative pole, and his electrode is not only dissolved away in this manner, but there is a question as to whether he does not get an irritating effect from the sodium aluminate and the potassium aluminate which is formed at the point That these substances are formed at the negative electrode during electrolytic action when aluminum is the material employed, I am quite satisfied from tests I have had made for me some sodium and potassium aluminate in the pure state with the view of testing its action on the tissues It is very acrid to the taste, but I have not as yet investigated its action on living tissue to determine to what extent it is irritating There is no question that certain substances are carried into the body by means of the negative electrode There are those who hold that cataphoresis is carried on solely at the positive pole, but there is a cathodal diffusion as well It is just as well to make use of steel electrodes as those of aluminum Dr Newman has taken up the interesting and perplexing subject of exophthalmic goitre This one fact has come out from all recent methods of treatment advised for exophthalmic goitre, that galvanism is an indispensable element in the treatment I have had occasion to look over the literature of exophthalmic goitre during the past eight or ten years pretty thoroughly, and during that period I do not think there is an author speaking of it or a writer writing concerning it, who does not put galvanism in a prominent place in the method of treatment, but it is amusing to see what a variety of methods they have employed for applying galvanism Some make use of the negative pole over the thyroid, some the positive Some treat the cervical sympathetic, putting one electrode underneath the ear and the other on the sternum, with a view to bring as much of the cervical sympathetic under the influence of the current as possible Others adopt a transverse method There is very little that can be inferred from this as to what value or what particular effect it is that galvanism produces in this treatment Every one has this idea as to the pathology of exophthalmic goitre and I have had mine for a good many years The notion of the pathology differs almost as much as the persons speaking of it, each one seeming to have a different conception This only indicates to us how little we know about it as yet I have now had twenty-three cases of exophthalmic goitre, every one of these, although some of them seemed to be desperate at the outstart, are well to-day. The worst case I can recollect is that of a woman in Kansas who was bedridden and very extensively edematous. Her respirations were 40 to 45 per second and her pulse rate was 140. She was unable to bear a teaspoonful of any nourishment on her stomach. That woman is perfectly well. Others have not been so serious in their conditions, but some of them were certainly very low. Galvanism was in all of these a very prominent part of the treatment. I would not regard galvanism of itself as the only method to be employed; in fact, I regard it as absolutely essential to make use of accessory measures, such as cardiac stimulants and measures for promoting nutrition. My experience may not be different from others, because I think other measures of treatment of this malady are more successful than those of a few decades ago. I am presumptuous enough to regard this disease as always curable.

As to static electricity in exophthalmic goitre, I think its effects are good. It acts as a vasomotor stimulant and assists in that way. I was extremely interested in the paper read by Dr. Kellogg upon the physiologic effects of the sinusoidal current. In the treatment of that subject, Dr. Kellogg has made considerable progress toward accuracy in the use of electricity. D'Arsonville, some few years ago, made the statement that the physiologic action of electricity depended upon the "curve of excitation" produced by the instrument employed. We have in static electricity an alternating current of extreme rapidity. Billions of alternations take place in the course of a second during the passage of the spark. The current, however, is very minute in quantity. The electro motive force of the current is enormous; it is sometimes millions of volts. The amount of electromotive force required to cross six or seven inches of dry air would need to be enormous. The effect produced physiologically by such an electro-motive force, with a very small current, but a current which is rapidly alternating, must differ much from that of an induction coil which is alternating perhaps only two or three hundred times in a second, where the electro motive force does not exceed 30 volts and where the current as compared with the static machine is greatly in excess. The static machine may have only 1 of a milliampère of current, where the induction coil may have 10 milliampères or more. All forms of electric apparatus differ in the character of the curve which is produced. D'Arsonville called that the "characteristic of excitation," and the "characteristic of excitation" has its relationship to physiologic action. Dr. Kellogg brought out this fact in regard to the action of the sinusoidal current. This, he says, has extreme penetrating power, so that its action upon the muscular system is very decided; in other words, that it does not act upon the sensory nerves to any extent, but it does act markedly upon the muscular tissues, and for that reason serves a great variety of purposes that no other current serves so well. I think the reason for this lies in its peculiar "characteristic of excitation." In other words, that the sensory nerve terminals do not respond to an alternation of that character while muscular tissue does. It is not probably due so much to the penetrating power, as to the character of response which a sensory nerve is capable of making. He finds, for instance, that this current will produce no sensation at the temple, whereas there will be sensations of light excited in the optic nerve or in the retina. Now we know there is a great deal of difference in sensitiveness between the retina and the skin, and the reason it excites the retina when it does not in any way cause sensation on the skin is not, in my opinion, due to the penetrating powers but to the fact that the nerve distribution in the skin differs in the manner in which it responds to external excitations from that which we find in the retina. The retina is capable of responding to light, which, as we all know, has billions of vibrations per second. I believe that in our investigations concerning electric action we will eventually have for one purpose one form of current, and for another purpose a different form, according as the tissues respond to one or the other. We all know that we can get such a rapid vibration and high voltage of current that it can be passed through the system without our knowing anything about it. In the atmosphere of Tesla's laboratory you have vibrations passing through you and at such voltage which, if slower and lower, would kill instantly, but being so rapid they have no appreciable influence on the economy. In our therapeutic applications of these various forms of electricity, we must eventually know what is the "characteristic of excitation" of every machine we make use of, and in that way we will get a scientific application of electricity that will have its physiologic and therapeutic counterpart, and I think toward that result we are rapidly tending.

Dr. G. Betton Massey, of Philadelphia—One point in Dr. Herdman's remarks I might take exception to, in regard to the excitation of the sense of vision by the sinusoidal current. Heretofore the sense of vision has been excited only by the galvanic current and not by the faradic. It has occurred to me that the reason why the sinusoidal current causes a response by the retina is on account of its larger amperage. I can not say what the amperage of this machine is; it is somewhat difficult to find out as it is an alternating current. It is well known that it is not a direct excitation that necessarily causes the sense of light, but a reflex one. That was a matter under considerable discussion some years ago, and I myself, in 1885, contributed to the American Neurological Association the report of a case of anesthesia in which the absence of the galvanic test was marked in an area of anesthesia about the size of a dollar over one eye; no matter how strong the galvanic current we could localize in that point, although within an inch and a half of the retina itself. Yet, anywhere outside of that area, galvanic currents with interruptions would produce both taste and sight. One of the uses of the sinusoidal current will be the power of giving rapid alternations of practically slight galvanic currents of such regularity and gradation as to cause muscular contraction without pain, since the variation is not quite acute enough or irregular enough to cause sensation.

Dr. Hugh T. Patrick, of Chicago—I would like to differ with Dr. Herdman when he says the galvanic current is an indispensable means of treatment in Graves' disease. I would like to make the point that in many different varieties of treatment of this disease, it improves and pursues a favorable course, although not generally to complete recovery. I happen to have seen in the last three or four years, about sixty cases of Graves' disease. These were seen under the care of various observers and were consequently under various methods of treatment; some of them purely hydrotherapeutic, some purely faradic, some purely galvanic, some purely dietetic, some purely rest treatment, and so on. I do not think that among all these cases I saw one which was treated for a length of time, sufficient to judge of the treatment, that did not improve. The only thing which I saw in common in the treatment was repose, rest and general hygienic measures. Now I beg leave to offer the opinion that the rest treatment and general treatment alone may give exceedingly favorable results in the treatment of this affection, equal to any that have been produced by the galvanic current; and I do not think that our enthusiasm for electrical treatment should carry us so far as to say that galvanism is indispensable in the treatment of Graves' disease.

Dr. George J. Preston, of Baltimore—One little point concerning exophthalmic goitre, and that is the immense loss of electrical resistance. That was called to my attention some ten years ago by Vigarow, who was, I think, the first observer of the phenomenon, that in cases of this disease there was practically no electrical resistance. In the somewhat limited experience I have had in such cases, I have been able to confirm this, that the electrical resistance is practically *nil*. I have been quite at a loss for any satisfactory explanation of this point. I asked my friend, William J. Morton of New York, an authority on such matters, and he said that he thought it was due largely to excessive moisture of the skin. My own experience would not bear that out. There is evidently some special susceptibility to the negative current in these cases. It is a noteworthy fact that when the thyroid has been removed, surgically, the same loss of electrical resistance results, and this brings out a curious similarity between the removal of the thyroid surgically and exophthalmic goitre, which seems to bear some remote relation to the thyroid gland.

Dr. G. B. Massey—Can the Doctor tell us what the resistance was in these cases? It is startling to hear that there is no resistance; even a copper wire has resistance.

Dr. Preston—I did not expect to be taken literally when I said that the resistance was lost. I frequently measured the resistance and found it down as low as about 500 ohms and in one case as low as 300 ohms, using an electrode about 4 cm in diameter. I used an electro-motive force of perhaps 20 to 30 milliampères. I used an ordinary Wait & Bartlett machine. Normal cases under like conditions would give a resistance of about 2,000 ohms.

Dr. Chas. G. Hill, of Baltimore—Speaking generally of electro therapy, I wish to say that we have much to learn in that line, notwithstanding the rapid advancement recently made, as evidenced by the excellent scientific papers read before this Section. I recall many cases of the application of electricity for the reduction of the thyroid in exophthalmic goitre, and some cases would melt away like magic while in others there was practically no effect I have applied electricity in other lines, in surgery for instance, and sometimes with very good results I recall one case of a small fibroid beneath the skin which would have caused no inconvenience except for the pressure upon it of the dress sleeve The patient, a nervous woman, objected to the knife I applied the *constant current*, not expecting much from it, and was very much surprised in two or three applications to find that the tumor disappeared entirely There is another point which was not brought out to day, and that is one of the peculiar effects of the electrical current in the production of ozone in the tissues We never apply an electrical current, constant or faradic, that we do not develop in the tissues a certain amount of ozone, and probably it is through this agent that we often get the effects which are realized by the application of the current

DR THEODORE DILLER of Pittsburg—Regarding the lessened resistance in Graves' disease, it seems to me that the explanation offered is a rather reasonable one The increased moisture of the skin, together with the capillary dilatation would seem to me to be sufficient to account for the phenomenon This opens up another thought, which is, that this lessened resistance being so constantly present in Graves' disease may be useful as a diagnostic feature For instance, I have on two occasions seen cases of tachycardia Very often this increased heart's action is the first symptom of Graves' disease, and I quite agree with Dr Herdman that it is the most constant symptom In cases of tachycardia, therefore, it would be well to measure the resistance, and it might lead to important indications I would like also to record my experience with the constant current in Graves' disease It has been exceptionally unsatisfactory I have never seen it do much good Only recently, after a six weeks' course of treatment, the patient coming to my office, there was no good result whatever The patient was then put upon some medication, and three or four weeks later was sent to a hospital and remained in bed for six weeks without medicine of any kind Under the rest treatment there was marked improvement I believe that of all forms of treatment known to me that rest is the most efficacious I would like to ask these gentlemen who have recorded observations, in what condition the patients were who were receiving galvanism whether they were in bed or going about

DR HUGH T PATRICK—I am sorry that my personal experience can not contribute to our knowledge of the decrease in resistance to the electrical current In most of the cases in which it was tested, there was undoubted diminution The explanations which are thus far produced hold good for some but not for all of the cases Regarding the conditions of the patients I saw treated, most of them were able to be about, but some of them were in bed The worst case I saw was that of a woman whom I observed almost constantly during the better part of a year She was better and worse, better and worse under galvanic treatment, and finally she was decidedly worse. She was then put into a hospital and was there so bad that she could not turn over in bed She had hallucinations, her chest expansion was about three-fourths of an inch and her pulse at times could not be felt at the wrist We all expected her death She went home however, and within six weeks after leaving the hospital had gained almost fifty pounds in weight under practically no treatment at all but rest at home, whereas before she had grown worse at home under galvanic treatment

---

OBSERVATIONS ON SOME CHARACTERISTICS AND RELATIONS OF THE DYNAMIC AND STATIC FORMS OF ELECTRICITY

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7 10 1895

BY A D. ROCKWELL, M D

NEW YORK

The more thoroughly one studies electro therapeutics in all its relations, medical and surgical, the clearer it becomes that the real scientific basis for the use of electricity in medicine and surgery is found in electro physics more than in electro-physiology, and therefore in studying the therapeutic characteristics of electricity, and the relations of its various forms to each other, we can not be too well grounded in the laws of electro physics

One of the most perplexing questions to the tyro in electro therapeutics relates to the differential indications for its use, but if one is well equipped with a knowledge of physics, with a well directed clinical experience, the various special problems that arise in practice, whether of a theoretical or a practical character, very quickly resolve themselves Often in discussing the subject with members of the profession more or less interested in electro therapeutics, I have noticed a manifest tendency to use one form to the exclusion of the others, and an especial tendency to discard the faradic current, in favor either of the galvanic or static electricity

The contention is, on the one hand, that its quantity is so small as compared with the current direct from the cells, that to mechanical influences alone must be attributed whatever beneficial effects follow its use, and, on the other, that its nutritional effects are inferior to the static form of electricity because of the tremendous electro-motive force or voltage of the latter Broadly speaking, seeing that static electricity is all voltage with little amperage or quantity, and that the galvanic current is all amperage with little voltage—while the faradic current occupies a position between the two—there are in these conclusions a manifest contradiction The truth is that each has, in some respects, a special field of its own, and no one of the manifestations of electricity can be dispensed with, if one expects to get all the results that it is capable of giving In regard to the faradic current therefore, it has been urged that other mechanical methods—massage, tapping, and contrivances for producing rapid vibratory movements are equally serviceable Those, however, who hold these views have but a very incorrect appreciation of the true action of the faradic current, and have certainly fallen far short of completeness in their practical experience with it

Many years ago, when I first began to use electricity in practice, my efforts were of necessity confined to the faradic current Galvanic apparatus was not obtainable, and whenever it was desired to use the galvanic current one had to resort to the inconvenient and ill-smelling voltaic pile This necessity was not altogether without its advantages, however, since it, for the time being, relieved me of the somewhat perplexing problem of current differentiation and enabled me to give undivided attention to the faradic current One of the most common observations as to the effects of a thorough general application was a relief of muscular tire after prolonged activity, and an increase in the flexibility of limbs that had become sore and stiff after the rest following excessive and unaccustomed muscular exertion One does not have to search far for a rational explanation of these well-known effects of electricity, although at the time a general want of appreciation of the physical characteristics of the current gave to most of the explanations offered a fanciful rather than a scientific and practical basis

Mechanical influences were undoubtedly predominant, not, however, as manifested by vigorous muscular contraction, but through molecular agitation, sufficient to give passive exercise to both the superficial and the deeper lying tissue In these cases we get, associated with cell exhaustion, a condition of circulatory sluggishness with a deposit of the toxic products of metabolism, conditions which are well adapted to appreciate the corrective and exhilarating effects of molecular agitation

It is on the selfsame principle that the faradic current is now applied with such admirable results in chronic congestions and indurations of the uterus and affords such instantaneous relief in some of the simple non-mechanical varieties of dysmenorrhea The blood-flow in the over-congested organ is accelerated A sort of circulatory drainage is established and a healthy local action more quickly and effectually brought about than by any known method If, therefore, we obtain from the faradic current effects that were simply mechanical and nothing more, we would still find it a very good thing to aid us in our therapeutic efforts We do not get from it, to be sure, any marked chemic or endosmotic or exosmotic effects, but we do get physiologic effects of the most pronounced character, and as the physiologic effects of electricity take place in living tissue alone, while all other effects are observed in the dead as well as in the living—in inorganic as well as organic substances—these physiologic effects are of chief concern to us as physicians in the consideration of the nutritional effects of electricity We find, then, that this current accelerates the circulation, influences the secretory and excretory processes of the body and hastens absorption To what extent these physiologic effects are of mechanical origin no one, I am sure, is yet quite prepared to say, but the results which follow this method of treatment render it reasonably certain that we get upon the nerve structure itself, together with medical effects, influences of an entirely different character

The claims made as to the advances in electro-therapeutics during the past few years are large perhaps too large, but yet in some directions—especially in the realm of gynecology—much has been accomplished Interstitial electrolysis, as suggested by Gautier, is a method of considerable interest, and although it may not fulfill the expectations of its author, yet some promising results have been reported and more may be hoped for By this method the chemic action of the positive pole is utilized, not only for its effects upon the tissue itself, but upon the metal electrodes, mainly copper or zinc, that are applied directly to, or inserted into, the diseased part In this way, new salts are formed and deposited in the tissues, oxychlorid of zinc when zinc, and oxychlorid of copper, when copper electrodes are used It is the cataphoric property of the current, however, which carries or forces these salts, the product of electrolytic action, through the surrounding tissues to a greater or less depth according to the strength of current and treatment The technique of this treatment can not be entered into here, further than to say that the positive pole is always the active pole and that the necessary current strength is from 20 to 40 milliampères The best results seem to have been obtained in diseases of the endometrium, although the method is applicable to various other diseases of the uterus and appendages

Another advance in the utilization of the galvanic current is by what may be termed the depolarizing method In 1892 I described the depolarizing electrode, with experimental observations, and in 1893 some suggestive clinical results following the use of the method in various forms of disease Briefly stated, the idea is to altogether eliminate either one or the other pole, according to the indications for treatment By using an electrode with resistance in ohms equal to or greater than the resistance offered by that portion of the body between the electrodes, the neutral point is thrown outside the body, which may at will be brought under the influence alone of either the negative or positive pole

It would not have occurred to me to consider the possibility of any special therapeutic effect being associated with this simple and well-known fact of electro-physics, had I not been led to make some experiments that revealed a number of exceedingly interesting and suggestive phenomena—and quite new so far as I can find out—in the realms of electro-physiologic experimentation

If two needles connected with either pole of a galvanic battery are thrust into a piece of raw beef and a current of sufficient strength allowed to pass for a few minutes, litmus paper applied at the point of entrance of the positive pole shows the regulation acid reaction and at the negative pole an alkalin reaction. If now we intercalate on the negative side a properly constructed electrode, having a resistance sufficient to throw the neutral point outside the body, a very different condition of things is seen At the positive pole the same strong acid reaction is obtained, but under the negative pole there is little if any observable reaction On testing the liquid, however, inside the electrode, the seat of the neutral point, the alkalin reaction is obtained, the same as at the point of contact on the body when the ordinary electrode was used

The most interesting experiments, however, were those made on the legs of a frog, which, as is well known, retain their irritability to stimuli for a long time after death If, after decapitation, the hind legs of a frog are subjected to the influence of either the positive or negative pole by the use of ordinary electrodes, the changes in irritability are imperceptible If, however, they are subjected to the influence of the positive pole alone, the action of the negative pole being eliminated in the usual manner, the muscles of the thigh will exhibit very decided diminished irritability If, on the other hand, the action of the positive pole is eliminated, and the limb is subjected to the action of the negative pole, we get the characteristic phenomenon of catalectrotonos or increased irritability, and the muscles readily respond to currents much weaker than when they are in their normal condition

These phenomena and various others are all readily verifiable, and for a more detailed account I refer to former articles [1]

Utilizing the suggestions offered by these interesting physiologic observations, I have not unfrequently found it possible to favorably modify and even permanently relieve various conditions that formerly were not relieved by the ordinary methods of application So far as the faradic current is concerned, the great utility of currents of high tension when applied through low resistance in the human body and especially by the bipolar method can not be overestimated As an analgesic in uterine and abdominal pain, when passed through the low resistance of the mucous membrane, these induced currents of tension are of the greatest value, but so far as outward applications of the faradic current are concerned, I doubt whether we have made much practical advancement either in the methods of application or in the efficiency of apparatus, and in saying this, I do not forget the alternating sinusoidal currents introduced into electro therapy by D Arsonval, the essential nature of which is that it has a uniform rise and fall of potential from zero to the maximum and back again in both directions For this current it is asserted that it possesses greater penetrating power than the ordinary faradic current, and that less pain attends the vigorous muscular contractions that it produces In comparing the effects of this and other modes of electrization, D' Arsonval says 1, that the continuous current does not show any immediate influence on nutrition, 2, Franklinization increases respiratory combustion, but in a less manner than sinusoidal currents, 3, ordinary faradization with a very feeble non sinusoidal alternating current can increase respiratory combustion without pain, but with a strong non-sinusoidal current produces a fatal electrical tetanus

---

[1] New York Medical Record, May 14, 1892 and May 6, 1893

My own experience, however, teaches me that, for most practical purposes, the old continuous coil with its 2,000 feet of wire and its perfect rheotome attachment, yields a current the essential character of which, as an aid to nutrition and for general tonic effect when applied externally, has not yet been surpassed It has always seemed to me that the most important thing in electricity in medicine, the fundamental idea upon which all its therapeutics is based, is its nutritional power It is this idea, which, in connection with Dr Beard, I enunciated many years ago, and upon which I have based almost everything I have said or written upon the subject since As to which of the various manifestations of electricity possesses the greatest efficiency in this direction, ideas will differ according to the extent and character of one's experience Static electricity is undoubtedly a most valuable addition to our armamentarium I could not afford to do without it No one who expects to meet the demands of all the varying idiosyncrasies of the nervous system can afford to be deficient in the completeness of his electrical outfit And yet the introduction and popularization of static electricity is responsible for a vast amount of unscientific and inefficient work in electro-therapy among those who confine their efforts to this form of electricity, with little knowledge of the subject in its entirety With a magnificent static apparatus in all its pyrotechnic glory, set in motion and readily controlled by an electric motor, the treatment of a patient becomes the simplest and easiest thing in the world, both for physician and patient, and I should be glad to assure myself that it is the most efficient method of securing the tonic and nutritional effects of electricity But after years of observation and comparative trial, I regret that I can not come to this conclusion I regret it, because it has the great advantage of ease and simplicity of application over the general use of the faradic and galvanic currents For other reasons, however, it is not to be regretted It would indeed be a misfortune if in order to obtain satisfactory nutritional effects from electricity, the costly static apparatus which few can possess was an absolute necessity Static electricity must ever be considered as an adjunct, merely, to the dynamic form of electricity, and this truth will always be taught by those who combine both an honest purpose and a thorough experimental knowledge of the subject

IMPURE MILK IN RELATION TO INFANTILE MORTALITY

Read before the Medical Society of the District of Columbia Nov 1 1895

BY GEORGE M KOBER M D

PROFESSOR OF HYGIENE, MEDICAL DEPARTMENT GEORGETOWN UNIVERSITY, WASHINGTON, D C

Last winter I had the pleasure of assisting our respected President in the collection of evidence on milk infections, the task proved so profitable that, by his encouragement, the investigation was extended in other directions and I present to you the results in one of these fields

According to Oesterlein's statistics, it is safe to assert that the average death rate during the first year of life is 188 out of 1000 infants born In England the average is 111 8, in France 223 2, in Italy 273 3 (Farr) These are mean rates for rural and urban districts In towns and cities the mortality is always higher, amounting to 33 6 per cent, as compared with a rural mortality of 27 8 per cent In some of the large cities the infantile mortality is simply frightful, having reached as high as

480 per 1,000 at Chemnitz,
360 " " ' St Olave,
320 " " " Glauchau,
280 " " " Paris
277 " " " New York,
276 " " " Brooklyn,
268 " " " Baltimore,
261 " ' " Boston,
256 " " " Washington,
250 " ' " Liverpool,
230 " " " Philadelphia

The still-births are excluded in the American statistics From these figures it appears, that, in many cities, out of every 100 children born alive, over one-fourth perish before the completion of the first year, but fortunately for the perpetuation of the human race, the average infant mortality all over the world is only about one sixth of those born

Of the twelve months during the first year of life, the first month furnishes the highest mortality, followed by the second, third and fourth month, next, by the twelfth month, this jump from the fourth to the twelfth month is quite suggestive, as it is the usual period of weaning with its attending danger from digestive diseases incident to artificial feeding, next to the twelfth month comes the fifth, sixth, seventh, eighth, ninth, tenth and eleventh months During the second and subsequent years the mortality gradually decreases, and of children between the age of 1 and 5 years, there die annually 37 out of 1000, a loss of 188 during the first year, with 148 during the next four years, making a total loss of 336 out of every 1000 children born

The mortality is greatly influenced by climate and seasons, as shown by a higher rate in the polar and equatorial regions with extremes of heat and cold Generally speaking, the mortality is higher during the cold months than during the moderate months, on account of the greater prevalence of diseases of the respiratory organs, but the hot months like June, July and August are the most dangerous, at least, in this country and Europe, on account of the disastrous attacks of gastro enteric diseases The fatal influence of heat and cold upon infantile mortality is well illustrated by the tables published in Dr Busey's essay on the "Mortality of Young Children," and while they apply to the city of Baltimore, because the essay was written at the request of the trustees of the Thomas Wilson Sanitarium for Children of that city, they are no less true of other large manufacturing cities

It would lead me too far to consider the various meteorologic conditions which influence the mortality rates as shown in these tables, but we should at least bear in mind, that sudden changes in temperature are especially liable to offend the peripheral nerves and thus cause an irritation, which is transmitted by reflex action to other parts of the body, where it may induce congestions, especially in the respiratory and digestive tracts During the heated term the blood too, owing to an excessive function of the skin, is deprived of some of its constituents, it is taken away too much and too long from the internal organs, the proper distribution of the blood supply is interfered with, in consequence the tone of the stomach, heart, brain and other tissues is lowered, appetite and digestion suffer, the red corpuscles are decreased and not only infants, but adults experience languor and general debility, but apart, from this, and more intimately connected with the subject, remains the fact that heat not only tends to diminish the power of resistance of every cell to disease, but also favors the development of germ life in the milk

This excessive infantile mortality has always been considered the opprobrium of the healing art Dickson asked in vain "How shall we prevent the early extinction of half the new-born children of men?" West truthfully asserts 'At least a third of all your patients will be children, and so serious are their diseases that one child in five dies within a year after birth and one in three before the completion of the fifth year," and Swayne pathetically exclaims "May it fall to the lot of some reader ere long to solve this startling problem "

While powerless to solve the mysteries connected with this subject, many of which are doubtless connected with the mortality laws in general, an attempt will be made to answer the practical question, Can they be reduced? I can not enter into details of infant hygiene, but must at least point out the fact that the mortality can be greatly reduced by improving the original stock, *i e*, the physique and habits of the parents, and placing them as well as their offspring under more suitable environments, especially with reference to fresh air, sunlight, exercise, suitable clothing and habitations and, last, but not least, proper food The influence of favorable hygienic conditions is demonstrated by Casper's statistics published in 1825, showing that the mortality rate among royal children was only 57 per 1,000, as compared with 345 per 1,000 among the infants of the poor Clay calculates that of every 100 children born in England, 90 will be alive of those born in aristocratic families, 79 in the mercantile class and 68 among the laboring classes The difference in the mortality of legitimate and illegitimate children is very great, and varies according to Uffelmann as follows

	Legitimate children	Illegitimate children
In France, mortality of	16 per cent	30 per cent,
" Austria, " "	22 9 " "	35 1 " "
" Sweden " "	13 0 " "	24 8 " "
" England, " "	14 0 " "	35 0 " "

But the most frightful mortality rates are everywhere furnished by the hand or bottle-fed children, amounting in Berlin 40 to 47 per cent, in Hamburg 29 4 per cent, and in Paris, according to Monat, it has reached as 70 to 75 per cent Professor Kehrer informs us that of 8,329 infants six months of age and under, that died in Munich between 1868–1870, 1,231, or nearly 15 per cent, had been suckled from the breast, and 7,098, or over 85 per cent, had been hand or bottle-fed

If we stop to inquire into the immediate cause of the excessive infantile mortality during the first twelve months, we find that about 40 per cent perish from diseases of the digestive system, about 21 per cent die from affections of the respiratory organs, next in frequency are the infectious diseases like diphtheria, scarlet fever, measles, whooping cough, mumps, scrofulosis and tubercular affections, rickets, etc The extreme incident of a mortality of 40 per cent from gastro-enteric disorders and the mortality of 2 5 per 1,000 from primary tubercular diseases of the abdominal lymphatics, can not fail to force themselves on our attention, and certainly points with more than mere suspicion to the fact that the morbific agent in these cases is introduced into the body with the food

Notwithstanding these startling arguments against artificial feeding, the facts are that there will always be a large percentage of infants deprived of their natural food, and the question therefore confronts us, What is the best possible substitute for human milk, the requirements of which are

1 That it must offer the same character and amount of nutritive elements, and in the same proportion as human milk

2 The nutritive elements must be present in the same assimilable form, of the same consistency, and should be introduced into the stomach at a temperature not less than 98 degrees F by means of suction and at proper intervals

3 This substitute must not contain any morbific or infective agent, whether originally present or introduced during the preparation or keeping of the same A moment's reflection upon the physiology of infantile digestion will at once suggest the propriety of rejecting all farinaceous foods before the expiration of the tenth month, except in very limited quantities, and previously converted into maltose by boiling as in barley water, but as milk is the natural food of all mammalia, few will be disposed to doubt that some modification of cow's milk offers the best possible substitute

Comparison of cows' milk and human milk the average composition of

	Albuminoids	Fat	Sugar	Salts
Cows' milk is	3 76	3 75	4 42	0 68
Human milk	2 00	4 13	7 00	0 20

Human milk contains, therefore, less albuminoids and salts and more sugars and fats, there is also a decided difference in the quality of the casein of the two secretions The addition of dilute acid to cow's milk precipitates the casein in hard coagula or lumps, while in human milk it separates into a fine powder giving the appearance of light flocculent curds, which readily dissolve in an excess of acid Since the coagulum in the same quantity of human milk is but one-fifth as large as that of cow's milk, this difference, which is solely one of compactness and solubility, can not fail to influence the digestibility of the two secretions, and explains at once why even moderate quantities of undiluted cow's milk are liable to overtax the digestive apparatus of the infant (Leeds, Starr, etc) In addition to this, and perhaps greater in importance, is the fact that human milk from a healthy subject rarely contains any micro organisms, while cow's milk is never free from bacteria and may moreover be the vehicle of infectious germs and other morbific agents. Apart from the fact that unscrupulous dealers not infrequently lower the nutritive value by skimming or watering the milk, Dr. Busey and myself in a joint contribution have elsewhere pointed out how the quality of the milk may be impaired by improper food and care of the animals, and how the milk may produce mischief if derived from animals while being treated with strong remedial agents, or as the product of diseased animals, especially those suffering from inflammatory lesions of the udder, tuberculosis and other communicable diseases. We have collected 138 epidemics of typhoid fever, 74 of scarlet fever and 28 of diphtheria, which have been caused by infected milk, and indicated the various ways by which it is possible for disease germs to be carried in this way. Permit me to direct your attention to a very common milk fault, which may be considered a source of constant danger in infant feeding and perhaps the most important factor in swelling the mortality rates of our helpless babes.

Every consumer of milk has doubtless observed the presence of more or less foreign matter found at the bottom of the vessel or bottle in which it is kept—indeed it is a matter of such common occurrence that it hardly excites our attention. Professor Soxhlet was perhaps the first to point out that these deposits are largely made up of excrementitious matter from the cow which, adhering to the udder of the animal, gained access to the bucket in the act of milking. Professor Renk, of Halle, brought this subject to the attention of the Section of Hygiene at the International Medical Congress in 1890, and few of his audience are likely to forget the valuable object lesson presented by him, consisting of filtrates of milk samples from different German cities, each representing the amount of filth contained in a liter of milk, and furnished at once a positive index of the degree of cleanliness observed at the various milk farms. The average weight *dried* at a temperature of 212 degrees F., of these sediments was 3.8 mgrs. at Leipzig, 9.0 mgrs. at Munich, 10.3 mgrs. at Berlin, and 12.2 mgrs. at Halle. These filtrates were so disgusting in appearance that we were not disposed to accept them as a standard for American milk, and with the courteous consent of the Health Officer, Dr. Woodward, Professor Hurd prepared filters from twenty-four specimens of Washington milk, taken at random, with the result that they presented even a greater amount of impurities, weighing all the way from 5 to 30 mgrs. per pint or quart, and as fecal matter contains about 85 per cent. of moisture, the weight of undried filth in the maximum specimen would have been about 180 mgrs. per quart.

Now it is not at all likely that the average American housewife would permit any one to throw this amount of filth into her milk pitcher and yet, practically, we suffer it to be done, and there is no law to prevent it. If these sediments are subjected to microscopic examination, we will find, as shown in the micro-photographs, prepared through the kindness of Dr. Reed by Dr. Gray, of the Army Medical Museum, that they are composed of epithelial *débris*, hairs of the cow, excrementitious matter, vegetable cells and fibers, organic and inorganic dust particles, bacteria, fungi and spores of every description, fully 90 per cent. of the bacteria found in such specimens are fecal bacilli, all of which is not only disgusting but extremely suggestive of danger. We know that the number of microorganisms in such milk is largely increased and bacterial development and consequent decomposition is materially hastened in such a medium. Dr. Plant, of Leipzig, found, as a rule, that in warm weather the so-called fresh milk delivered in the morning has already passed the period of incubation and is unfit for use by young children on account of the germ development, and of forty-seven infants whose milk supply was carefully investigated by him, eighteen developed digestive disorders and six died.

The greatest danger from milk of this class is the possible presence of tyrotoxicon and other bacterial products. Professor Vaughan believes that the former poison is developed by the growth of a germ which, under favorable conditions, multiplies very rapidly. The presence of the very filth referred to, a summer heat, and the pernicious habit of placing the milk before cooling in covered cans or bottles, perhaps dirty beside, constitute favorable environments for the production of bacterial toxins. The relation of this poison and of milk bacteria to cholera infantum and the summer diarrheas in bottle-fed children is gaining ground and will doubtless result in a great reform of our milk establishments.

Cow's milk, no matter how great the care exercised in milking, contains the germs which bring about fermentation and decomposition. These bacteria of different species abound in the atmosphere whenever the temperature is above 60 degrees F., cling to the udder and teats and even invade the lacteal ducts and finding there an excellent culture tube, multiply with great rapidity. Dr. Schultz has shown that the first half gill or so of milk obtained from the cow may contain 1,360,000 germs per cubic inch, while the milk drawn later is free from bacteria, hence we may safely conclude that the bulk of these organisms get into the milk from external sources, such as the air and dust of the stable, the hands and clothing of the milker, the hair or udder of the cow, the hay and straw, and last, but not least, the water, in which the milk vessels are washed, and with which the milk is not infrequently diluted.

Sedgwick and Batchelder have shown that with special precautions on the part of the milkman, the number of bacteria in fresh milk may not exceed 500 to 1000 per c.c., but when he uses the ordinary flaring milk pail, with more or less rough disturbance of the bedding and shaking of the udder, as many as 30,500 have been counted in 1 c.c. When we recall the fact that these germs during the heated term multiply with alarming rapidity, so that the average sample of Boston milk contains as many as 2,300,000 bacteria per teaspoonful, many of which are capable of evolving poisons, we can readily appreciate how the injection of such milk may give rise to the so-called summer diarrheas of infants and swell their mortality.

It has been proved, bacteriologically, that milk is not only a favorable culture medium for many saprophytic germs, but also for the germs of typhoid fever, erysipelas, tuberculosis, glanders, diphtheria, pneumonia streptococci and other pyogenic organisms, and this fact alone points at once to the necessity of a rigid control of our milk supply.

A review of the evidence on milk contamination, both in this country and Europe, shows that the laws which have been enacted to protect the public, deal largely with the prevention of milk sophistication, and even in this respect have fallen short of their aim Indeed, it is doubtful whether legislation in matters of this kind is as effective as public education The importance of a pure milk supply was recognized as early as 1878 in connection with some of the milk-cure institutes in Germany The system then originated has been improved by time and experience, and lately introduced into Boston, New York and Philadelphia, and appears to offer, by trade competition, the best solution of an important problem, those of you who are familiar with the surroundings of our milk farms and the habits of the average dairy employes need no arguments for the necessity of sanitary reform No family ever thinks of employing or keeping a cook afflicted with a communicable disease, and yet not the slightest restriction is placed, or question asked, about the persons who handle our milk supply, which is notoriously one of the most sensitive and susceptible articles of food to contaminating influences, but the absolute necessity of such milk laboratories are based upon the following facts

1 It has been demonstrated that milk may be morbific by reason of an abnormal number of ordinary milk-bacteria and the presence of saprophytic germs capable of producing toxins, such as tyrotoxicon, resulting in cholera infantum and other gastro-enteric diseases

2 Milk may be rendered unfit for use by reason of improper food and care of the animal, or while the animal is being treated with arsenic, copper, iodin, lead, mercury, tartar emetic, aloes, atropia, colchicum, croton oil, senna, strychnin, salicylic acid, turpentine, veratrum viridis and other remedial agents

3 Milk itself may be morbific as the product of a diseased animal Dr Busey and myself have elsewhere pointed out that inflammatory conditions of the udder and teats, especially the condition known as garget, are doubtless responsible for a large number of cases of pseudo membranous diphtheria and other septic infections The milk of animals suffering from acute specific enteritis, puerperal and other septic fevers, foot-and-mouth disease, cowpox, anthrax, pleuro-pneumonia, rabies and tetanus has also been known to prove injurious to the consumer

4 It has been proved by Ernst, of Harvard, that three out of twenty-five samples of Boston milk transmitted the germs of tuberculosis in the animals experimented upon, and Dr Fries found that the ordinary market milk of Copenhagen proved infectious in six out of twenty-eight rabbits, showing a corresponding degree of danger to delicate infants, and of which Dr Busey and myself have collected a large amount of clinical evidence

5 Milk may acquire infective properties after it leaves the udder of the animal, in support of which Dr Busey and the speaker have tabulated 138 epidemics of typhoid fever, 74 of scarlet fever and 28 of diphtheria, the analysis of which showed that the poison may reach the milk by soakage of the germs into the well water with which the utensils are washed, or by the intentional dilution with infected water, that the infection can be conveyed by animals wading in sewage polluted water, or by the dairy employes acting as nurses, or suffering themselves from some mild infection while continuing their usual duties, or are convalescents from the disease, that infection has taken place through the agency of scrubbing brushes, flies and other insects, exposure of the milk in sick rooms, or washing the patients with the same cloth used in wiping the dairy utensils Surely this is sufficient evidence, enough to show that something should be done to protect the public, and I believe this can best be accomplished by encouraging the establishment of milk depots, like the Walker-Gordon Laboratory of Boston, and of which Dr T M Rotch, of Boston, and Dr R T Taylor speak so approvingly

"The farm and herd are under the absolute control of the laboratory and are used for laboratory purposes only, the cows, their food, their stables, their pasture and their drinking water are subjected to the frequent, paid, critical examination of the best veterinary surgeon that can be procured in Boston The dairymen dress in white suits before milking, having each previously had a bath The milk pails are of glass, and the milk, after being aerated and cooled to about 44 degrees F in a tank of ice and water, is delivered at the laboratory in Boston within four hours after the milking The average and almost stable analysis of this original milk shows a percentage of

Fat	3 90
Milk sugar	4 30
Proteids	4 00
Salts	0 65
Total solids,	12 85
Total liquids,	87 15

"At the laboratory a ventilating engine keeps up a constant change of air and a hose keeps the enameled brick walls and stone floors wet to prevent contamination of the milk from dust, while it is being modified

"The whole milk, after being pasteurized, passes through a Stockholm separator, which makes 6,800 revolutions a minute and yields a cream of an almost constant 16 per cent fat It not only does this, but it removes all dirt that, from unavoidable causes, has gained access to the milk, thus yielding a clean skimmed milk practically free from fat, only 0 13 per cent remaining

"The modifier has, as a result, stable component parts of the original milk to work with, made up by analysis as follows

	Fat	Sugar	Proteids
Cream giving	16 00	4 00	3 60
Skimmed milk giving	0 13	4 40	4 00

"In addition to this, the modifier has a 20 per cent solution of sugar of milk, freshly prepared with distilled water each day, and is therefore able to put up correctly a prescription which calls for certain percentages of fat, sugar and the albuminoids After copying the formula or prescription in a book kept for that purpose, the "modifier" picks up a basket with as many compartments as meals are ordered, and fills each compartment with a tubular bottle holding the number of ounces ordered for each feeding After mixing the ingredients *en masse*, as ordered, each bottle is filled and the basket passed to the stopper, who plugs it with cotton The whole is then pasteurized for half an hour, and after proper labeling the basket is ready for delivery The delivery wagon is divided into two compartments, the back which is lined with zinc and easily cleaned is for the fresh milk and baskets, and the front for soiled tubes, baskets, etc, which are sterilized at the laboratory before being taken into the modifying room " (R F Taylor)

For a long time it was assumed that the composition of human milk varied with the age of the child, but Professor Leeds' long series of analyses show that after the function of lactation is once fairly established, the composition of woman's milk remains practically the same, and while the child receives more nutriment, day by day, it is in consequence of larger doses, rather than of a stronger quality This is quite in harmony with reason and common sense

Now if we wish to order a humanized milk as prepared at these laboratories, say for a child one month old, we would order the following mixture

Cream	f℥vi	180
Milk sugar solut 20 per cent	℥vi	180
Skimmed milk	℥ivss	135
Lime water, 1-20	f℥i	30
Distilled water	f℥vi	180

This is divided into twelve feedings, 2 ounces each As the infant grows older, the intervals are lengthened and the doses increased A child from two to five months old should receive eight feedings of 4 ounces each, and a strong child from five to eight months old, may receive from 6 to 7 ounces at each of the eight feedings, according to the indications which are best studied by the weight chart Professor Rotch uses lime water for the purpose of partially neutralizing the acidity of the gastric juice, in consequence of which the casein coagulates more slowly and the formation of firm undigestible curds is thus prevented Professor Leeds, instead of lime water, strongly recommends the addition of peptogenic milk-powder, which is a preparation of pancreatic lactose and alkalin milk salts, originated by Fairchild Brothers & Foster of New York

There is nothing strained in the requirement of an ideal milk supply, as good and sufficient reasons have been given, and by means of which we may hope to obtain such a standard of milk as will not only effect a decided reduction in infantile mortality, but will render the dissemination of infectious diseases through the milk supply a matter of history only Apart from these advantages the proper way to manufacture condensed milk suitable for infant feeding is to modify the milk before evaporation, a plan which, as far as I know, has not been attempted and is urgently called for

In the meantime, it will be well to educate the public in the matter of milk sediments, which can readily be seen at the bottom of the bottle after a few hours standing If we tell our dairyman the source of this pollution and how it can be prevented, something will be accomplished No milk supply is absolutely safe without pasteurization , and for infant feeding, until we can do better, I advise the following combination recommended by Professor Leeds

Milk	½ pint	240
Water	½ pint	240
Cream	2 ounces	60

Peptogenic milk powder one large measure This mixture should be placed on a hot range or gas stove and with constant stirring slowly heated for ten minutes to bring it to the boiling point , it is then removed and quickly cooled, and should be kept on ice and again pasteurized before feeding While milk thus prepared can never take the place of breast-milk from a healthy mother, it is very near in all respects to human milk and is perfectly sterile, as far as the ordinary disease germs are concerned

Prevention of disease is perhaps the central idea and object of sanitarians, but as hygiene also deals with the art of improving health, the question of a pure milk supply is not only important in the feeding of infants, but also the sick and invalids, and I trust, therefore, one of general interest to the profession

---

A CONTRIBUTION TO THE STUDY OF ATRESIA OF THE UTERINE CANAL AFTER THE MENOPAUSE, WITH A REPORT OF THREE CASES

Read before the Medical Society of the District of Columbia June 12 1895

BY HENRY L E JOHNSON, M D

MEMBER OF THE FIRST PAN AMERICAN MEDICAL CONGRESS LATE VICE PRESIDENT OF THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY PROFESSOR OF GYNECOLOGY IN THE MEDICAL DEPARTMENT OF THE COLUMBIAN UNIVERSITY DIRECTOR OF THE GYNECOLOGIC CLINIC IN THE CENTRAL DISPENSARY AND EMERGENCY HOSPITAL ETC
WASHINGTON D C

Some years ago, when I was learning my first lessons in clinical gynecologic practice in a hospital devoted especially to that department of medicine, I had the good fortune to see and make the diagnosis of atresia of the vagina with retention of menses in a young woman, and later on, a case of atresia of the cervix uteri in an old lady who had passed the climacteric period several years In the first case, operation was had, which resulted in cure The second case presented many symptoms, some local, but particularly manifested in the nervous system She was treated by medicines only and was not accorded an operation, and because no improvement followed was discharged from the hospital as a malingerer After several years of invalidism she died of some " obscure disease "

I was taught that operation in such cases was contra-indicated, because menstruation had ceased, fluid accumulation being impossible, and surgical interference was attended with much danger and a high mortality I will ask the society to bear with me while I give the history of some cases in which atresia of the cervical canal existed and for the relief of which operative interference was instituted with good results The bibliography on the subject is also presented for your consideration, and you will see that the subject has not received the attention which it deserves when you learn the number and standing of the writers who make no mention of the condition

HISTORY OF CASES

Case 1 —On March 21 of the present year, I was consulted in my clinic at the Central Dispensary and Emergency Hospital by Mrs L , age 54 years, white, married, one child, no miscarriages She was born January, 1840, enjoyed good health until 1866, though always thin and never very strong Family history excellent First menstruated during the thirteenth year that function being normal in every particular Married in 1863, and in due time was delivered of a healthy child Labor and puerperium normal Shortly after death of child three years later, she first complained of 'womb trouble" and consulted a number of physicians with more or less relief but was never entirely cured Menses ceased in 1886, since which time she has never been well In July 1887, after investigation and consultation she was committed to the United States Hospital for the Insane, and there treated for acute melancholia with hallucinations of persecution She was shortly discharged, relieved but not cured At that time she was very fleshy and bloated notwithstanding the fact that she frequently refused her food One year later she returned voluntarily to the hospital seeking admission in order to escape imaginary persecutors She was not re-admitted because of lack of authority She was at that time very thin and anemic Since the cessation of the menses she has complained almost constantly of backache, pain in lower abdominal region, bearing down' frequent and painful urination, constant leucorrhea with irritation and excoriation of external genitals Loss of appetite, coated tongue, indigestion, nausea, vomiting, meteorism and constipation, palpitation of heart, irregular pulse and vertigo Occasional fever, chills, and sweatings, nervousness, insomnia, prostration, loss of flesh, alteration in functions of special senses (sight and hearing), slowness of speech and mental operations Numbness, trembling and twitching in limbs Hysteria, hallucinations of impending danger and persecution and of sight and hearing

Examination very fat, color bad, pale and sallow, tongue coated and trembling, hands trembling, pulse rapid Is very nervous Abdomen enlarged and distended with gas, perineum lacerated to second degree, prolapse of mucous membrane of urethra, vagina inflamed, muco-purulent discharge, and prolapse of anterior and posterior wall Cervix uteri not discoverable by sight, entirely obliterated, no trace of os can be found, the supravaginal portion of cervix, however, can be determined by touch Uterus small, but larger than normal at her age, soft, retroverted, fixed, tender on pressure Both tubes enlarged, fluctuating, fixed and tender on pressure Diagnosis atresia of cervical canal, with retained fluid Operation decided upon

On March 24, in presence of some of the college class, I seized the vault of the vagina at the site of the cervix with a volsellum forceps and introduced a curved bistoury about two inches and a half deep, into the tissues where I had located the cervical canal This was followed by an evacuation of about two or more ounces of greenish pus more or less offensive in odor Subsequently irrigating the vagina with antiseptic solution and applying antiseptic applications on pledgets of sterilized cotton Drainage of pus continued for two weeks with the occasional passage of hard inspissated lumps of pus and epithelium Marked improvement in symptoms followed, with reduction in size of the tubes and uterus

April 4, in the presence of some of the hospital assistants, I removed a ring of cervical tissue from around the incisson, making an oval opening considerably larger than a normal os The mucus membrane intra and extracervical not stitched together, but the space allowed to heal by granulation Shortly afterward all nervous intestinal and circulatory symptoms disappeared, and patient felt quite well The local condition was much improved, though the uterus is still retroverted and somewhat fixed This condition had evidently existed for a long period and has been a most important factor in the causation of her varied and numerous symptoms, in fact, it might be no exaggeration to infer that the local condition has been the only lesion Within a few weeks, a prominent gynecologist here, after local examination, pronounced her free from any uterine disease and transferred her for treatment to a specialist in nervous diseases

It is interesting to note the number and skill of the physicians who have at different times had charge of this case, none of whom, however, discovered the nature of the malady This failure to recognize the lesion is due almost entirely to the lack of, or faulty teaching in, the text-books, and it is hoped that this contribution will stimulate special study of these post-menopause cases

Case 2—Consulted me at the hospital on June 6 last, Mrs W H, white, age 50 years, widow about one year, one child after marriage about thirty years ago Labor normal, no miscarriage, menstruated between fourteenth and fifteenth year Always strong and healthy and never had any womb trouble, so far as she knows Never had a vaginal examination made since the birth of her child Menses absent about four years and been sick during that time Complains of backache, soreness in walking, bearing down pains, frequent urination and leucorrhea, loss of appetite, indigestion and constipation Is very nervous and hysterical, with numbness and twitching in limbs, has been losing flesh for some time and can not sleep at night, has been having convulsions at intervals of two or three months for the past two years During the past four years she has consulted a number of physicians, all of whom told her she had no womb trouble and none of them thought it necessary to make a vaginal examination, because "she had passed the change of life," and as they thought, gave no symptom of womb disease Examination partial laceration of perineum, vagina inflamed, uterus small, soft and boggy, atresia of canal at internal os Sound forced through obstruction and two or three ounces of muco-pus evacuated Patient felt relief at once and described her sensation as if some tension or pressure had been removed She has continued to improve and now feels better than she has for years The same subsequent treatment was followed in this as in the preceding case

It is fair to assume that this condition exists more frequently than is usually supposed, and many similar cases may be under treatment to-day in the asylums for the insane The menopause being unquestionably a physiologic process should not be attended with the extraordinary symptoms which we witness in so many cases, the exception being found, I believe, in those where the normal changes are interrupted or modified by pathologic conditions

Clinically, all women passing through the change of life or menopause, do not have serious symptoms and when exceptional cases are observed, we should conclude there is a cause for their complaints, and a thorough local examination should be instituted In this department of medicine we should always bear in mind the possibility of this condition and its importance, when the lesion itself will be easily discovered and cured

PATHOLOGIC SPECIMEN

The unusual growth which I removed to-day, I will present for your consideration, because it presents an atresia of the cervical canal and obliteration of the infravaginal portion of the cervix and, practically, an atresia of the vagina at its extreme upper portion

Mrs B, age 58 years, married, several miscarriages Been in ill health for sixteen years Never had any flooding spells Has had an enlargement of the abdomen for years but never knew until now she had a tumor Has not menstruated for five years and was very irregular for five years previous Had a slight muco-sanguinous discharge two months ago, which lasted two or three days Has been confined to bed for six months on account of pain in abdomen and neuralgia of face Examination abdomen enlarged to size of nine months' pregnancy by a large irregular fluctuating nodular mass, which is almost entirely confined to the right lateral portion of the abdomen and extending from deepest pelvic region to diaphragm No trace of the cervix or os can be found From absence of flooding, the soft, irregular and fluctuating character of the mass and its location, principally in the right side and absence of cervix and canal, I diagnosticated multilocular cyst of right ovary, and excluded the probability of fibroma Just before making the incision, however, I gave reasons for excluding fibroid tumor, extraperitoneal (so-called abdominal) pregnancy, but admitted the possibility of the uterus being distended with fluid because of atresia of the cervical canal, though from the general character of the growth I did not believe it uterine, thinking that organ was atrophied On section mistake in diagnoses noted

Enlarged multiple fibroid was found with degenerated interior containing fluid, about two quarts offensive pus A soft, stringy, friable mass was discovered growing from posterior surface of uterus, completely filling up the pelvic cavity and forcing the viscera above The right Fallopian tube was about ten inches long, having attached to its fimbriated extremity a large fibroid ovary Two large soft masses containing fluid were next reached The first attached to the fundus uteri, the other superimposed upon the first, and attached firmly to the diaphragm above The peritoneal cavity was distended with a large quantity of cherry colored fluid The masses were attached or adherent to themselves, the parietal, back, and pelvic walls, omentum, liver and intestines The adhesions were freed, in some places thin layers of the cyst wall were removed and left attached to the intestines, complete separation being impossible Notwithstanding the extensive adhesions neither omentum or intestines were injured The tumor was delivered and the uterine and ovarian arteries ligated The mass was then easily excised, no hemorrhage following A very excellent intraperitoneal stump was formed and covered by peritoneum, a small fibroid being removed from the stump posterior to the bladder The cavity was perfectly dry when the incision was closed and the patient was placed in bed Profound shock followed, patient dying within an hour, never regaining consciousness The operation lasted one hour and forty minutes Tumor weighed exclusive of fluid thirty seven pounds

After opening the abdomen the operation might have been abandoned, but the patient requested that the growth should be removed at all hazards This case is a most instructive one, and shows how atresia with obliteration of the cervix may prevent an accurate diagnosis being made, and it is a particularly fit specimen to accompany this contribution After its removal the uterine cavity was found very much distended, presumably with gas, physometra, contained no fluid and measured nine inches in diameter But for the atresia and obliterated cervix the sound would have been of great assistance in diagnosis, and would have cleared up considerable doubt

The report of the pathologists of the hospital, Drs Gray and Parker, and that of Dr Walter Reed, U S A, Curator of the Army Medical Museum, is herewith appended, together with the photographs of the growth made by Dr Church, the resident physician

LIONEL LABORATORY, WASHINGTON, D C, June 28, 1895
Dr H L E Johnson

Dear Doctor —The sections from the tumor of uterus removed from Mrs B prove to be malignant in character The growth is a sarcoma of a mixed variety, it is composed of round and spindle cells of various sizes

The round white tumor which occupied the position of one of the ovaries is not malignant, it is a soft myxofibroma

Yours truly, W M GRAY,
Pathologist Central Dispensary and Emergency Hospital

WAR DEPARTMENT
SURGEON-GENERAL'S OFFICE, U S ARMY MEDICAL MUSEUM AND LIBRARY

WASHINGTON, D C, July 3, 1895
Dr H L E Johnson 1400 I St N W, Washington, D C

Dear Doctor —I beg to submit the following report of an examination of the specimen of uterus and appendages with tumor mass, which was received at the Museum on June 26, 1895

Dr Lamb furnishes me with the following gross description of the specimen, the uterus, which has been removed at the internal os, is somewhat pyramidal in shape and measures 6 5 x 6 5 x 7 The enlargement is due partly to hypertrophy and partly to the fibroid growth, which latter is situated in the left wall and projects into the flattened uterine cavity Within this fibroid there is a large cavity, with rough inner surface, filled with a recent blood clot Projecting upward from the fundus are several large tumor masses, one of which is hollowed out into a cyst, with thick wall and rough inner surface, the latter being overspread with blood vessels The right tube is adherent by its fimbriated end to the ovary, left tube normal Right ovary converted into a firm fibrous looking mass, 3 x 2 x 2 inches in diameter, left ovary normal in size and structure, shows remains of corpora lutea Posterior to the lower end of the uterus is a large shredded and brittle mass, covered on its upper side by the peritoneum of Douglas' cul de sac

Microscopic examination of sections taken from different parts of the tumor mass show the structure of a mixed cell sarcoma, richly supplied with blood vessels In several parts of the section there are seen cross sections of blood vessels with intact intima and which are surrounded by dense masses of round and spindle shaped cells, giving the picture of an angiosarcoma Microscopic examination of the small tumor mass occupying the position of the right ovary proves it to be a myxofibroma, there are no remains of ovarian structure to be seen Very respectfully,

WALTER REED,
Surgeon U S Army, Curator

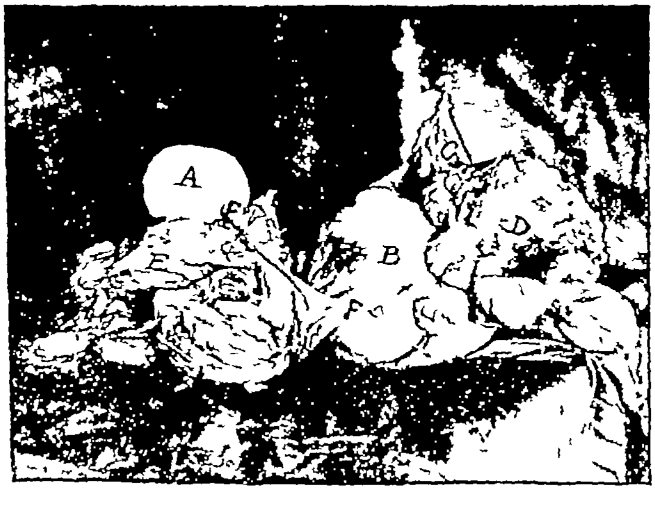

FIG 3 —Right lateral view
A Fibroid ovary B Uterus C Normal ovary and broad ligament D Cavity of abscess E Pelvic mass from dotted line F Long fallopian tube

CAUSE AND FREQUENCY

The question will be asked, How is the atresia produced, and how often does it occur? It is caused physiologically by the reduction in size of the uterus which takes place in normal atrophy, where the organ is reduced in some cases to a mere nodule Pathologically, from cancer, tumors, such as fibroids, catarrhal and other inflammations of cervical endometrium, extension of vaginitis into cervix (particularly senile vaginitis), small polyps causing endocervicitis, post-diphtheritic inflammations, the use of strong caustics, actual or electric cautery, trauma, and contraction or cicatrization following trachelorrhaphy

VARIETIES

The atresia may occur at the external os or internal os, or may include the entire cervical canal, and in some instances, the cervical canal is obliterated, together with the vaginal portion of the cervix, so that no trace of the cervix is to be found through the speculum, and its site is with difficulty found upon digital examination

DIAGNOSIS

The diagnosis is based upon the age and history, of the patient, the size and consistency of the uterus and tubes, and the obstruction discovered by the sound, or the absence of the cervix and os as described above

TREATMENT

Open the canal with sound or knife, followed by antiseptic irrigation and douches, keep the canal patulous, by dilation, or excision of cervical tissue when necessary Operate under strict modern methods Treat the cavity of the uterus locally with antiseptic applications and irrigations

DANGER

Danger arises from faulty asepsis, and perforation of organ by careless or bungling operators Failure to determine accurately the size of the uterus and direction of the canal will lead to error

Maryland and Virginia Medical Journal Richmond 1860, vol xv, pages 292–295, Art 4 Report from the Infirmary of the Medical College of Virginia (service of Dr McCaw), by Dr Thomas Hunter resident physician ' Case of Occlusion of Os Uteri " A negro named Agnes, age 47, *attempted an operation by a long curved trocar introduced* by Dr McCaw through the speculum and made to enter the uterus about the center of its os, was pushed to depth of one and one half inches without entering the cavity of the womb No further attempts were made 'and moreover, as that period of life had arrived when the menstrual function ceased, Nature herself might relieve her without the pain and risk of an operation " Had two attacks after this Ends article as follows 'In a few days after her last attack she left the Infirmary She has not been heard from since but in all probability she has been relieved from all further trouble by the total disappearance of the menstrual function "

Transactions Obstetrical Society of London for the year 1877, vol xix pages 176–177 ' *A Case of Suppuration of the Uterine Cavity resulting* from Occlusion of the Cervix " Dr Albert Lewis Galabin " Mary K, 43 years old, had been widow thirteen years Has had eight children and two miscarriages Menstruation ceased ten years ago Punctured from the vagina by a small trocar and fluid evacuated was pure pus Symptoms of general peritonitis soon came on, and the patient died after a few days "

The specimen exhibited shows the occlusion to have been due to the presence of cancerous deposit beginning about the internal os and not manifestly affecting the external part of the cervix

Transactions of the American Gynecological Society for the year 1879 Boston, 1880 vol iv pages 428-482 ' Premature Senile Obliteration of *the Uterine Cervical Canal,*" by Dr Henry Campbell, Augusta, Ga

Case 1—Senile obliteration of the cervical canal with accumulation within and distension of the uterine cavity Evacuation by incision and dilatation The patient a virgin Called Aug 4, 1876, to Miss N H, age 55, in consultation with Dr Amory Coffin, of Aiken, S C Operated Discharge intolerably offensive it more nearly resembled rotten egg effluvium than anything else amounted to nearly eight ounces Jan 26 1877 Miss N H came to Augusta for further treatment Stated the offensive discharge from vagina had continued but a few days after operation Jan 26 operated again, in ten days uterus appeared to be normal July 7, 1877, she was in an extremely low condition Died from irritative fever and exhaustion soon after

Case 2—Senile obliteration of cervical canal Patient a multipara April 4 1878 Mrs L Z, of South Carolina age about 58 years, mother of eight or ten children Youngest about 16 June 26 1878 Operated evacuated fluid nearly sixteen ounces about consistence of thickened milk, closely resembling in its offensive odor that previously described Recovery *Health* perfect in every particular

Atlanta Medical Register, 1881 82, N S, vol 1, pages 65 78 'Atresia of the Vagina and Uterus " A Clinical Lecture by Dr A F Erich, Baltimore, Md Professor of Diseases of Women, College of Physicians and Surgeons, Baltimore Surgeon in charge of the Maryland Woman's Hospital etc, says "Women who have passed the menopause sometimes suffer from an accumulation of mucus or muco purulent fluid in the uterus, due to the atresia of the os following endometritis or the application of caustics to the cervical canal In other cases the os may be closed by the formation of an epithelial stratum resembling a false membrane, completely occluding the os This condition is not infrequently seen in prolapse of the uterus *A sound can generally be pushed* through the obstruction and the passage afterward dilated " The indications in all cases of atresia accompanied by symptoms are to empty the retained fluid keep the tract pervious and restore if possible the functional capacity of the sexual organs

Chicago Medical Journal and Examiner, 1883 vol xlvi, pages 394 396 "Two Cases of Stenosis Uteri with Symptoms of Locomotor Ataxia," by Dr O Stroinski

Case 1—Mrs M N 52 years of age Operated Perforated cervix with trocar and dilated with laminaria tents then introduced intra uterine pessary After six weeks the phenomena of locomotor disturbance began to disappear and micturition was normal

Case 2—Mrs Anna W, 68 years old, unable to leave bed for the last three months Operated Improvement was more rapid in this case able to do housework after two months Ends as follows It is probable that pressure on the uterine nerves, caused by the agglutination of the uterine walls acts reciprocally on the nervous system of the abdominal part of the body and on that of the spinal cord "

Transactions of Obstetrical Society of London for 1885 London, 1886 Vol xxvii, pages 81 83 "Distension of Uterus from Partial Obstruction of Cervix." Dr A L Galabin showed the uterus of a woman, age 61, in which distension of the body with muco sanguineous fluid was found in association with a partial obstruction of the cervix The patient died six days after the operation for cancer of the breast The canal was obstructed by a median septum about three *quarters of an inch long*, occupying the lower part of the cervix and the summit of the vagina "

Clinical Lectures on the Diseases of Women, delivered in Saint Bartholomew's Hospital, by Dr J Matthews Duncan, 4th edition, London, 1889 J & A Churchill Lecture II, 'On Retention of Mucus," page 65 'Atresia may occur at any part of the course of the genital passage and I show you here an example of what happens to be the commonest acquired atresia—atresia of the internal os uteri—coming on in old age, and producing in the specimen I show you, a pyometra, the body of the uterus being distended so as to be a hollow globe capable of containing a small apple "

Zeitschrift fur Medicin Chirurgie und Geburtshulfe, n f v 1866, pages 22 84, 91 100, by Prof Dr C Hennig, Leipzig "On *Atresia of the Uterus*" says ' But exceptionally one meets atresia after the climacteric period Although in old age cases occur very often in which the internal os comes together, but does not close entirely (*hydrometra ex involutione oriunda*) Of 100 females who have passed the fiftieth year, one will find about twenty eight with atresia of the internal os and, doubtless the period between 69 and 70 years as the most prolific for the above named anomaly to make its appearance Notwithstanding, I do not mean that one dare perceive senile atresia as a physiologic condition "

Allgemeine Wiener Medizinische Zeitung 1878, vol xxiii, pages 257 258, 270-271, 280 "On the Impassableness of the Cervical Canal and Its Treatment " by Dr A Tripier, of Paris "That the internal os of the cervix is commonly completely obliterated, which Moyer has already laid stress on, that this growing together appears to be normal in old women Guyon found it thirteen times in twenty uteri of women from 50 to 70 years old

'Ueber Atresia der Nichtschwangeren Gebärmutter," by Franz Reder, *University of Rebstock, 1860 (Inaugural Dissertation)* Mentions senile atrophy of the cervix producing atresia

"Ueber Atresia der Vagina und des Uterus," by Wright Barnum, University of Jena, 1891 (Inaugural Dissertation) Under "Results and Symptoms" he divides them into three groups, in the last of which (c) "Results of Atresia After the Menopause " he says 'In the third period we have as a sequel an accumulation of mucus or pus This is the favorite time for hydrometra This accumulation is serous, mucus, etc " He advises operations in such cases

De L'Atrésie du Col de L'Uterus " Thésis by Elisée Ribard, Montpelier, 1869 Gives two cases Female aged 55 years, atresia internal os, operation complete cure Female aged 58, atresia due to abuse of coitus she died and an autopsy was held when condition was found

'Sur les Rétrécissements de L Uterus " Thésis by Dr J Henri Pouillot, Paris, 1861 Mentions senile atrophy as a cause of atresia Gives a case in a woman of 50 but does not say that she had ceased menstruating

' Essai sur la Rétrécissement du Conduit Utérin, Considéré Principalment au Point de vue du Traitement " Par Godefroy Thermes, Paris, 1867 Gives a case of a woman aged 53 years who was suffering from stricture of the neck of the uterus, due to a fibroid tumor of the body which extended to the neck

Klinische Mittheilungen aus der ersten Geburtshilflich Gynäkologischen Universitats Klinik in Buda Pesth, Uber die Jahre 1874 82 Mit Kurzer übersicht uber die Jahre 1869-74 Herausgegeben von Dr Theodor von Kezmarszky, Stuttgart 1884 page 237, under 'Gynäkologische Poliklinick " had 660 cases Gynecological cases, 608 Uterine affections 421 of which 4 were senile atrophy of the uterus

Die Königliche Universitäts Frauenklinik in München in den Jahren, 1884 1890 Berichte und Studien Herausgegeben von Dr F von Winckel, Direktor der Klinik Leipzig, 1892

For 1884 1890 inclusive 896 patients in gynecologic portion In 1884 56, 1885, 128 1886, 171 1887, 163 1888, 160, 1889, 202, 1890, 191 No cases

OUT DOOR SERVICE

Jan 1, 1885 to Jan 1, 1886, 358 persons 1886 1890, 2,185 patients treated: in 1886 446 1887 394 1888, 311, 1889 433 1890, 551 No cases

Rendiconto delle Sale di Ostetricia e di Ginecologia (Anno Scolastico, 1882 83) dirette dal Dr Giovanni Cosentino *Professore Pareggiato di* Ostetricia nella R Universita di Palermo e Ginecologo Primario dell 'Ospedale Civico Redatto dal Dr Giuseppe Giglio Palermo, 1884 Consultazione Nell 'Ambulatorio Di Ginecologia Treated 419 cases No cases of atresia after menopause

'Manual of Gynecology," Hart and Barbour 4th edition *London*, 1890 pages 266-267 'Atresia of cervix is rare as a *congenital* condition It is more frequently acquired, and results from the following causes Adhesion of granulations in cervical catarrh (after menopause) and round the base of tumors The practical point for the practitioner to remember is that it occurs also as part of the physiologic changes which take place after the menopause, 28 per cent of women above 60 years of age have *atresia of the cervix* (Hennig) " Page 319 'Senile atresia of the cervical canal is the result of a localized chronic endometritis This is one of the physiologic changes which occur after the menopause In some cases, however, it becomes pathologic accumulation of mucus more rarely of blood, takes place above the obstruction "

'Diseases of Women," by Dr Alfred L Galabin 5th edition, London 1893 Page 80 'Acquired uterine atresia usually affects some portion of the cervical canal It may also be the effect of cervical catarrh through adhesion of the granulations formed on opposite sides of the canal, especially when the passage is no longer kept patent by the flow of menstrual blood It is not uncommon, therefore, *in old* women, especially when prolapse of the uterus exists." Page 82 "After the menopause the uterus may be filled by mucus fluid (hydrometra) a condition usually resulting from acquired atresia of the cervical canal I have met with one instance in which the uterus became largely distended by pus in consequence of an atresia produced by cancer about the internal os Advises operation

"Treatise on Gynecology—Medical and Surgical by Dr S Pozzi New York 1892 2 vols Vol I, pages 582-583 "Acquired atresia It may also follow the cicatrization of ulcers of the cervix coincident with senile atrophy of the uterus finally it may in old women be due to a tumor in the cervix or lower portion of the body of the uterus It may occur spontaneously in old age The results of this obliteration vary as the patient has or has not reached the menopause If she has ceased menstruation the lesion usually causes no disturbance unless some cause of septic infection exists in the uterine cavity, causing an accumulation of pus (pyometra) or gas (physometra) I have seen two cases of pyometra from cancer of the body of the uterus and fibroma in aged women The treatment in such a case consists in incising or puncturing the cervix if it be necessary to disinfect the uterine cavity and then in meeting the indications called for by an existing fibroma or cancer

A Practical Treatise on the Diseases of Women by T G Thomas 6th edition Enlarged and thoroughly revised by Dr P T Mundé, Philadelphia 1891 Page 220 gives as a cause of acquired atresia senile atrophy The second is so very common in old age that Hennig declares that out of 100 women who had passed 50 years of age about 28 (over a quarter) suffered from it Results It might at first thought be supposed that uterine atresia occurring after the menopause would be as it usually is before puberty a matter of no moment As a rule this is so but there are exceptions to both rules In the old women a watery secretion sometimes takes place giving rise to hydrometra suppurative action may occur creating pyometra Advises operation

"A Practical Treatise on Diseases of Women by Dr J Thorburn London 1885 Pages 151 152 'It also occasionally happens that menstruation having ceased the occluded uterus continues to secrete a quantity of mucus fluid, more or less watery, which distends the organ giving rise to the same physical signs as hematometra (hydrometra) and in still rarer cases this fluid is or becomes purulent (pyometra) or decomposes giving rise to the presence of gases (physometra)' Advises operation

"A Manual of Gynecological Practice" by Dr A Dührssen Translated by J Taylor F R C S and F Edge M R C P, F R C S, London 1895 Page 85 In old women an atresia of the internal os is found analogous to the kolpitis adhesiva *This leads to the collection of* mucus or pus (Hydro and pyometra) Page 88 'Atresia of the internal os is treated by simply passing a sound or trocar through the obstruction

Practical Manual of Diseases of Women and Uterine Therapeutics by H MacNaughton Jones M D M Ch F R C S I and E, New York 1884 Page 325 1 causation 2 acquired The causes producing acquired atresia are cervical endometritis senile atrophy Advises operation if hydrometra etc

An American Text Book of Gynecology—Medical and Surgical edited by Dr J M Baldy Philadelphia 1894 Page 86 "Hydrometra which is more likely to take place in women of advanced age is due to the retention of the secretions from obliteration of the canal"

"*Landmarks in Gynecology* by Dr Byron Robinson Detroit 1891 Vol II page 190 'Hydrometra—it is a condition of late life when senile or other degeneration arise in the cervix

'Hand Book of Gynecological Operations by *A H G Doran F R C S* Philadelphia 1887 Page 338 gives Breisky's operation for atresia of the cervix

"Diseases of Women" by Lawson Tait F R C S 2d edition 1886 Page 75, in speaking of hydrometra, says "It is a condition almost entirely confined *ex necessitate* to women who have passed the climacteric period of life, and it very rarely causes the uterus to reach any great size, because the greater part of the secretion of the *internal mucus surface* is capable of resorption leaving behind only the more solid elements of the mucus Simpson *narrates a case unusual for it* in which he drew off large quantities of serous fluid from the cavity of the uterus which had been distended to the size of the fifth or sixth month of pregnancy, the fluid being due to a cancroid tumor at the fundus In such a case the symptoms would be severe and would necessitate a careful examination The first thought would be to eliminate the possibility of pregnancy and then to open up the canal

"A Text Book of the Diseases of Women by Dr *H J Garrigues* Philadelphia 1894 Page 407 "Closure of the uterus (acquired atresia) but the uterus may also be closed later in life *acquired atresia* Although not so rare as the congenital form, the acquired is still a rare affection Etiology sometimes it is simply due to old age and is especially found in old women suffering from prolapse of the uterus After the menopause the atresia hardly gives rise to any symptoms unless it is complicated with some other disease of the womb, especially cancer or fibroma

"A Hand Book of the Diseases of Women Including *Diseases of the Bladder and Urethra* by Dr F Winckel of Munich Authorized translation Edited by Dr T Parvin, of Philadelphia 1889 Page 462 Among the numerous causes of these are advanced age Page 465 Or if there is a retention of the uterine secretion after the menopause the uterine walls are sometimes thickened but not infrequently they are much thinner than usual Page 471 recommends operation Does not cite any cases

"Encyclopedia *of the* Practice of Medicine," edited by Dr H von Ziemssen vol x 1875 Diseases of the Female Sexual Organs' by Prof *C Schroeder Erlanger* Bavaria Senile atresia is mentioned

Hand Buch der Krankheiten des Weibes nebst *einer einleitung* in die Physiologie und Psychologie des Weiblichen Organismus von Dr Johann C G Jorg Leipzig 1831 Page 825 *mentions* hydrometra as occurring in women after the climacteric due to stenosis and atresia recommends operation

Lehrbuch der Gynäkologie von Carl C Carus Wien 1820 Vol I page 277 same as above

Spiegelbilder der Gesunden und Kranken Vaginal Portion und Vagina von Dr J Heitzmann Wien 1883 Page 173 mentions it as producing hydrometra in women after the menopause

Die Frauenkrankheiten Ihre Erkennung und Heilung von Dr R Flechsig Leipzig 1885 Page 124 under stenosis and atresia of the uterus mentions hydrometra as occurring after the menopause

Frauenkrankheiten von Dr C G *Rothe Leipzig* 1890 Page 243 "*Atresia* due to senile atrophy of the internal os is *not* pathological Page 184 'Hydrometra occurs mostly in old women who after the menopause, have atresia of the uterus

Die Krankheiten der Frauen von Dr Heinrich Fritsch, Braunschweig 1886 3d edition Page 191 "In old women cervical atresia occurs but seldom at the internal os But here menstruation has ceased so back of the atresia we have an accumulation of either mucus or pus (Pyometra senilis) Advises operation (First edition translated by Isidore Furst Wood's Library, 1883)

Hand Buch der Krankheiten der Weiblichen Geschlechtsorgane von Dr Carl Schroeder Leipzig, 1890 Page 413 Atresia, mostly of the internal os we find in old women very often Hennig found it twenty eight times *in 100 women over 50 years of age* ' Page 417 'With hydrometra the symptoms are not so intense, since the accumulation follows more slowly and the atrophic non functioning uterus in the dilation of its cavity is not answered by contractions Advises operation

Lehrbuch der Frauenkrankheiten von Dr F Winckel Leipzig 1890 Page 59 Cause old age ' Page 607 *If hydro or pyometra, operate*

Compendium der Gynäkologie, von Dr J Heitzmann Wien 1891 Page 41 'In the climacteric, *atresia of the internal os does not occur* very often only mucus accumulates with little or no pain (Hydrometra senilis) contrary to this mostly through gonorrheal infection a condition is caused, by which an intense muco pus is found in the cavity of the uterus" (Pyometra senilis)

Traité Pratique de Gynécologie et des *Maladies des Femmes par le* Dr J de Sinety Deuxième edition Paris 1884 Page 220 quotes Hennig

Manual des Maladies des Femmes par A Lutaud 2d edition *Paris* 1891 Page [illegible] 'Uterine atresia is sometimes acquired

CONCLUSIONS

From what has appeared above we may draw the following conclusions

1 Pathologic atresia of the uterine canal after the menopause is a condition which exists more frequently than is usually supposed, produces symptoms which have not been thoroughly appreciated, and may lead to error in diagnosis in some cases

2 The subject has not been carefully studied, or correctly treated in the past

3 The symptoms mislead by directing attention to the nervous system more particularly than to the true seat of disease

4 Atresia, or more correctly speaking, obliteration of the uterine canal, is a physiologic condition, only after complete atrophy of the body of the uterus and its endometrium

5 The uterus, during the menopause, and until completely atrophied, should be kept under careful observation, all inflammatory, catarrhal, and other abnormal conditions treated and cured, and the canal kept pervious by the passage of a suitable sound to facilitate drainage

6 All cases of atresia of the cervix, where complete atrophy of the uterus has not taken place, should be operated upon at once, even in advance of symptoms

7 Operation is beneficial by preventing or relieving distressing symptoms, and is absolutely free from danger when performed with modern surgical precautions

8 Many obscure symptoms occurring during, and after, the menopause, are produced by retention of fluid and *débris* from atresia of the cervical canal, which can be promptly relieved by the treatment advised

9 This subject is of the greatest importance and deserves a thorough investigation by the medical profession

PECULIARITIES OF COLOMBIAN LEPROSY

BY ALBERT S ASHMEAD, M D

NEW YORK

Leprosy in Colombia dates from very remote times, though no light is thrown over its origin According to Father Velasco, in the middle of the last century a lazaretto was founded in Cali

I find in an article of the *Anales de la Academia Nacional de Medicina*, Bogota, 1894, under the signature of Dr Alfredo Garcés, several points which represent Colombian leprosy in a rather peculiar manner

1 According to the information obtained from patients, and the opinion of the Doctor himself, the disease originates mostly, if not always, in a cold, exposure to rain, sudden cooling after strong perspiration, sojourn in damp rooms, especially during confinement, bathing in a brook being heated, passing from a warm climate to colder altitudes, etc These accidents are all followed by the wheals of urticaria From the urticaria, leprosy is developed Most of the patients attribute their malady to a cold Some say that they went out into the cold air, that they have been exposed to a draught, to a shower, that they have gone into the water while heated One of them said to me "I was sleeping in the evening, I was awakened suddenly and went out at once, heated and perspiring, into a cold hallway, I got a spasm

(urticaria), my skin thickened and my blood was corrupted ' Another said "While pregnant I lived in a damp room and was caught by a shower in crossing a courtyard, in the night my body was covered with wheals, I had fever and my blood was corrupted " Another said that she was grinding chocolate, and that she wetted her hot hands, that the hands thickened and were benumbed and that she got wheals Another, on her way, bathed in a brook, being much heated, and from that time she had thick feet and wheals One was a laundress, another a baker, another tapped liquors, etc In others the primitive cold is not discovered, but they have lived in contact with elephantiasis, or in rooms which had contained it Thus we see a mother and two sons affected, a father and three sons, two mothers each with her daughter, uncles with nephews One goes to the Valle del Caucas, he catches typhus there, he returns to Popayan and leprosy appears Another goes to the Valle del Patia, he returns to a cold climate and becomes a leper Others take a bath in Cauca or in Piendamo with their bodies heated, wheals come and the disease appears

2 In the general pathology of Colombia, scrofula is very common, "as common as tuberculosis is rare " Dr Garces says that he can affirm, surely not to exaggerate, that there is not in Colombia a family in which there is not at least one scrofulous individual In no place did he see so many strumous tumors of the neck, axilla and groin

"The gnawing lupus," says Dr Garces, "of slow and invasive march, appears frequently in its most alarming forms I have seen three patients in whom nearly the whole face had disappeared under the action of scrofulous ulcers, in another, the whole knee and part of the leg, in another, the face, the elbows and the neck had been invaded by lupus In the feet, in the legs, etc , are observed affections not unfrequently, and in a practice of six years I have observed not less than twelve lupi gnawing, most of them in women As to dermatoses of scrofulous nature, it is difficult to find a place where they are more frequent, eczemas, impetigos, purpura, breakings out on children's faces, acnes, are frequently observed Anemia and the lymphatic temperaments, with thick lips, stout and colorless forms, epistaxis, hemophilia are met at every step, in one word, scrofula reigns in Popayan, and its environs, as reign the paludic fevers in our heated lands (*terras calientes*), cholera in India, and yellow fever in New Orleans "

3 Garcés, while admitting the microbian theory, confesses that there is not one fact in support of it which might not be explained in some other manner

4 Leprosy is a disease of the nervous system, not engendered by microbes, followed by vasomotor disturbances, offering in a certain state a desired habitat for the bacillus, and afterward, susceptible of being propagated by the same microbe "We do not mean to evict the parasite from its domain, nor to deny its morbigenous action We want only to establish this clinical fact leprosy is a disease of the peripheric nervous system, which reaches the superficial nerves of some mucous membranes, through anatomic relations We can not be surprised that leprosy, being a disease of the nervous system, makes itself known chiefly by cutaneous lesions, for we see many of its affections accompanied by zona, pemphigo, trophic lesions, glossy skin, patches of anesthesia, etc "

5 In Colombia, scrofula is very often mistaken for leprosy, but the total absence of nervous disturbance is sufficient for the physician to make the right diagnosis

6 "There remains a disease rather common in Popayan which fills the public with terror, and gives to the subject the appearance of a leper, it is characterized by atrophies and reabsorption of the phalanges of some fingers and toes, by deformations, more or less important, which sometimes give to the extremities the form of a spider, of a claw, of an onion head, pes varus, globular in form, etc , mutilations which present zones of anesthesia and analgesia in distinct points of the extremities The lesions affect a certain symmetry and never pass from the foot, from the hand, or from the forearm, in no other part of the body is there observed anything abnormal, and those who suffer of such affection live long years without their disease advancing or generalizing itself They attribute their condition to a cold taken in their feet or hands when the body was heated I am not unaware that some of these subjects have become leprous afterward, but from this fact to the declaration that all do the same, there is a wide distance, patients like those of whom I have spoken are not lepers for me, as long as the microscope does not show in them the trophic lesions due to the bacilus of Hansen " Here is a case in point

DYSTROPHY OF EXTREMITIES

M P, aged 34, presents in the cheeks and on the forehead a rubicund color, and at that level the skin is rather thick Neither in the ears nor on the face, nor in any other part does it show tubercles nor even spots On the arms there are broad spots of a yellowish pink The right hand presents the following anomalies the interosseous muscles and the abductors of the thumb are in great part atrophied, the finger is almost without phalanx, and of the nail there remains only small fragments of the lunula, the finger seems thickened in its free extremity, looking like an onion's head, over the annular and middle fingers there is a pink spot, covered by some epidermic scabs, and over the nail of the middle there are well pronounced ulcerations, the annular and the little finger show a slight retraction of the flexor muscles of the phalanx, the hand presents in general the undulated aspect, perceptible in subjects who have suffered for some time of paralysis agitans The left hand has suffered the same atrophies as the other, the thumb has its phalangine retracted, while the other fingers are turned toward the back of the hand in their first phalanges, and doubled, claw-like, in the others, looking like a tiger's paw

In the inferior extremities there are callous patches in the anterior extremity of the metatarsians, where there exist also some pink spots, as well as in the trunk Points of anesthesia are not observed, except in the superior limbs, especially where the skin is a little callous, as is the case in the inferior extremity of the metacarpians, the left hand is almost useless, as it can not hold small objects, and, in general its touch is imperfect[1]

"M V, 22 years old, was grinding chocolate, got wet, and from that moment felt his hands benumbed, and pains with swelling in the feet He has on his body neither spots or tubercles and his brows are intact He has now four fingers of the right hand twisted and partly atrophied, in the left, the lesions are similar, but less pronounced, he feels much dryness in the hands and slight ulcerations are visible on the fingers On the right foot he presents toes—the first and the last—much retracted, while the others are raised, the skin in that region is thick, in the left these lesions are less pronounced but it shows cicatrices of old lesions Sensibility is very obtuse in the feet" (Garcés)

7 We come now to the essential point of leprous diagnosis Is it a parasitic disease? All the micrographers answer affirmatively, but it must be observed that in various cases of anesthetic leprosy the

---

[1] This man has been ill for twenty two years and offers no other symptoms, but those mentioned in this observation

leprogenous microorganism has not been discovered (Cornil and Babés) I do not know whether in Colombia the microphyte has been found in our patients, and in spite of that, I doubt no wise of its existence I believe that in most lepers the bacillus of Armauer Hansen exists, but I am very far from thinking that the same is the initial phenomenon, the agent *sine qua non* of leprosy What, then, opens the play? In my opinion the same thing happens with leprosy as with pulmonia, typhoid and other microbian diseases We live in close contact with them, we take them in our aliments and drinks, we carry them in our clothes, and we respire them continually, and in spite of all that, they do us no harm, unless some external cause puts us into a condition to be influenced by them In pulmonia and typhoid fever there is a perfect relation of cause and effect which is very well explained by Friedlander's and Eberth's microbes, but it is not the case in leprosy

The initial phenomena is a vasomotor paralysis, a shock to the peripheric nervous system, which prepares it for receiving the microphyte encountered in leprosy, but which alone does not constitute the disease The latter may exist, in the anesthetic form without microbes, and perhaps likewise in the initial stages of the other forms, in all, the nervous lesion and the local circulatory disturbance precede, and when these exist the microbe establishes itself, as a swarm of bees alights in the hollow tree which can contain them The microbe once admitted, helps to foster the disease, the nervous lesions continue being produced, new colonies appear and help the leprosy forward

"We are induced to make this observation by the following consideration the leprous microbe is of difficult cultivation, but once cultivated it develops with a rapidity which is in strong contrast with the slowness with which it works in animal economy On the other hand, the microbe must die in a short time, whenever its development is rapid Nevertheless, Cornil and Babés affirm that after having been separated ten years, a fragment of leprous skin was found to contain living bacilli, which is contradictory to their rapid development, unless we admit that, after desiccation, the parasite can remain asleep like the bed-bug and exists in a latent state for an indefinite time, but such is not the case in the organism, and that is all we have to consider

"Why does the organism invaded by myriads of microphytes wait so long before it announces their presence? In our opinion, because the soil is not equally well prepared, the affection begins in the territory of certain nerves, it propagates itself, and as long as the nerve is not diseased the bacillus does not establish itself in it, so it goes on spreading, until it reaches a number which can not be contained in the tract of the nerves and in the affected regions, the circulation then takes it up, transports it into all the organs, and the disease from local becomes general Thus we see that lepers who had lived many years without suffering great pains, nor lesions of rapid progress, suddenly, unexpectedly, present alarming symptoms, which, in a few days carry them to the grave

"In short, leprosy is a microbian disease, but whose primordial symptoms and lesions are localized in the nervous system and independent of the microbe *sometimes through life* It is possible to carry the bacillus of Hansen, without being a leper, and *vice versa*, there are lepers without bacilli " (Cornil and Babés)

8 "The microphyte," says again Dr Garcés, "has a very long existence and a power of resistance which protects him against the ordinary climacteric influences Spread in such profusion, it must, no doubt, surround us everywhere, and if it has not as yet been discovered in the atmosphere, it is because it has not been sought there, and because it is not known well enough In a land of leprosy we carry all about us the germs of the disease, and all we have to do, is to beware from making ourselves an appropriate soil for it The contagion can be made by the intermediary of the tainted objects carried by the lepers, but without aptitude for contracting the disease, there is no contagion The leper will infect us, if we are prepared for that, as the air would do, or any other object conducting the microbe, but without lesions of the peripheric nervous system and of circulation or to speak more clearly, without an entrance door, the disease is impossible Leprosy, therefore, is a disease which can be caught by contagion, or by contact with lepers, or without it, it is enough to be apt to receive the microbe, which may be caught wherever it is found, and even be carried on the body for a long time

"An instance is the case quoted by Barber, of a person operated on for a small sarcoma of the face, in which the microbe was discovered, who, in consequence of this operation, became a leper

9 "Contagion is not common and general, as in smallpox, scarlatina, measles, etc , because these diseases need no initial local lesions, the whole organism is their theater and they find it prepared, for this reason the individuals who escape them are rare *In leprosy the local lesion is indispensable, and as it is only rarely produced in the required condition, contagion is rare* " (Garcés) (Italics my own)

10 "Heredity of leprosy can not be admitted, unless the disease is admitted as a nervous disturbance, as a microbial disease it has no existence " (Garcés)

11 Prophylaxis avoidance of intercourse with lepers, especially those who have reached an advanced stage of the disease, and more than everything else to avoid living in closed places where lepers have resided, and using furniture or other objects which have belonged to them A guitar, a leprous dwelling have sufficed once to infect almost a whole family Insects may transmit the disease. bugs, flies, pulex penetrans, baths, beds, etc

"A young lady of the Department of Santander, traveling with her parents, slept one night at an inn in the same bed in which some nights before a leper had slept The bed-bugs pricked the young lady that night, and all the prickings were converted in a short time into lepromas and leprous ulcers The young lady was seriously ill and died in less than a year with all the symptoms of leprosy perfectly characterized " (Garces)

Disinfectants do little harm to Hansen's bacillus, but microbicides like camphor, corrosive sublimate, etc , may be used with advantage to wash contaminated clothing and hands

12 "In places where leprosy is at home it is necessary to avoid the quick changes of temperature which might stop perspiration, such are, baths in very cold water, being tired, draughts of cold air when coming from a hot room, or when just awakened, or coming

from a dance, or from the neighborhood of a baker's oven or from the ironing board Don't live in damp places, especially during confinement or any other illness, for experience teaches that after a confinement women predisposed to the disease, acquire it easily, and the same is observed in convalescence from grave diseases, as typhoid, dysentery, etc We have instances of all these circumstances It is of the highest importance not to change when you come tired or perspiring from the street, and you must not even enter the rooms before you have arrived at an appropriate temperature, it is better to wait in the hallway ' (Garces)

13 " Sudden changes of climate in a person already affected by the disease, only precipitate its development, and for that reason travels to *terra caliente*, which are often undertaken by lepers, benefit a few months, that is, as long as they are in the hot country, and exacerbate the disease when the patients return to a temperate and damp climate, like that of Popayan ' (Garces)

14 ' Whatever may be alleged on the other side, sequestration of the lepers is a necessity—for two reasons the first is that the leper himself flees from a society which hurts his feelings by its loathing and horror, and the second, is the duty of every civilized government, to guard the interests of the community, of which the most important is health All civilized nations have been alive to this Leprosy is contagious, contagion is effected by microbes which the *leper throws* off in his dejections, discharges through his skin, and scatters everywhere, wherever he lives This fact is sufficiently proved, and requires rigorous measures ' (Cornil and Babés)

But sequestration must not be used by half, to isolate a leper in his own house, in the midst of his family, is only to gild the pill to hide its blackness, without diminishing its effect, and makes us suppose one of these two things either the nature of the disease and the last observations on it are unknown, or that an official sanction is necessary in order that the sick people continue to live isolated in their houses, as heretofore, and are thus allowed to maintain among the population, centers of infection On the other hand, to condemn an individual to live cooped up in a room, breathing bad smells and an atmosphere vitiated and infected by those same germs which he discharges from his body, which continually penetrate anew into his organism, and aggravate his condition by auto-infection, to deprive him of exercise and free air is a thousand times worse than to sentence him to the galleys, or to the obscure dungeons of Carthagena

The isolation must be social, not individual, effective and not fictitious, for pity's, duty's, policy's and hygiene's sake, the lepers must be removed from the towns, but provided with all the accommodations required by their condition They must be considered as sick persons, not as proscribed individuals They ought to be established in colonies, with hospitals and all the means of living, they must *not* be disseminated but concentrated in localities where they can work and live in society, without being wounded by the talk of the vulgar, by the repugnance and loathing of friends and acquaintances, *in one word*, it is necessary to create for them a medium in which they will not be continually provoked to curse their fate, and where their lot will not be made more bitter than it is by itself It is not at all inhuman to thus isolate them, it is to give them the greatest boon which they can enjoy, it is to give them liberty, of which they are deprived in our society surrounded by suspicious eyes, victims of cruel speeches, in which the wretches are represented as monstrous beings, engaged in actively communicating to their healthy brothers the horrible plague with which they are stricken, and as guilty of actions so atrocious that the pen refuses to write them down " (Garcés)

15 The following may give the reader an idea of the way in which this terrible disease affects the feeling of the general public " Hygiene also commends this measure (isolation), 1, to protect society against a danger which, however far off it may seem, is too terrible to be disregarded, jeopardizes many interests, and is a permanent menace to the people, and 2, because the leper needs air, exercise, liberty, work, tranquillity to lift up his spirit, and removal from all that reminds him of better times and shows him too glaringly his horrible situation The choice of the site and the regulations for the colony must be carefully considered, so that neither the lepers nor the public have cause for complaint Each department must have its leper colony well provided with all the necessaries and perfectly regulated

" The lepers, far from being afraid to leave society will under these circumstances desire to do so, and although their disease will remain, they will have a more tolerable existence than that which they have now, and we shall in this manner stop and cut by the root, a plague which threatens our children and which would put hundreds of families into mourning Yes, there should be no hesitation When you least think of it, leprosy may knock at your door, and with or without your consent, cross your threshold A young, bright lady, 14 or 15 years old, the flower of the family, the mirror in which the father and brothers see themselves, the joy of the whole world, an image of candor and innocence, coming back from a visit, changes imprudently her attire, catches cold, to use the common expression She soon is covered with wheals, feels her limbs grow heavy, her ears itch and soon begin to swell, reddish or speckled spots invade her lovely face And now old women's medicine galore, physicians also are consulted, the recommended climates are visited, and, in spite of all that, the spectre pursues her course, he grasps his victim with both arms, consternation spreads in the family, society avoids the victim, slander prepares its arrows, and a hell of horror and suffering succeeds to the gaiety and to the fond illusions of past times And that is not all, the charming young lady who is the sister of the victim, her interesting brother, are looked at askance, the families shut their doors upon them, nobody will have any relations with a house in which there is a leper, the servants flee, business is paralyzed, sadness and despair reign absolute until comes the moment of separation, if isolation is imposed To depart! and to depart forever! To become an outcast! To drag out a life of privations, wounded to the very depth of the soul, having no consolation but God, no hope but eternity, exhausted by physical sufferings and tortured by the remembrance of those who were her own, and to whom she leaves a stigma of malediction It is horrible! It is heartrending! Can such a thing happen in a civilized land, in a Christian society? Can we remain impassive before such a spectacle? And how can we throw such an anathema on the future generations? Let us cut the evil without hesitation, for we can cut it

"The lepers who now exist are all Catholics, capable of bearing pain, full of resignation, sufficiently courageous, and virtuous to immolate themselves for their brethren, and suffer alone, the horrors of such a life as has fallen to their miserable lot All of them will be ready to leave their domestic hearths, when they think of the interests of future generations, and of their own families" (Garcés)

16 Dr Garcés recommends the extraction of the tuberculous lepromæ or galvano-cauterization

CONCLUSIONS

The most important point which I find in Dr Garcés article is the fact vouched for by him that leprosy not only very often is not accompanied by bacilli, in its first stage, but that the disease may run its whole course without *any microphytic influence* or presence Here again the autochthony of leprosy is raising its head It seems quite rational to admit that in certain moist climates a condition of nerves is produced, a polyneuritis which results in dystrophia of the peripheral tissues This would be a quite intelligible origination of the disease The occurrence of urticarial wheals would imply peripheric nervous disturbance as the very first symptom of leprosy, whether the disturbance be the result of cold, or of some infectious action on the skin, either sound or broken

The appearance of the bacillus by inoculation directly or through a host, marks a second definite period of the disease In lupus we have the same trophic loss of tissues as in leprosy, and the bacilli of the two diseases are not distinguishable except by this circumstance, that the leper bacillus is gregarious, while the other is more individual The microbes presenting themselves so differently may differ in a similar way in their action, this would explain the resemblance which exists certainly between these two diseases, and also the difference I should think that leprosy and lupus are the same disease with a difference

FIRE-PROOF ASBESTOS SURGICAL DRESSING

Read before McKean County Medical Society, Pennsylvania, Oct 1, 1895

BY EVAN O'NEILL KANE, M D
KANE, PA

I desire to present for your inspection a number of asbestos materials such as are commonly used in the arts, and to show you how admirably fitted they are to serve as surgical dressings Their softness to the touch and glistening silkiness of appearance commend them as being unirritating to the skin and soft and cleanly as a covering I hold that on account of their indestructibility when subjected to high temperature they are the only materials which, as dressings, can be rendered absolutely aseptic, while at the same time the variety of forms in which they can be manufactured enables them to fill all the requirements for which cotton fabrics are used in surgery, and with more satisfactory results

Appreciating the difficulty one is under in preparing dressings that shall be positively aseptic, and of retaining them so for any length of time, it had always been my custom to have them all thoroughly impregnated with bichlorid of mercury, iodoform, or boracic acid as shortly as possible before using them This procedure entailed much loss of valuable time and when operating in accident cases at a distance from my hospital I was always in dread, lest, during transportation to the scene of action or after being spread out among the flies and dirt upon the table of the farmhouse, or lumber shanty, or upon the cushion of a cabin car, a new horde of germs find entrance to them I am, therefore, satisfied that my present method of only using fire-proof dressings, beside saving much valuable time is the only safe one to pursue, and the results which I have obtained since making use of them have more than justified me, I am sure, in so believing

Asbestos dressings of all kinds can be kept as carelessly as if they were germ proof They may be carried in any parcel, paper bag or hand satchel, may be handled by dirty hands, may be spattered with blood, matter, the ejecta from the stomach, or any sort of filth, might be literally crawling with all the worst forms of germ life and yet can be rendered absolutely pure in less than two minutes by tossing them upon the coals or into the blaze of an ordinary kitchen stove or fireplace

My custom is now to carry with me in my buggy case a compact parcel (asbestos materials are very compressible) containing a sufficient supply of dressings of every sort, necessary to meet the requirements of general operative surgery When preparing for an operation, I lay out upon a table, board or chair, the amount and sort of asbestos material which I expect to use When the operation is completed and I am ready to apply the dressings, I instruct my assistant to place them upon the coals or in the flames of the nearest stove or fire and allow them to remain there a few moments, usually until they begin to assume a cherry red and then remove them with a tongs, fork or whatever else is convenient and spread them out beside me on a clean napkin or piece of paper Then I dust them with iodoform, aristol or other antiseptic powder, should such be desired, and, as they cool rapidly, proceed at once to apply them to the wound

When working in my operating room I have a specially constructed receptacle made of wire netting, not unlike a griddle, in which to retain the dressings while subjecting them to heat I find this unnecessary and cumbrous, however, to carry with me about the country, observing that an ordinary tongs or toasting fork answers the purpose

Asbestos goods are now manufactured in such a variety of forms that even from a country hardware store the surgeon can supply himself with the materials necessary to dress every kind of wound or injury

The form of asbestos most largely used by me as a dressing, because most nearly like absorbent cotton of any of the preparations made from asbestos, is asbestos fiber It is the same substance which is used to make luster in the back of fireplaces This material is as soft as floss silk or eiderdown, and its absorbent properties are much greater than those of absorbent cotton, an advantage which, aside from any other, recommends its use The only objection I have yet found to it is that its fiber is not as long as that of cotton, yet after all in many respects this is an advantage When thoroughly saturated with fluid, the surface of a mass of this material becomes as slippery as soap, a condition which I can not explain, as it is insoluble, but this certainly enhances its value as an application to sensitive surfaces, such for instance, as the inside of the orbit after the removal of an eye, or to the anus after an operation for hemorrhoids It is certainly the very best substance to apply as a first dressing after laparotomies, or as a covering to the stump after amputations

Next among the asbestos materials in usefulness will be found asbestos paper, or felt, as the manufacturers call it, which can be purchased by the yard for little more than ordinary wrapping paper It is manufactured in various thicknesses, from that of newspaper up to that of the heaviest binder's board Its quality also varies greatly, the texture of some being much smoother than that of others This paper may be made use of for bandages by cutting it in long strips of the desired width and length, for light wrapping paper it is sold by the pound in rolls of any length desired Such bandages are not strong enough to stand a great strain, as muscular contraction or the retention of a heavy weight, but will answer all ordinary purposes as a means of retaining dressings in position They are well adapted for holding inner dressings in place and wherever an aseptic bandage is necessary Being in fiber not unlike strong parchment paper, these bandages are more easily removed by the scissors than are those made by cotton cloth It is also useful in most instances where absorbent lint or gauze generally find their place It will prove valuable as an application or covering to raw surfaces such as those of open granulating wounds Its texture and tendency to become slippery render it unirritating, while its absorbent properties, which are equal to those of the best blotting paper, enable it to take up and carry away discharges and exudations which under rubber tissue, lister protective, wax paper or waterproof material would be retained For dressing wounds, I generally lay it directly upon the raw surface without previously dusting it with any antiseptic powder, in order to retain its full value as a non-irritant, it being already aseptic, and if there is much exudation I cover it with a layer of asbestos fiber which I dust thoroughly with iodoform or boracic acid By this means the discharge from the surface beneath being rapidly absorbed through the paper which has no irritating antiseptic in it, is completely taken up, carried away and disposed of by the overlying layer of fiber which, containing as it does an antiseptic among its meshes, prevents decomposition taking place

Asbestos wicking, packing and cord which are sold by the pound in rolls or balls are all admirably adapted for drainage tubes or wicks They are soft, pliable and smooth, slippery when thoroughly wet, and very absorbent I use them largely as a packing for abscess cavities and have found them answer admirably as a wick packing in the excavations left after the removal of dead bone, as within the shaft of the tibia, etc In such an event they should be thoroughly impregnated with iodoform or boracic acid and fed into the cavity with a dressing forceps, in the same manner as in tamponing with absorbent gauze They will be found to fill more closely every interstice and with much greater ease of application than the latter They are also more absorbent

As an aseptic sponge or swab, I have not given asbestos a thorough trial as yet The fiber, however, takes up moisture so readily and is so smooth and slippery when wet that I believe, were it made in little bunches covered with asbestos cloth, in the same manner that we now make cotton or wood wool swabs, it would be found most serviceable as a sponge, one which could be relied upon and absolutely free from septic material

Asbestos cloth, as at present manufactured, is too coarse for surgical uses I see no reason, however, why it can not be made sufficiently fine to answer all purposes for which cotton cloth is now utilized It would be found softer, more absorbent, and less likely to adhere to raw surfaces

My method of application of asbestos dressings does not differ materially from that resorted to in applying those ordinarily used, except that on account of their greater absorbent properties, they can be retained in position for a longer time without fear of sepsis or the collection of discharges about the surface of the wound

I will not enter into the details of my *modus operandi* in the application of these dressings, making use of them as I do, precisely in the same manner as of other materials for the same purpose

It is not my wish to urge the superiority of asbestos dressings either on account of their soft, unirritating texture or for their remarkable absorbative power, but simply because, as I have already pointed out, they are more readily, more rapidly and more certainly rendered aseptic than any other dressing materials

I have recently made use of asbestos materials largely, both in my hospital and outdoor practice having applied them to a great variety of wounds among which were laparotomies and various other capital operations In all cases the dressings were first subjected to great heat, usually until their edges became incandescent, before they were applied Frequently, it was not considered necessary to impregnate them with antiseptic powder, but in all cases the results proved equally gratifying Much time and annoyance in preparation heretofore necessary has been saved, a hot fire being always within reach When attending patients in the country I have, a number of times, re-dressed with the same dressing when by some neglect new material had not been brought with me for the purpose It only became necessary to wash them thoroughly to rid them of the more tenacious of the discharges and to then subject them to a cherry red heat to restore them to purity Repeated heating, however, seems to injure the pliability of the fiber, rendering it friable Still to the country surgeon, there is an advantage sometimes in being able to use the same dressing more than once, even if it is not as silky after its second heating

It must be admitted that asbestos materials, roughl manufactured as they now are, chiefly for the use o builders and mechanics, do not look as attractive a our snow-white surgical cotton, absorbent lint an the like Yet if Keen, Morton, Parke and othe leading surgeons were to become convinced of thei superiority, the makers of surgical supplies woul soon manufacture a line of them which would every respect be superior to the ordinary cotto dressings now in use

---

Sterilization of Catheters —A new apparatus has recent been demonstrated, depending upon the action of the vap of formalin Sterilization is complete the instrumen remain aseptic so long as they are kept in the apparatu gum, silk and metal catheters and a cystoscope were treated and remained uninjured by the process during eig months, and no irritation of the mucous membrane of t urethra resulted —*Therapeutische Wochenschrift*, Oct 6, 18

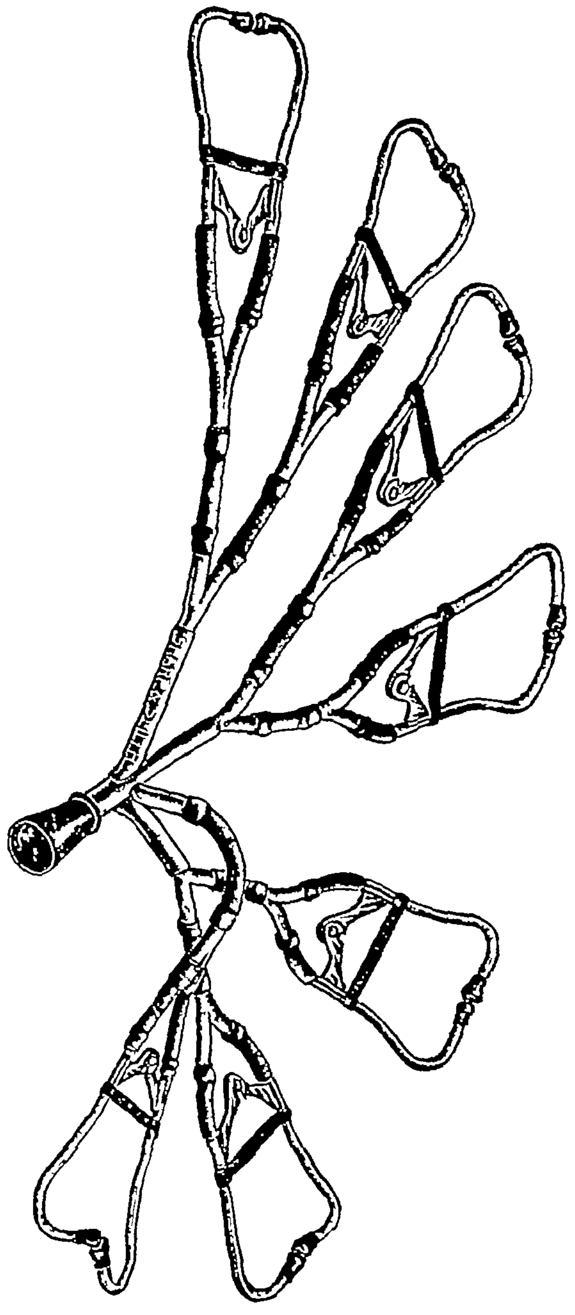
NEW INSTRUMENTS

A MULTIPLEX STETHOSCOPE

BY A M CORWIN, M D,

CHICAGO

In the February number of the JOURNAL I described a double stethoscope which I have employed during the past three years for class demonstration of physical diagnosis in Rush College In a later number of the JOURNAL, Dr H A Hare, of Philadelphia, described a multiplex stethoscope upon the same principle, but using tubes long enough to allow some sixteen individuals to listen at once



The double stethoscope makes possible the accurate demonstration of sounds which both instructor and student hear together—a multiplex stethoscope, if properly constructed, not only has this in view, but more, in the saving of time I have devised a multiplex stethoscope as represented in the accompanying cut, kindly furnished by Sharp & Smith, of this city I first experimented with long tubes A semicircle of twelve chairs, placed side by side, will bring a patient at a radial distance of about five feet, while the ordinary sounds of the heart and of normal bronchial breathing can be fairly well heard through this length of tubing, the less distinct sounds, as those of vesicular breathing and most of the adventitious sounds, râles, etc , are but poorly transmitted

After trying several shorter lengths and lessening the number of listeners, I have found that two feet is about the limit Tubes of greater length than this do not satisfactorily carry many of the sounds perfectly accessible to the ordinary stethoscope, and are therefore not applicable in the construction of a practical instrument for the class-room

The instrument here represented will accommodate six students seated in a semicircle close about the patient, who, if occupying a revolving seat, may be rotated as desired to make all parts of the chest conveniently accessible The demonstrator stands behind the patient and by a seventh stethoscope, connected at right angles to the main chest piece, is enabled to listen with the others and to manipulate both instrument and subject When the ear pieces are all in place there need be no handling of the apparatus by the students Necessary questions are readily heard and answered without the removal of ear pieces, so that there is no more difficulty in avoiding extraneous friction sounds than in the use of a single stethoscope

As to the size of the tubes used, all stethoscopes should be constructed so that the internal caliber of ear pieces and main arms of the instrument is about that of the external auditory canal, as exemplified in the ordinary Knight's stethoscope, after which the metallic arms of my instrument are patterned

In my experience, no better results can be obtained by a larger caliber than this If the caliber is smaller, there is to my ear a decided decrease in the distinctness with which sounds may be heard

Short pieces of stiff rubber tubing are used in connecting the metallic parts of the multiplex instrument The distance from the extremity of the chest piece to each ear piece is about 22 inches Further than this the relations of the parts is too obvious to need description

SOCIETY PROCEEDINGS

Tri-State Medical Society of Alabama, Georgia and Tennessee

Seventh Annual Meeting held in Chattanooga, Tenn

(Continued from page 960)

DR WILLIS F WESTMORELAND read a paper on

REPORT OF CASES, *a* TRACHEOTOMY FOR FOREIGN BODIES, *b*, CYSTOTOMY FOR STONE

He reported twenty seven successful operations for foreign bodies In all the first ring of the trachea was cut and the opening enlarged down as necessary Operated as early as possible The external incision was made large Muscles were separated, the fascia divided, vessels were ligated, so that no forceps were in the road If necessary the isthmus of the thyroid was divided and ligated No tenaculum was used in the trachea Instead of trachea forceps, the opening was held open with silk introduced with a needle having no cutting edge The foreign body was not probed for, but if necessary the wound was left open, in one case (cockle bur) for three days The mucus will sometimes prevent closure of the wound In closing the latter, the tissue under the mucous membrane is brought together with silk, using a needle having no cutting edge and the Halsted or mattress suture Thus the layers were all brought together In cystotomy for stone, he avoids rectal dilatation Hydrostatic pressure is used to distend the bladder, raising the water two feet This causes the bladder to bulge through the opening No tenaculum is used to steady the bladder, but it is held with two artery forceps, between which the incision is made as high as possible After removing the stone and flushing the bladder, the opening is closed with the Halsted suture and the closure tested by raising the water (an instant) three feet

Dr G A Baxter indorsed the position of the writer, but was attached to the medio lateral operation Stone is rare in this section, there not having been a dozen operations in fifteen years The trouble is more frequent in Middle Tennessee

Dr J A Goggans related a case in which the larynx was almost occluded at the site of the thyroid cartilage by a new growth so that he had to operate rapidly to save the patient Throwing the head back increased the difficulty of breathing, and the head had to be held forward and the larynx steadied with the tenaculum He said that suprapubic cystotomy was the operation *par excellence* for stone He was prejudiced against the low operations, as he was once called on to sew up a large fistulous opening between the bladder and the rectum in a case sent him He had attempted to sew up the opening by silkworm gut, operating through the rectum At the third operation he had divided the sphincter ani muscle and almost closed the fistula

Dr W E B Davis said that he was glad that both operations were fairly considered The results of the older surgeons were good They performed the low operation He found that statistics of the suprapubic operation were bad, because bad cases were selected for the operation A distinguished surgeon had so operated in a bad case to save his statistics for the low operation This shows how statistics can be doctored He thought it well to leave the wound open for drainage, for there is always disease of the bladder and we may have a new stone in a few weeks

Dr R J Triple said that his experience was limited to a few cases operated on for disease and advocated leaving the wound open for drainage As a guide he used a sound Did not fill the bladder with water, but washed it out before the operation In tracheotomy, he uses long scissors forceps and does not stop to ligate the vessels These held the wound open and saved an assistant

Dr Westmoreland, in closing the discussion, said that time was an important item, but that we had two minutes after the child quit breathing, for he could be resuscitated after that time He advocated cutting high in suprapubic cystotomy as the bladder was near the surface, being quite deep at the pubis The tenaculum was avoided, as the urine might be voided through the small opening The buried silver wire was used owing to the fact that it took several weeks for muscular tissue to unite and no other suture would last that long According to Gregg-Smith, without this suture 20 per cent of cases of laparotomy had hernia

It would make no difference if the peritoneum were cut in the high operation In these cases the wound was not left open, as they were not cases of disease

Dr J A Goggans, of Alexander City, Ala, read a paper entitled "Early Diagnosis and Vaginal Hysterectomy in Cancer of the Uterus" dwelling on the importance of prophylaxis, early diagnosis and early operative treatment by vaginal hysterectomy

Dr A R Robinson of New York, read a paper on

THE TREATMENT OF MALIGNANT CUTANEOUS EPITHELIOMATA

In cases where the diagnosis is not positive, iodids and mercury should be used The elements extend much further than is generally supposed, when they are excised, pathologic cells are left and we have so-called recurrence which is really a reappearance when the wound has been treated antiseptically Suppuration should be encouraged, as the toxin of the pus is more destructive to the epithelioma cells than the erysipelas toxin He opposed cutting and advocated the use of caustics The toxins had cured no cases though some may have been benefited The caustic should destroy the tissue quickly and thoroughly Mild caustics, as nitrate of silver, should not be used Caustic potash liquefies the tissue as much as would be removed with the knife, beyond this there is an inflammatory exudate which destroys the pathologic elements The cancer cells may extend deeper than could be reached with the knife, here the potash is preferable There is less deformity than with the knife, more than with arsenious acid Chlorid of zinc acts more slowly, suitable only in certain locations as near the eye, also in the papillary form previous to the use of arsenious acid Pain may be avoided by mixing it in a 20 per cent solution of cocain Arsenious acid has a more elective action on the cancer cells and should, as a rule, be used weaker than in Marsden's paste (2 parts to 1 of gum arabic) It may be used 2 to 1 or 1 to 1 This will not attack normal tissue in twenty four hours It should then be removed, and if there is not sufficient necrosis, applied immediately for sixteen to eighteen hours Cases should be watched for a year or two, as there may be a reappearance Arsenious acid may be applied to the lips if care is taken to prevent getting it into the mouth, but on the nose it is especially valuable on account of deformity

These papers were discussed together

Dr R R Kime said that it was unfortunate that cancer of the uterus is not diagnosed early Often the symptoms are not well defined and are very insidious, not being detected sometimes until the disease is so far advanced as to preclude operative measures It was not possible to get women to submit to repeated examinations as recommended by some gynecologists Every physician should insist on proper examination of all women near the menopause that present symptoms or indications of cancerous disease

Dr W E B Davis thought that these cases were overlooked as they were so insidious in their development Every case of diseased cervix should be treated and cured He advised removal of the uterus and appendages for cancer

Dr P L Brouillite asked as to the danger of systemic effects from arsenious acid

Dr Goggans said that wherever there was cancer there had been irritation, hence the necessity of removing every source of irritation and every pathologic condition as prophylactic

Dr Robinson had applied arsenious acid on a surface as large as the hand and had seen no systemic effect Marsden advised not over an inch square If seen early, caustics are all that is necessary in cancer of the skin

Dr I P Stewart, of Attala, Ala, read a paper on

HEMORRHOIDS,

in which he dwelt on the necessity of an examination under chloroform if necessary Where tumors are small, he used a solution of red gum as an injection into the rectum, if larger, they are destroyed with the clamp and cautery

Dr E P Johnson had treated cases successfully with injections of carbolic acid 2 parts to 1 of olive oil to which was added one-fourth grain of morphin to each injection

Dr I B Cowan alluded to the new operation of excising all the hemorrhoidal tissue These cases often fall into the hands of quacks who inject carbolic acid and give temporary relief He likes the old method of tying the tumors In a bad case, where there was no distinct tumor, he caught the tissue with a tenaculum and thus tied it, putting in fourteen ligatures The result was perfect

Dr R R Kime said that many hemorrhoids can be dissected out entire, and the wound closed by over-and over catgut stitch with excellent results, leaving no raw surface to granulate Where blood supply is marked, will require ligature at base Has devised a speculum by which rectum can be ballooned in knee chest position in the same manner as the vagina in gynecologic work

Dr G A Baxter insisted on varying the treatment in different cases Carbolic acid he considered dangerous. Could not examine without paralyzing sphincter Was always able to find a distinct tumor

Dr R P Johnson said that the tumors are destroyed if the solution is strong enough and they are completely filled

Dr R R Kime read a paper on "Synthetic Perineotomy in Lacerations of the Perineum," using the term to designate a method of dividing and dissecting without loss of tissue The redundancy is due to hyperplasia, a subinvolution, which will disappear when the cause of the laceration is removed The method was described in detail and cases cited

Dr W E B Davis said there was more in the man being familiar with the method he adopted than the operation It was important to differentiate between perineal tears and those of the posterior vaginal wall

Dr W E B Davis, of Birmingham read a paper on "Bile in the Peritoneal Cavity and How to Deal with It" He presented an experimental and clinical study of the subject The experiments confirmed the position taken before the American Medical Association in 1892 The constant extravasation produced peritonitis unless there was satisfactory drainage A considerable quantity would be walled off, just as would any other irritating fluid It was noted that where gauze was packed around the openings in the gall bladder or ducts, the animal recovered as a rule The field of operation was walled off completely and there was no evidence of general peritonitis Numbers were reopened in twenty-four to forty eight hours and this condition found He took the position that in obstruction of the common duct by stone, an incision should be made, the obstruction removed and drainage established without an attempt being made to close the opening, as these cases will not stand long operation

Dr E J Trippe, of Chattanooga, reported several cases of "Appendicitis," illustrating the necessity of early operation and the fact that some die, no matter when operated on, and the technique

These two papers were discussed together

Dr R R Kimp said that many cases would get well without operation, but it is very difficult to tell which By use of salines and disinfectants many can be relieved by unloading the colon, relieving the hyperemia and establishing drainage If a case is progressing nicely for some days and gets worse suddenly and seriously, then operate without delay Would advise against an attempt to remove the appendix when an abscess cavity was opened, which is walled off from the general peritoneal cavity

Dr C Holtzclaw had had fifteen cases of appendicitis but had never been called on to operate They recovered with an ice pack over the inflamed area Operation should be performed if there was any evidence of suppuration, elevation of temperature or collapse

Dr G A Baxter said that the danger was not in operating but in delay The question lies in a diagnosis between obstructive and catarrhal peritonitis When we have a distinct enlargement and induration we have obstruction

Dr R M Cunningham said that Dr Davis was departing from his usual teaching, as he had maintained that normal bile would not produce peritonitis In a large number of post-mortems the appendix was not found inflamed once in a hundred times Operation is indicated where there is pus, swelling and induration

Dr J P Stewart always cures his cases with salines He related a case of injury to the gall duct, followed by distension of the gall bladder He aspirated and got five pints of fluid and bile, the next day two pints, later one pint, the obstruction then gave way and the same fluid passed per rectum

Dr J B Murfree said that no operation should be made for appendicitis unless there was some indication, such as recurrence or gross local changes

Dr P D Sims did not recall a case of death from appendicitis which had not been operated on It might be required, but swelling and obstruction did not indicate an operation

Dr R H Hayes praised the high stand taken by Dr Davis in the surgery of the duct, and asked as to the preliminary and after-treatment In regard to appendicitis Telamon, of Paris, had published statistics giving 90 to 95 per cent of cures without operation An English author gave similar statistics, whether these are reliable or not he can not say Many claim that when one has an attack of appendicitis he has a constant source of danger in his belly A few years back this was the main indication for the operation, and in this view it seemed that the operation should be performed at any opportune time

Dr Davis thought the case of Dr Stewart not a case of distension of the bladder, but that a cyst had formed It was saved by the operation The after-treatment was the same as in other cases of abdominal surgery He thought catarrhal cases of appendicitis were common When there is obstruction, there is pain Each case should be treated *on its merits* Some need operation In general septic peritonitis the patient will die if operated on

Third Day

Dr J R Rathmell, of Chattanooga, read a paper entitled "Acromegaly—Report of a Case" He stated that Paul Marde first described the disease in 1886, his theory being that enlargement of the pituitary gland was the cause of the disease In the case reported, with the symptoms common to the disorder, there were two uncommon symptoms These were long continued abnormal rhythm of the Cheyne-Stokes variety, and the inability to retain food or drink on his stomach for three months before Both symptoms were accounted for by the enlarged pituitary body, which weighed 475 grains instead of 5 or 10 normally The author believes the disease to be one of trophic origin, producing changes in the bony system, especially of the feet, face and hands, that the enlargement of the pituitary body and the other ductless glands was the result, not the cause, of the disease

Dr W C Townes, of Chattanooga, read a paper on "Acromegaly," exhibiting specimens from Dr Rathmell's case, the enlarged pituitary gland and a part of the ileum with a diverticulum He reported a case now under treatment, a marked feature of which was that although 52 years old, there was no impairment of the sexual function He believed the disease to be due to the pressure on the brain produced by the enlarged pituitary body

Dr W G Bogart said that these cases were rare He had seen Dr Rathmell's case The enlarged tongue made articulation difficult, the labored breathing gave evidence of suffering The points of interest were the length of time required for the development of the disease, four years, and the question whether anything could be done if the diagnosis were made early

Dr E A Cobleigh asked if it were not possible that the condition was a persistent accentuation of a normal process and, if so, as to the cause He reported a case presenting some of the symptoms

Dr J Berrien Lindsley said that the paper was an evidence that the profession was advancing, and in this respect second to none A disorder was being discussed, the name of which had not yet got into the dictionaries

Dr J R Rathmell said that the first evidence of the disease was loss of strength and enlargement of the extremities He believed it a disease of the osseous system, especially of the feet, face and hands, but it affects the whole bony system, just as we have a pseudo-hypertrophic muscular paralysis The line of treatment was to build up the system, and use electricity He had got some comfort from the latter

Dr J B Cowan, of Tullahoma, Tenn, read a paper on "Water versus Atmosphere the Cause of Malignant Malarial Fever," and related observations where water from clear springs was evidently the cause of malarial fevers One case, where there were two springs connected under ground, the upper was healthful while those who used the lower had the disease A marsh between the two formed a nidus for the development of the miasm In almost every instance where well and spring water had been abandoned for cistern water, malarial fevers had disappeared In a village supplied by a well, all had the disease except one family who used other water So many similar instances had come under his notice that he invariably changed the water in his malarial cases If sterilized water were used malarial fever would be unknown

Dr E T Camp could not agree that malaria was in the water alone, some of the poison might be so absorbed But it was said that in the tropics one would get a chill by sleeping in the open air He believed the air was the principal medium

Dr C Holtzclaw differed from Dr Cowan, and related a case where there was no improvement on removing to a location where there had been no malaria for eight years

Dr W G Bogart said that water was one of the means of introducing the poison into the system, but not the only means In a certain neighborhood where different waters were used, all were affected, whether they were cleanly or not

Dr Y L Abernethy observed that when we have a wet summer we do not have much malarial fever The paper seemed conclusive that we get the disease from water, but why don't we have it every year and why don't we have it all the time? The old theory was that it was due to the heat, moisture and decomposition Bowling's theory was that it was due to water so confined as to prevent evaporation Now it is said to be due to a germ Whichever is correct, it is true that nineteen twentieths of the diseases of the West and South are due to malaria, so that we have to give quinin, iron, arsenic, mercury, etc

Dr Cowan said that the reason we did not have the disease every summer was because the heat did not develop the germ All cases of malignant malarial fever were due to drinking water In parts of the South, where malaria was formerly prevalent but now unknown, it was due to the use of cisterns In one case a party camped several years on a lake and had malaria every year, they escaped by taking their water with them, although sleeping in the open air as before

Dr J Berrien Lindsley presented a paper on "Prevention of Smallpox" He did not believe that one fourth of the people of Tennessee were vaccinated Doctors were not willing to acknowledge their inability to diagnose smallpox, hence mistakes occur In Little Rock the disease was under way six weeks before its nature was discovered A rule of sanitary boards is, in case of doubt to give the public the benefit of the doubt and isolate the case All suspicious cases should be sent to some public institution He related several cases where undiagnosed smallpox resulted in spreading the disease and causing death

Dr A Berlin said the microörganism of smallpox was not yet discovered and we were left to empiricism Jenner had done more for the race than Napoleon with all his wars In the Franco Prussian war more French soldiers died from smallpox than were killed in battle The disease was unknown in the German army, as the soldiers had been vaccinated

Dr Lindsley said *that the reason smallpox was dangerous* was because of the neglect of vaccination This fear did not exist when he was a young man starting in the profession The profession had not done its duty in the matter of insisting on vaccination

Dr E T Camp of Gadsden Ala, read a paper on "A Complicated Case of Obstetrics with Rupture of the Uterus' It was a transverse presentation The child was asphyxiated but resuscitated The placenta not being delivered in an hour, chloroform was administered and the hand introduced into the uterus when the rupture was discovered The placenta was adherent but torn away, morphin administered but *death took place in four hours* He thought rupture took place before the version and was spontaneous If the placenta could have been gotten away and contraction induced, the patient might have been saved

Dr Y D Abernathy thought it possible, if a laparotomy had been performed

Dr W G Bogart said that the three interesting points were 1, the time of the rupture, 2, the cause, 3, the absence of symptoms We would expect to have all the well-marked conditions of shock The strange thing was that that there was no pain, loss of blood or shock With the complications—mal position, adherent placenta and rupture of the uterus with bad surroundings, death was inevitable

Dr S P Stewart thought the patient died from hemorrhage, not from shock A post *mortem* would have been of interest

Dr D S Middleton thought the adherent placenta indicated a *diseased structure, and this caused the rupture* The administration of chloroform opened the months of the vessels and death was from hemorrhage

Dr C Holtzclaw said the only chance was to sew up the rent after doing a laparotomy

Dr J R Rathmell said that having a general adherent fibroid placenta, the only thing was to let it alone and re*move the entire uterus*

Dr. G A Baxter thought that an operation should have been performed quickly and the operator governed by circumstances after opening the abdomen

Dr R M Cunningham thought the Doctor did the best to conserve his own reputation The case would have died anyway To be in line with modern surgery, an operation should have been performed

Dr Camp said that there was nothing to indicate the condition until the discovery was made In a similar case he would not operate, as the adherent placenta would have produced death later

Dr R H Hayes Union Springs, Ala, read a paper on "The Nucleins and Their Relative Position in Sero Therapeutics" The nucleins are protoplastic or bioplastic, cell substance the bioplastic or primal unit of the organism, the cell life, vital and resistant force, a proteid granular, cell life substance in which all vital energy and cell life resistant force originated, and through which all animal nutrition *took place The nucleins* are proteid bodies residing in the tissue cells and the yeast of certain plants (animal and yeast nuclein) The former taken from the blood and lymphoid glands of the body, residing principally in the polynuclear blood corpuscles or leucocytes, the proliferation of which they have the power of *increasing* (leucocytosis) They are natural defenders, arresting and overwhelming all alien *or* disease *germs as they* enter the blood stream Vaughan and McClintock have developed them They are *gotten up in three forms*, nuclein solution from the yeast of certain plants, vegetable, nuclein solution from the tissues of the body, thymus, thyroid liver, spleen, etc., animal, from the tissue direct, protonuclein The principle difference between the antitoxins and toxins is that the toxins antidote or antagonize the poison or ptomaine formed by the presence of alien or disease germs, they belong to the class of albumin serums and they attack the germs direct as soon as *they reach the blood stream* The nucleins are more direct, if less powerful, and have the advantage of attacking through the leucocytes any or all germs entering into the system Reports are encouraging from eminent men The author reported an ulcer of sixteen years standing cured in four months Another case of ulcer of the ankle (both *non-tubercular) very greatly* relieved in same time He favors from limited experience, more general application of *the nucleins*

*Dr G W Drake indorsed the use of these agents on theo*retical grounds Intends to use them and await results

Dr C Holtzclaw cited the transfusion of blood as being the use of nucleins, salt water does as well The Valentine meat juice injected near an ulcer was found beneficial, but water does better *The* whole business was an advertising scheme These preparations should be under the control of the government

Dr R P Johnson, of Chattanooga, read a paper on "Treatment of Diphtheria," and gave his experience with established methods, indorsing especially the benzoate of soda He read a letter from Professor Klebs, who did not speak favorably of the antitoxin treatment, but asserted better results from anti diphtherin He described a method of steaming the patient with quicklime to loosen the membrane by covering him with a sheet

The following were read by title When Consumptives Should go to Colorado and Why? by I C Minor, The Diagnosis of Incipient Phthisis, by L P Barbour, Some Simple Procedures in Tedious Labor, by R M Harbin, Uric Acid as a Factor in Disease, by E van Goidtsnoven, Sympathetic Ophthalmia by Frank Trester Smith

The following officers were elected for the ensuing year

President, J B Murfree Murfreesboro, Tenn

Vice-Presidents R I Trippe, Chattanooga, R R Kime, Atlanta, R H Hayes Union Springs, Ala

Treasurer, Geo R West, Chattanooga

Secretary, Frank Trester Smith, Chattanooga

The next annual meeting will be held in Nashville, Oct 13, 14 and 15, 1896

BOOK NOTICES

A Manual of Syphilis and the Venereal Diseases—By James Nevins Hyde, A M, M D and Frank H Montgomery, M D Illustrated Philadelphia W B Saunders 1895 8vo, cl Price $2 50

This volume contains the "essentials' of the subject, and he who masters all that is so clearly expressed in this handbook will have little need for the more elaborate treatises We are very pleased to note the advanced views of the authors on constitutional infection *from* the *various* venereal diseases On this subject we quote from the introduction p 20

"The proposition once held can not longer be sustained that gonorrhea and soft chancre are purely local diseases as contrasted with syphilis, which is admitted to have systemic effects The generalized results of gonorrhea are in many instances too striking to admit even of question, and in *special cases* the perpetuation of the soft chancre for years, with the damage resulting to the rectum, vulva, abdominal wall and thighs, with the production of marked cachexia, often renders that affection one of even greater severity than the milder cases of syphilis"

This concedes about all that was claimed by the "unicists," except the comparatively unimportant *one of identity* That systemic poisoning could occur from the chancroidal ulcer, was a proposition bitterly fought by the "dualists," but in this case the long record of clinical experience has buried them out of sight The authors also assert that "the evidence of a remote antiquity for the venereal diseases in general, is very strong" The authors speak of the term "gonorrhea" as a misnomer, and very properly if we mean a specific urethritis, but the ancients used the term to describe the disease which we term spermatorrhea, and their use of it was entirely correct Paulus[1] says, "Gonorrhea is an involuntary discharge of semen, taking place frequently *without erection of* the privy member owing to weakness of the retentive faculty" This is the view held by all the ancient writers When we come to Fracastorius and the writers *of* the sixteenth century we find that the confusion in the nomenclature commenced in the dark period of literature The ancients were clear enough on the subject

Jahrbuch der Practischen Medicin—Herausgeben von Dr J Schwalbe Stuttgart Ferdinand Enke 1895

This annual of practical medicine has undergone since last year an unexpected change *Up to this year* it had, in com-

---

[1] The seven books of Paulus Ægineta, London, 1844

Dr. [illegible] Kelly Library
U. M. S. Medical College
39581.

mon with similar works, continued to increase from year to year in size so that it threatened to gain pathologic dimensions The present editor, Dr J Schwalbe, so well known as the editor of the *Deutsche Medicinische Wochenschrift*, saw the necessity of instituting certain changes in the make-up of the *Jahrbuch*, in the interests of the practitioner for whom it is published So judiciously have these changes been carried out, that it is in its new form probably the best handbook of current medicine that is anywhere published for the use of the practitioner While it fails to crowd all that has appeared in the previous year—good, bad and indifferent—into one voluminous book, or even into several volumes, it is far from being a short and limited compilation of only the most important publications, condensed within the scope of a convenient little volume On the contrary, on 625 octavo pages we find such a thorough and critical review of last year's medical literature, that probably few, if any, really important publications have been overlooked Much has been gained by the omission of special chapters on Anatomy and Physiology, as not pertaining to the requirements of a book of this character, but, while there has been some limit to the endless variety of publications in the different specialties, referring to compromises not yet settled among the specialists, to new theories, preliminary communications, etc, nothing has been omitted of the methods of specialism that have been or are likely to become of value in aiding the diagnostic or therapeutic resources of the practitioner,

It would be going too far to give a detailed account of the contents of this book A glance at them and the editorial staff will show what can be expected Following are the headings of the principal chapters General Pathology Pathologic Anatomy, and Bacteriology, by Professor Ribbert (Zurich), Diseases of the Nervous System, by Professor Seeligmuller (Halle), Psychiatry, by Dr Lewald (Berlin), Diseases of the Respiratory Organs, and Diseases of the Circulatory Organs, by Dr J Schwalbe (Berlin), Diseases of the Digestive Organs, by Dr Rosenheim (Berlin), Diseases of the Urinary Organs, by Professor Fürbringen (Berlin), Infectious Diseases by Dr Freyhan (Berlin), Anomalies of Constitution, by Dr Freyhan (Berlin), Surgery, by Professor Kolaczek (Breslau), Obstetrics and Gynecology, by Dr Czempin (Berlin), Ophthalmology, by Professor Horstmann (Berlin), Otology, by Dr Koch (Braunschweig), Laryngology and Rhinology, by Dr Michael (Hamburg), Skin and Venereal Diseases, by Dr Joseph (Berlin), Diseases of Children, by Dr H Neumann (Berlin), Climatology and Balneology, by Dr Butz (Munich), Materia Medica and Toxicology, by Professor Harnack (Halle), Forensic Medicine, by Professor Strassmann (Berlin), Hygiene, by Dr Pfeiffer (Wiesbaden)

The book is exceptionally complete, and the abstracts are short, concise and to the point A valuable aid in finding any desired article is—in addition to two complete indices of subject matter and names—a system of marginal notes throughout, giving the title of every article as well as the author It is but fair to state that a rare impartiality has been shown in the reviewing as well as in the selection of articles, American authors being well represented The general practitioner as well as the specialist will find this work a most fruitful source of information

Supplement to the International Encyclopædia of Surgery—Edited by John Ashhurst, Jr, M D, LL D, Philadelphia One royal octavo volume of 1,136 pages, illustrated by numerous wood engravings and a chromo-lithographic plate Cloth, $7 50, leather, $8 50 To subscribers to the entire set, cloth, $6 00, leather, $7 00, and half morocco $8 00

This volume is intended to supply the readers of Ashhurst's International Encyclopædia of Surgery a statement of such additions and changes as have taken place since the revised edition of that work was issued, seven years ago, naturally, therefore, the book is rather a series of surgical essays than a connected system of surgery Although the conservatism of the distinguished author leads him in the preface to eschew any claim to include "thoretic novelties," yet this dictum has not prevented the various contributors to the volume from presenting very much that will be new to many

As might be expected, the great activity that has taken place in bacteriology and surgical pathology has caused the re-writing of many topics, and in certain directions, such as that of cerebral surgery So much has been added that the usefulness of the book will by no means be confined to those fortunate possessors of the entire work

All the topics treated of have been brought quite up to date, and we only refrain from giving a list of the numerous titles on account of lack of space Suffice it to say that there is no attempt at padding in this great book of over a thousand pages, but the topics are those of living interest to the surgeons of to day

It is printed in the same excellent style as the preceding volumes of the series, and copiously illustrated

An American Text-Book of Obstetrics for Practitioners and Students, by various authors Richard C Morris, M D, Editor, Robert L Dickinson, M D, Art Editor, with nearly 900 colored and half-tone illustrations Philadelphia W B Saunders 1895 Cl, pp 1009 Price $7 00 For sale by subscription only

This text-book is written by well-known teachers in some of our leading medical colleges, and is a credit to American medical literature The publisher has provided good paper, clear and beautiful print with artistic illustrations Indeed, it is only just to say that no work heretofore published in this country surpasses it in these respects Some of the illustrations are works of high art See for instance (Fig 194 p 357), plate 48, facing p 754, and the reproduction from Sappey (Fig 2 plate 9), facing p 66 We can not praise the book too strongly, for it sets forth the subject in an excellent typographic fashion, and the text represents the latest teaching of the obstetric art The names of authors are printed with the list of titles in the table of contents, an arrangement which enables us to attach the proper responsibility to each statement made As a whole, the work covers in a fairly complete manner the department of obstetrics

Elementary Technique in Histology and Bacteriology, by Ernest B Hoag, A B, B S, and H Kahn, Phar M 1894 E H Colegrove, Chicago 12mo, cl, pp 130 Price, $1 00

This guide in elementary technique is intended for the use of medical and other students beginning work in Histology or Bacteriology, and is therefore divided in two parts, one to the methods of preparation of tissues and of examination in the histological laboratory, and the second part to bacteriologic examinations It is full of information and will be found extremely useful for beginners in laboratory work The authors have made a very clear exposition of the subject

The Anatomy of the Human Head and Neck—Graphically illustrated by means of superimposed plates, with descriptive text by Dr Schmidt English edition by William S Furneaux New York Thomas Whittaker, pp 16 Boards

This is a pictorial illustration of the head and neck, with an addition showing the structures revealed in a median section of the eye on a larger scale than the model There is also a descriptive text accompanying the plates It is a handy book of reference

The Medical News Visiting List for 1896—Weekly (undated, for 30 patients), Monthly (undated, for 120 patients per month), Perpetual (undated, for 30 patients weekly per year), and perpetual (undated, for 60 patients weekly per year) The first three styles contain 32 pages of data and 160 pages of blanks The 60 patient Perpetual consists of 256 pages of blanks Each style in one wallet shaped book with pocket, pencil and rubber Seal grain leather, $1 25. Philadelphia Lea Brothers & Co 1895

This favorably-known Visiting List has been thoroughly revised and brought up to date It contains sections on Examination of Urine, Artificial Respiration Incompatibles, Poisons and Antidotes, Diagnostic Table of Eruptive Fevers, and the Ligation of Arteries

A Thumb letter Index is furnished to subscribers at 25 cents' additional cost

The Medical Record Visiting List and Physician's Diary for 1896—New Revised Edition with Calendar Tables of Doses, Tables of Equivalents, Directions for Emergencies, Antisepsis, Disinfection, Special Memoranda, Cash Account, etc, etc 30 and 60 patients per week—bound in black or red morocco leather with flap, $1 25 and $1 50 Circular on application William Wood Co Publishers, New York

This is one of the most useful of the many excellent visiting lists on the market Its appearance is neat and attractive, and it is not too bulky The paper is good and the arrangement convenient

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman, Venetian Building Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor* and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago

SATURDAY, DECEMBER 7, 1895

THE NEW YORK COUNTY MEDICAL SOCIETY AND THE HOSPITAL APPOINTMENTS

The ninetieth annual meeting of this large Society was held November 25 in the New York Academy of Medicine, and the following officers for 1896 were duly installed Dr Edward D Fisher, President, Dr Frederick Peterson, First Vice-President, Dr J Henry Fruitnight, Second Vice President, Dr Charles H Avery, Secretary, Dr William E Ballard, Assistant Secretary, and Dr John S Warren, Treasurer

The retiring President delivered his valedictory address, and referred to certain matters that agitate the the local profession to an unwonted degree He alluded to the coroner's office as an effete and ridiculous institution He emphasized the point that the monopoly of medical appointive positions in the county hospitals by the three large medical colleges of the city, through the favoritism of the Commissioners of Charities and Correction, was an affair that this Society should unite to oppose Dr Grandin is reported to have said "I will tell you, gentlemen, why you have been forced to submit to this outrage of arbitrary exclusion from service in public institutions—it is because you do not work together I have seen the gradual development in this city of a great monoply in medical circles which, if not checked, will make it difficult for general practitioners to earn their living" He dwelt upon certain features of dispensary abuse, the catering of certain of the hospitals to persons in comfortable circumstances to the neglect of the really necessitous classes, and incidentally to the consequent plundering of the profession

The Secretary stated that a committee of the Society had called upon the Mayor, who, however, had refused to see this committee on the plea of being too busy, as at the time, the Secretary said, he was engaged in marrying a couple Dr Brill then formally introduced certain condemnatory resolutions Dr Frederick K Sturgis, formerly a visiting physician at the City Hospital, who had felt the edge of the knife under the new plan of appointment, seconded the motion in a spirited speech, which was vigorously applauded "I am not here as a sorehead," he is reported to have said, "but as a citizen to protest against the control of medical appointments by a monopoly Forty years ago this same Society investigated a secret medical order whose purpose was to control all hospital and college appointments It would seem as though history had repeated itself, and that we were called upon again for the same work Your practice is dividing, and every year you will find it more difficult to resist the operation of the powerful medical syndicate '

Dr A W Warden spoke to the resolution in a conciliatory spirit, arguing that civil service was not the needed remedy for existing evils Dr Palmer Dudley also made an effort to stem the tide of feeling, but without avail The resolution was passed with great unanimity, and upon motion of Dr J Blake White the following committee was appointed to deliver a copy of the resolution to Mayor Strong Doctors B S J Roose, W R Prior and Robert A Murray

Following these proceedings the Society considered certain matters relative to membership A well-known member, Dr Cyrus Edson, resigned, and his resignation was accepted *No reasons for this step* were assigned, but a fact of some significance was found in the printing of an old and somewhat disused section from the Society's ethical charter, to the effect that it is beneath the dignity of the profession for any member to affix his name to any certificate, circular or advertisement of any nostrum, mineral water, or other proprietary article intended to be used as a medicine or remedy in disease, or to any patented instrument or appliance that is intended for medical or surgical use The resigning member is reported as saying that "the Society is hampered by too many old traditions I have indorsed certain remedies which are beneficial to mankind, while by the rules of the Society I must not recommend them" Another matter was the expulsion of Dr Edward C Mann, a specialist in nerve cases, on recommendation of the Committee on Ethics

It would appear that there has been sudden and unlooked for stimulation of the ethical conscience of a body that has for ten years, or more, been in affiliation with the "no code" State Medical Society We trust that the change of heart is deep, sincere and not based on any alleged approaching bankruptcy of the New York profession

The control of the hospitals by the medical colleges of New York is to be viewed solely as a commercial enterprise, whereby the colleges are supposed to gain certain clinical advantages over any they now possess. The quickening of ethical conscience in the Society, whereby professional honor is appealed to by many who have heretofore objected to any ethical rules shows clearly enough the absolute necessity for rules of some sort. "No code," may be extremely interesting as a theory, but it invariably has commercialism as its underlying basis.

The action of the New York Commissioners is distinctly hurtful to the profession, because it introduces an element of discord and distrust, and breeds unnecessary antagonisms. The dismissal of fifty-two physicians from hospital appointments, without warning and without just cause, is not a spectacle to be viewed with pleasure, or even equanimity, by the general profession, and we feel sure that the colleges would have acted wisely if they had acted with less speed, and contented themselves with controlling the appointments as vacancies arose on the staffs of the various hospitals, without resorting to so radical a violation of the ordinary rules of courtesy between gentlemen.

THE ARMY EMERGENCY RATION

A valued Eastern weekly journal of medicine and surgery in its issue of November 30 last, under the heading of "The Army Ration," announces the failure of the recent efforts of the military authorities to decide upon an emergency ration for troops in active service. It gives an extract from a report of the experiences of a company of the Seventh Infantry on a march from Denver, Colo., while subsisting on an emergency ration proposed by the department board convened in Denver. The report shows that the soldiers started out with ten days' rations, but the campaign was brought to an abrupt end after four days of fifteen-mile marches. The food not only failed to satisfy the hunger or give strength, but seemed to irritate the stomach. After the first meal two of the enlisted men had to be placed under the surgeon's care. At the end of the second day thirty of the seventy men in the company were ill, and on the fourth day the whole command went into camp, and couriers were sent to town for hard-tack and ordinary coffee and bacon. Some of the soldiers were seriously ill with a stomach complaint and were confined to the hospital for several days.

Our esteemed Eastern contemporary explains all this by stating that "The stomach pouch is constructed with a certain capacity for food which can not be gainsaid by any chemical formula which mere human ingenuity may create or theoretical reasoning devise. Each of the varied and subtle processes of digestion must necessarily adapt themselves [*sic*] to the construction and functions of an organ that has a purely vital as well as a merely chemical duty to perform. The stomach must earn its living in its own way, as by such purely physiologic effort in bringing each and all of its mechanical, vital and chemical functions into play, it can best maintain its health, activity and usefulness. No prepared or concentrated food can relieve it of any or all of its activities in that gradual conversion of a legitimate quantity and quality of food that constitutes a natural and perfect digestion. In such an aspect a moderately full stomach is something more than a feeling. Its work must be distributive rather than restrictive. It must be healthfully distended with food, bulky enough to occupy spare places, otherwise its most important function is hampered, while for lack of mechanical stimulus the intestines become stagnated into almost helpless inactivity. Hence, it is easy to see how the experiments failed, and the victims paid the penalty of outraged physiologic laws."

All this might have been accepted as very sound physiologic doctrine had the troops been restricted to a concentrated food which had no bulk in the stomach; but as a matter of fact they did have in the ration sufficient to give that distension which is "something more than a feeling," for the smallest emergency ration tested in any of the eight Military Departments weighed 22.0 ounces, the largest 32.25 ounces, and the particular ration which caused the harfmful effects in the trial above mentioned 27.25 ounces; the nitrogen of the smallest amounted to 201 grains, of the largest to no less than 569 grains; the carbon of the smallest weighed 3,543 grains, of the largest 5,302 grains, while the value in calories of the smallest was 2,134, of the largest 3,526. From these figures it may be observed that none of the departmental boards went below an average diet as regards potential energy, in the proportion of nitrogen to carbon nor in the quantity needful to give the stomach its healthful distension and the intestines something to do to prevent them from being "stagnated into almost helpless inactivity." The stomach complaints affecting the Denver company were due to faulty preparation of the bean-soup tablet, not to a concentration of nutritious principles which gave the stomach no work. At the end of the second day thirty of the seventy men were ill. We believe that the stomachs of seventy men, taken at random, will submit to a total absence of food for two days without the supervention of any serious stomach complaint. There must have been something other than mere want of bulk to occasion the sickness of the men, and this something is readily found in the insufficiently cooked starch grains of the bean-soup tablet. Samples of the same ration have recently been used by the Seventh Cavalry in Arizona without any harmful affects, the only unfavorable criticism being that the soup wanted more seasoning.

We consider it premature to call the efforts of the military authorities a failure because one experiment of one of the eight departmental boards gave unsatisfactory results Instead of being failures, we understand that the experiments of these boards have contributed much to the perfection of an emergency ration for the troops, and it is probable that a board of officers, in which the line of the army and the medical and subsistence departments will be represented, will be convened in Washington to consider their reports and to make the necessary investigations and experiments which will lead to the preparation and adoption of a suitable emergency ration

A THEORY OF THE CORTICAL PATHOLOGY OF PERMANENT DEMENTIA

The JOURNAL has more than once had occasion to notice the suggestive articles that appear from time to time in the medical press, inspired by the latest discoveries in the finer anatomy of the nervous centers A very recent one of this class is that of DR H J BERKLEY in the *Medical News* of November 9, entitled, "A Theory of the Causation of Permanent Dementia" Referring to some former researches which demonstrated that non-medullated nerve fibers are hard to find in the cerebral cortex, he assumes that probably there are none there that can be strictly classed as such, and that the conduction must be direct through the fiber to its termination, that naked axis cylinders ought to be a physiological impossibility in the cerebrum, for, if present, they could only give rise to irregular overflow of stimuli with corresponding confusion of thought and action The so-called psychic cells, however, the pyramidal cells with long and short ascending processes, are distinguished from the other cortical nerve elements by the richness of their protoplasmic processes in lateral buds or gemmules, and it is through these, he holds, that the axons influence the protoplasm of the dendrons and the cells, their uncovered free endings coming into close contiguity with these gemmules, whose function it is to receive the nervous impressions of the fibre to transmit them to the protoplasm of the dendron and thence to the cellular body When these gemmules fail in their function through disease, or are lost, the proper conduction of the nerve impulses, according to DR BERKLEY's theory, is impossible The first result is confusion in the psychic functions and, with the advance of the morbid process, coordinated thought is finally abolished as far as the affected apparatus is concerned, and with the extension of the process terminal dementia is the result The gemmule-bearing protoplasmic processes of the nerve cell being the most sensitive and vulnerable are first affected, but later the cell body itself degenerates and plays an important part in the production of the ultimate result The axis cylinders themselves are less vulnerable to morbid or toxic influences and their involvement only occurs after the practical death of the body cell, and therefore plays no special part except in case of actual inflammation DR BERKLEY has seen neurons with their processes totally degenerated and their cell bodies reduced to stumps, with their axis cylinders as perfect as those of the normal cell

In short, therefore, the theory of BERKLEY as to the pathology of dementia is as follows The conduction of nerve stimuli to the cell corpus is through the medium of the lateral gemmules of the protoplasmic processes, that these are specially liable to injury from toxic or morbid influences, and are the first portions of the neuron to atrophy and disappear in certain diseases of the brain, that with their atrophy and consequent loss of function we have, first, confusion and incoordination of psychic functioning, and finally with any widespread degeneration of the cortical elements a permanent dementia ensues

His conclusions have been deduced partly from examinations of human brains and partly from experimental investigations on animals He gives with his paper a reproduction of micro photographs, showing the normal primordial process of a well-educated man taken from an autopsy immediately after death, and of a corresponding process from a subject of terminal dementia, showing the atrophy and absence of the dendritic gemmules

DR BERKLEY's theory is at least as probably the correct one as any that has so far been advanced, and it is as well supported by clinical and experimental observation as any It has, moreover, the merit of going no further than is reasonably warranted by the facts he adduces, and does not, like the ingenious and suggestive theorizing of ANDRIEZEN, attempt to demonstrate the pathological conditions of all the elements of the mental derangement, requiring the assumption of special psychic functions in this and that particular cortical layer for which no adequate proof is or can be afforded It is simply a theory of the pathology of general mental failure, apparently based upon well observed facts, and because it attempts no more is the more worthy of consideration It is not merely a suggestive theoretical paper, but is an actual and valuable contribution, and if confirmed by further investigation will be a real addition to our few positive facts as to the cortical pathology of mental disease

VALERIANATE OF QUINIA AS A PROPHYLACTIC OF MALARIAL FEVER

DR LUIS CENDRERO contributes to the *Boletin de Medicina Naval*, August, some clinical facts regarding the use of this remedy at a very trying location in the Gulf of Guinea, in West Africa The writer's station is on the little island, or cluster of islands, of Elobey, north of the mouth of the Gaboon river, and is under the Spanish protectorate His position in charge of the marine service at that point has afforded him ample opportunity to compare the efficacy of the different drugs principally preparations of quinia, against unusually severe forms of malarial fever "So severe is this scourge, says the translation of Dr Cendrero's report in *Sanitarian*, November, "that without exaggerating, all or very nearly all the persons connected with the Spanish service seem to be sent to the hospitals for malarial patients, once, twice, and even three times a month On account of this grievous situation I was led to try some medicinal prophylactic measures, and having used the sulphate of quinia in doses of 20, 30, and 40 centigrams a day without success, looking for a more satisfactory result, I obtained much benefit from the use of the valerianate of quinia, although, even with the use of this salt, I did not obtain all the relief I desired"

The summary of his experiments is as follows "The first consisted in giving a third of a gram a day of the valerianate of quinia, causing it to be taken in my presence in the morning, a little after breakfast, to one-half of the men who formed the corps under my care, leaving the other half without any treatment At the end of the month, the result was that the seven who had no prophylactic treatment suffered from the fever, some twice, some three times during the month, while those who were treated remained entirely free from fever

"The second test was exactly the reverse of this—the seven who were treated with prophylactic remedies during the preceding month were left during the present period without treatment, while those who were not treated now took the remedy as their comrades did the month before Those without medicine were attacked, some more than once, and of those now treated only two had very slight attacks

"The third and last observation was somewhat different To all the men, doses of valerianate of quinia were given as above, during the month and a half, and the result of this test, as compared with the condition before preventive measures were employed, was that only eight entered the infirmary with fever, while in the same time, previous to treatment, there were thirty-five, the average being taken for the whole year, with malarial fever"

Before these experiments, the sulphate of quinia and the preparations of arsenic had been used with variable and not fully satisfactory results The sulphate, used in a systematic way, had many successes to its credit, and in the absence of the valerianate operated well, especially in the recrudescence of endemic fevers

HYPNOTISM AGAIN

The *New York Medical Record* takes exception to an editorial in the Journal of Nov 16 on "The Passing of Hypnotism" It says that to say that hypnotism has had its day is a curious statement to make considering the interest that German physicians are taking in the subject at the present time Does Dr Shrady refer all medical questions to the standards and practices of German physicians?

The "practical side" that has come to stay, understanding thereby the legitimate use of suggestion in therapeutics, was duly recognized in our editorial, the "sensational side," or the production of hysteroid disturbances of consciousness for therapeutic ends, or practically and essentially what is known both in and out of the medical profession as hypnotism, is, the editor of the *Medical Record* states, certainly dying out In our editorial we did not go so far as that, but merely said its day had probably well passed its meridian There are still some able men experimenting with it and advocating it, and his statement in strict truth is a little premature As a prophetic anticipation it may pass, but it was hardly so intended

Undoubtedly hypnotism will fill a large place in medical literature, it is an attractive subject in many of its relations But as regards its usage as a therapeutic agency, not including in it the legitimate use of waking suggestion, history is repeating itself and its medical standing, we hold, is on the wane Its most enthusiastic advocates can not claim any general support for their views except in so far as a very limited and somewhat dubious utility may be admitted

CORRESPONDENCE

Illinois State Board of Health vs Northwestern University Woman's Medical Society

To the Editor—In the July issue of various prominent medical journals appeared a letter from the Illinois State Board of Health accompanied by a set of resolutions adopted by said Board The undersigned, the Executive Committee of the Faculty of the Northwestern University Woman's Medical School, having carefully investigated this matter desire to make the following report, in order that no injustice may be done to the State Board

The resolutions adopted by the State Board are as follows

Whereas, The Faculty of the Northwestern University Woman's Medical School adopted a set of resolutions, criticising the Illinois State Board of Health for having issued to three non-graduate students of said college the State certificate entitling them to practice medicine, whom they claim were not entitled to receive them, and charging the Board with having adopted a lax policy in numerous other instances, thereby seriously detracting from the usefulness of the Board, and

Whereas, Although the resolutions were "ordered to be placed before the Illinois State Board of Health," they were furnished to the various medical publications of the country simultaneously with their presentation to the Board, and before the Board had an opportunity to make any defense, and

Whereas, The said college had not made any investigation of the methods or policy of the Board, and could not be in possession of information upon which to found such serious charges, and

Whereas, The Secretary of the Faculty admitted to the Secretary of the Board that the resolutions were adopted without due consideration, and were not so applicable to the present Board, and

Whereas, In the past two years no certificate has been granted to any applicant upon any average rating less than 80 per cent on all branches, and the questions and examination papers, and a tabulated record of all examinations are preserved and are matters of record in the office, and

Whereas, It is not in the province of the Board to adopt any policy regarding the admission to its examinations of non graduates, the law prescribing that "non graduates shall submit themselves for examinations" and further prescribing that "the examinations shall be of an elementary and practical character," therefore, be it

Resolved, That justice demands that the Faculty of the Northwestern University Woman's Medical School, and all others interested, inform themselves as to the methods and policy of the Illinois State Board of Health in conducting its examinations, with a view to the establishment of the charges made, or of making such withdrawal, alteration or explanation of the charges as the facts may warrant, and *further, that the Faculty inquire as to whether any individual* interest or personal animosity prompted the drafting and circulating of the resolutions

(Signed) B M Griffith, M D
Sarah Hacket Stevenson, M D

The original resolution of the Faculty of the Northwestern University Woman's Medical School, to which the above refers, is as follows

Whereas, *On three occasions* within the past three years, the Illinois State Board of Health has licensed to practice medicine in this State students who have not properly qualified *themselves for such duties* and whose incompetence has compelled us to withhold the degree of Doctor of Medicine, and

Whereas, By common report we are informed that the State Board has adopted a similar policy with reference to numerous other persons, therefore,

Resolved By the Faculty of the Northwestern University Woman's Medical School, that the State Board of Health be requested hereafter to make its examinations so rigid that persons incompetent to obtain the degree of Doctor of Medicine from first-class medical colleges can not obtain licence to practice from the Illinois State Board of Health

Resolved, That the State Board of Health be urged to do all in its power to secure a modification of the State law, so that the privilege of examination for license to practice in this State can only be obtained by graduates of recognized medical schools in good standing

Resolved, That for the protection of the lives and health of our people, we believe it is the duty of the State Board of Health to do all in its power to prevent the entrance into the medical profession in this State of any persons not properly qualified, and further

Resolved, That, in the interests of humanity and medical science, we believe the State Board should make its standard of qualifications as high as that of the best medical colleges in this country, and that it should do all in its power to aid and encourage the efforts of the profession and the people for thorough medical education and higher requirements of licentiates and for the degree of Doctor of Medicine

(Signed) Marie J Mergler, Secretary

Replying to the State Board of Health, we beg to state that after thorough investigation we find that not only the three incompetent undergraduates referred to in our resolutions, but others similarly conditioned from our school, have been granted license to practice medicine, and we find further that it is believed by medical teachers and other members of the profession, that the State Board of Health has frequently conferred the license to practice in the State of Illinois on undergraduates whose requirements were not sufficient to enable them to obtain the degree of Doctor of Medicine from the medical schools of the State that are recognized as in good standing by the Board of Health

This policy is not calculated to advance the standing and active usefulness of the medical profession, or to protect the public from incompetent practitioners The Board of Health and its individual members have been *repeatedly* urged to discontinue this practice but as these remonstrances have heretofore proved unavailing, the Faculty of the Northwestern University Woman's Medical School determined by public action to bring the matter to the notice of the profession, hoping thereby to obtain their aid in securing a better policy by the State Board

The Board is in error in thinking that the Faculty acted hastily or without investigation, for it was familiar with the fact of the licensing of incompetent persons, not only from among *its* students, but among students of other schools This practice has been in vogue since the first organization of the Board, but the last cases were, if possible, more flagrant and inexcusable than those which preceded them

The Secretary of the State Board of Health is mistaken in stating that the Secretary of the Faculty of the Woman's Medical School said that the resolutions were adopted without due consideration, though another member of the Faculty did admit to him that, if his statements were correct, the criticisms were not so applicable to the present Board as to former Boards, however, the Secretary is not aware that the practices of the present Board differ materially from those followed by earlier ones composed of a different membership

Shortly after the original resolution was passed, the Secretary of the State Board of Health interviewed several members of the Faculty, and on one of these occasions stated, in extenuation, that the particular individuals now in the State Board of Health constituted an entirely different Board from that of former years We are aware that the State Board of Health changes more or less from time to time in its personnel, but one of the signers of the series of resolutions under consideration has been a valued member of the State Board for many years, and we can not understand why he should have allowed such a practice as granting licenses to incompetent persons at any time, without a vigorous protest

If the policy of the Board as now constituted is better that of former years in this respect, it appears to be only a degree, for the same official, in one of these interviews, stated that no applicants for license were now passed on an average of less than 85 per cent on all branches, whereas the resolutions printed above place it at 80 per cent, but he also admitted that formerly applicants were passed on a grade of 50 per cent It must be borne in mind that the grade obtained on an examination depends upon the nature of the questions, the fairness with which they have been given out, the honesty with which they have been answered, the care taken to prevent cheating, the fairness with which they have been marked, and the qualifications of the examiner Questions may be peculiarly easy, proper care may not have been exercised to prevent them from falling into the hands of the applicant beforehand or to prevent communication by the interpreters or others at the time of the examination, or the examiner himself may have marked too high For example An examiner who knew very little of anatomy might consider a very poor paper on that subject of exceptional excellence

The Secretary of the State Board explained to us his efforts to prevent cheating among applicants for midwives' licenses, and he led us to infer that similar precautions were taken for those taking the medical examinations He asked if we questioned the honesty or ability of certain members of the Board of Health, but, as we stated to the Secretary thereof, we can not understand how an ignorant person, unable to obtain a grade of more than 35 or 40 per cent on an ordinary examination for the degree of Doctor of Medicine, can come before the State Board within three, six, nine or even twelve months afterward, and pass an excellent examination Teachers know that it is impossible to acquire a knowledge of medicine with this rapidity Therefore, the inference would be that 80 or 85 per cent by the State Board of Health is equivalent to little more than 35 or 40 per cent by the colleges If this is so the State Board should raise its mark still higher, or mark more carefully

It was also admitted in one of these interviews, that one of the persons referred to was in no way fitted to practice medicine, but it was claimed that the answers obtained from her in examination were excellent, and that the Board had no option in the matter As a possible explanation of the excellence of the papers handed in by ignorant applicants, it was suggested that any one could "cram" and pass a good examination on two or three subjects, and it was explained that it was the custom of the Board of Health to give those taking their examinations full credit for each and every branch in which they succeed in obtaining a passing mark, though they *might* utterly fail in all others It will be readily seen that in an extreme case this policy would allow an applicant to pass one branch at a time every three months (we believe the examinations are quarterly), until the whole had been gone through with, while at the time the license was granted the person might not be able to obtain a general average of over 25 per cent We are not informed, officially or otherwise, that the Board has even yet taken any step to correct this bad practice

It is stated in these resolutions that the Illinois State Board of Health is not at liberty to adopt any policy regarding the admission of non-graduates to examination, that is, persons mentally or morally unfit to practice medicine must be admitted to the examination if they apply, but certainly the law can not require the Board to issue licenses to such persons In our resolution we called upon the Board, if there were defects in the law, to make all proper efforts to have them remedied We have not been informed, either publicly or privately, that it has made any effort in that direction

In the resolutions by the State Board of Health we are told that the law demands that the examination shall be "elementary and practical" Though the law under which the Board of Health acts prescribes that examinations shall be of an elementary and practical character, it does not prescribe that the Board of Health shall confer on incompetent persons the privilege of practicing medicine in Illinois, and the Legislature surely could have no such purpose in view when it enacted the law If an applicant can pass a thorough examination in the elementary subjects of anatomy, chemistry, physiology and materia medica, and a practical examination in pathology, obstetrics, practice of medicine and surgery, he would be able to pass the examination for the degree of Doctor of Medicine in almost any of the recognized colleges throughout the United States

We deeply regret that the resolutions of the State Board of Health failed to remove the belief that their methods are faulty, and we personally know another student who obtained license to practice during the past year who was unable to pass the examination for the degree of Doctor of Medicine this last spring We have informed ourselves so far as possible of the methods and policy of the Board of Health, and we gladly embrace this opportunity to do it exact justice The Faculty of the Northwestern University Woman's Medical School does not need to disclaim the suggestion that any individual interest or personal animosity prompted the drafting and circulation of the resolutions This faculty, individually and collectively, is friendly to the Illinois State Board of Health, but in the matter under consideration it has been constrained, as a matter of public duty, to question the wisdom and propriety of some of its acts We will gladly be the first to give it credit when it corrects its faulty practice, and we will gladly aid it in securing any necessary legislation for elevating the profession and for the benefit of the people

Serum-Therapy in Leprosy

NEW YORK, Nov 21, 1895

To the Editor —Mr Luther F McKinney, United States Minister in Bogota, writes me (Oct 17, 1895) "I enclose an article written by Dr Putnam of this city, in which I know you will be interested Dr Putnam has taken a great interest in the subject of leprosy and, as you will see, believes in the theory that the disease can be cured by the injection of the blood of an animal previously inoculated with the serum from the blood of a leprous patient He has one patient, a woman here in Bogota, whom he has been treating in this way for about four months When she began there was an entire loss of sensibility of the arms and lower limbs, and large leprous blotches or sores on her arm She has entirely recovered the sensibility of the arms, but not of the lower limbs, the blotches on her arms have entirely disappeared, so says the Doctor There are ten physicians here who are watching the case with great interest and have great hopes that extraordinary results will be obtained The great trouble here is that there is no laboratory for the proper preparation of the serum, and the lack of proper apparatus for the carrying on of the experiments very greatly retards the investigations To show how the medical profession is hampered in their efforts to stay this foul disease, some time ago Dr Putnam wrote a letter to the President of the Republic, explaining to him his theory and saying that he proposed to carry on the work and visit every part of the country where leprosy existed, and called the attention of the Executive to the assistance rendered by other civilized governments in the development of the scientific study of these diseases, and suggested that the Government provide a laboratory for the purpose of assisting in the work The President instructed the Minister of Education to answer the letter, and say that while he thought the purpose of the Doctor was good, it was a matter of personal interest, and the Government did not desire to have anything to do with it And this while there are 27,000 lepers in the country, and the Minister who answered the letter lost his wife by the disease, and has two leprous daughters in his home at the present time In about a month Dr Putnam will visit the hospital again, and he says the first leper who dies while there, he will get a portion of the skin, muscle, liver and brain and send them to you"

The article which Mr McKinney enclosed to me is entitled "Sero-Therapy," and was published in the *Herald* of Bogota, Oct 10, 1895 In it he makes a report of a medical visit to the Lazaretto of Aqua de Dios, and the sero-therapeutic medication which he has begun there in a formal manner in the treatment of leprosy He refers to an official offer, made by him on the 22d of last May, to carry on the project of establishing sero-therapy in Colombia He had already begun this treatment on some private leper patient before going to Aqua de Dios He refers to a grand lecture given by Dr Juan de Dios Carrasquilla, in the Policlinic of Bogota, the 1st of last July, on this subject This lecture has guided him in his experiments, and Dr Juan de Dios Carrasquilla will be his consultant in future At Aqua de Dios he obtained a leprous serum to be inoculated in several animals in a manner advised by Professor Ricket in syphilis, and which consists in taking some blood from the patient, inoculating the animal and returning from the animal to the patient "In one word," says he, "to make the cultivation of the leper bacillus in the blood of an animal, instead of making it in a special apparatus for the purpose of strengthening natural immunity in the animal, for the experimental infection" He visited the hospital with the Rev Father Crippa Salesiano, who has devoted himself to the patients, and Dr Luis L Gaitán, physician of the Lazaretto, and selected an adult of 16 years, in whom tubercular lepra was in full development He took from his arm 250 grammes, into an aseptic bladder, and put the latter carefully away, leaving the blood in repose for four hours during which he prepared the animals for the inoculation There were two asses and three she-goats At the expiration of the four hours he separated the serum and inoculated a certain quantity into the animals These animals were to be kept under supervision for several days With the blood serum of these animals he intended to inoculate thirty or forty patients early in November

Mr McKinney encloses me the reply received by Dr Putnam to his application to the Colombian Government

"REPUBLIC OF COLOMBIA, OFFICE OF SECRETARY OF THE GOVERNMENT No 2540

BOGOTA, Oct 17, 1895

DR CARLOS E PUTNAM—

Sir Regarding your report with respect to the installation of the sero therapy in the Lazaretto of Aqua de Dios, I have to answer that the Government, reiterating to you its manifestions of approbation and very much interest in the success of the experiments which you have undertaken with so much devotion, will give to you all the moral support necessary, so that you may not be discouraged for continuing such a praiseworthy enterprise"

Dr Putnam writes me 'We have 27,000 lepers! We do nothing for them! The acting Government pays no attention at all! We are lost!"

"Think of offering a starving man moral support," says Mr McKinney "Unless the Government takes the matter in hand the country is lost indeed Forty years ago there were 400 lepers in Colombia, now there are more than 27,000 How many at this rate of increase will there be in forty years from now?"

ALBERT L ASHMEAD, M D
270 W 43d Street

From the Shepherd Magnes

Chicago, Nov 28, 1890

To the Editor —To settle a dispute, will you kindly give us the origin of the term magnet as applied to the lodestone or magnetized iron Truly yours,

A Medical Student

Answer It is said by Nicander (according to Pliny) that a certain shepherd, named Magnes, when taking his flocks to pasture upon Mt Ida, found in a certain spot that the nails of his shoes and the iron ferule of his staff adhered to the ground After the announcement of the discovery the lodestone was called the Magnet

PUBLIC HEALTH

Bacteria in Ice —The dangers incident to the consumption of ice obtained from polluted sources, as lakes or ponds re ceiving sewage, have been much insisted on, and not only have actual instances of the communication of enteric fever in this manner been quoted, but the bacteriologic examina tion of different samples of melted ice have been adduced to show that the process of freezing has no influence on the number or vitality of the microbes Ice water, for example, from the Spree, has been found to contain 1,700 to the c cm, and from the Lake of Geneva 210, while melted hailstones yielded 72 But the recent experiments of Professor Christomanor of Athens, go some way toward justifying the old and popular belief in the purifying action of congelation, which, as he shows, effects a partial separation of all impurities, concentrating them in the inner portion of the mass Examining blocks of artificial ice from a factory supplied by a well, and others of water from the aqueduct of Hadrian, he observed in all a central core, forming about a fourth part of the entire volume, and, in its whitish, dull, somewhat granular appearance contrasting strongly with the perfect and colorless transparency of the surrounding ice While the original water from the aqueduct contained 30 milligrams of "organic matter" (solids lost in ignition?) in the litre, that from the clear ice showed only 2 8, while the turbid central *portion gave* 105.5 So with the water from the well, the 64 milligrams in which were divided in the ice into 5 5 and 202 milligrams per litre respectively It is remarkable that, though the *one* water was charged with organic or presumably organic, impurities to the extent of more than twice as much as the other, the relative proportions in which these were distributed in the ice were practically identical, being respectively as 9.3 and 351 6, and 8 6 and 311.8 to 100 *parts, or* roughly, 1-11 of, and 3 to 3½ times the impurity of the water —*British Medical Journal*

Sanitary Hints for Travelers to Venice and the Adriatic —A medical contributor to the European edition of the *New York Herald*, writes upon the above subject, *from a personal* and repeated experience as a sojourner at Venice He points out, in the first place, that the rate of mortality in that city in 1894 was 22 3 per 1000, making about the twentieth in the list of healthful great cities He also gives the following sanitary data for the use of visitors

"The stranger on arriving in Venice must take certain precautions In winter one must protect oneself from dampness, go out little in the evening, wear flannel, take long walks and beware of the poetical gondola In summer care must be taken not to catch cold while listening to the music on the Piazza San Marco, an overcoat should always be carried on the arm In the restaurants travelers should not allow themselves to be tempted by oysters or shellfish which so often occasion very disagreeable cases of enteritis, under no pretext should *any* ice be used *in the* drinking water, which should only be cooled exteriorly These last two pieces of advice are absolutely essential, their non observance is one of the chief causes *of the* gastro intestinal disorders that occur in Venice during the hot weather This year, during the intense heat of September, the number of such cases was very high, whereas it would have been very easy to avoid them by regulating the diet more sensibly

"The city, so *wonderful* in light, art and history, which still carries proudly its ancient title of Queen of the Adriatic, has a strange attraction *for every one* who has *once* put foot in her streets When one has once been to Venice one goes again, and each time one returns something new, something not yet seen, seizes your attention and fascinates you like a dream that one suspects of being reality

"The absence of dust in the atmosphere of Venice, its pavements in large flagstones, the saline dampness of the air, and the high atmospheric pressure form an excellent group of conditions for lessening the spread of consumption, and in the statistical tables that were furnished to me I remarked that the death rate from pulmonary phthisis was relatively very low Thus on an average there is in Venice *only one death from consumption per ten*, whereas *in* Paris the proportion is double—two in ten This is a very interesting fact which may lead us to send to Venice, possibly not *chronic cases of phthisis, but persons with a predisposition* for the disease and in danger of picking up contagion It is evident that in sending a consumptive to Venice it would not do to choose a torpid case, but patients that are nervous, anemic and excitable ,

"A splendid aqueduct, built about ten years ago, brings to the city a supply of spring water from the mountain Since that date the sick rate from typhoid fever has considerably diminished, and gastric fever, formerly so common, is now much rarer, and since it also now assumes a far less serious character it is much easier to cure Great care must be taken not to drink well water which is always more or less contaminated by infiltration and which must contain microbes or impure elements which were probably not without their influence on the bad reputation the city used to have from a sanitary standpoint

' In Venice apartments on the upper stories of the houses are certainly healthier than those on the lower, which, strange to say, are always more eagerly sought after It is, perhaps, better form to live on the first floor, but it is healthier on the second or even on the third The Venetians themselves are quite alive to this fact, as in the old palaces the finest apartments are on the first floor which is raised as high as possible by an entresol"

Health Reports —The following health reports have been received by the Supervising Surgeon-General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Louisiana New Orleans, November 16 to 23, 9 cases, 2 deaths

Michigan Detroit, Rochester and Three Rivers, November 16 to 23, smallpox reported present

Missouri Charleston, November 23, smallpox reported present

Pennsylvania Philadelphia, November 16 to 23, 3 cases, 2 deaths

SMALLPOX—FOREIGN

Antwerp October 26 to November 2, 1 case, 1 death

Buda-Pesth November 4 to 11, 1 case

Cairo October 29 to November 4, 1 death

Dublin November 9 to 16 2 deaths

Madrid November 5 to 12 13 deaths

Manchester November 2 to 9 2 cases

Montevideo October 19 to 26, 6 cases, 1 death

Naples November 2 to 9, 1 case, 1 death

Odessa November 2 to 9, 5 cases

Rotterdam November 9 to 16, 1 case, 1 death

CHOLERA—FOREIGN

Egypt To November 15, 759 cases, 604 deaths

Hong Kong September 14 to 21, 3 deaths

Osaka and Hiogo October 19 to 26, 3 cases, 1 death

YELLOW FEVER—FOREIGN

Cienfuegos November 17 to 24, 2 deaths

San Juan, Porto Rico October 12 to November 2, 31 cases, 8 deaths

Santiago de Cuba November 16 to 23, 20 deaths

Vera Cruz November 14 to 21, 2 deaths

NECROLOGY

Elman H Borst, M D, of Newburgh, N Y, died Nov 8, 1895 He was graduated from the College of Physicians and Surgeons, N Y, in 1889 At the time of the West Shore wreck at Newburgh in 1893, as surgeon *in* charge of St Luke's Hospital, he rendered very efficient service He was a *native* of Cobbleskill, N Y, born there thirty-two years ago, the son of Susan Vrooman and Isaac Borst The cause of his death was pneumonia, consequent upon typho-malarial fever

Wm Starbuck Mayo, M D, of New York city, and member of the University, the Authors' and Century Clubs, traveler, literateur, and toward the close of his life somewhat of an inventor, was born in Ogdensburg, N Y, April 20, 1812, and died in New York, Nov 22, 1895 He was a descendant from the Rev John Mayo of an ancient English family, who came to New England in 1630 and became the first pastor of the South Church at Boston On his mother's side Dr Mayo belonged to the Starbuck family who were among the earliest settlers of Nantucket Having graduated from the College of Physicians and Surgeons, N Y, in 1832, he at once entered upon the practice of his profession in New York, the while profiting much by hospital studies, but eventually set out to make a tour of exploration to the interior of Africa He was obliged, however, to limit it to the Barbary States, and after an excursion in Spain to return home Beside contributions to magazines and newspapers, he published "Flood and Field, or Tales of Battles on Sea and Land" (1844), "Kaloola, or Journeyings to the Djebel," "Kumri" (1849), "The Berber or the Mountaineer of the Atlas" (1850), "Romance Dust from Historic Placer" (1851), and "Never Again" (1873) He wrote dramatically, and his pages are crowded with incidents

Benjamin Cushing, M D, of Boston, Mass, who died October 16, was a man ripe in years, honors and esteem of his community He was in his seventy-third year, and had been nearly a half century in his profession He was a Harvard graduate in arts in 1842, and medicine in 1846 The *Boston Medical Journal* contains the following tribute to his worth

"The exalted character of Dr Cushing, his integrity, his sincerity, his desire not only to make his own life useful but to aid others in making their lives more useful, his devotion to his profession, his great abilities, his kindness and benevolent and sympathetic nature had endeared him to all hearts He has ended a useful life He has ministered to many His name is cherished by all Younger men in the profession owe to him a debt of gratitude that can only be repaid by imitating the example he set them, and by practising medicine along the lines of high and ennobling virtue and devotion to right principles that he taught in all his councils, and illustrated and examplified in his life They will have to remember forever his valuable suggestions, his ever-ready sympathy and assistance, his universal and respectful recognition of their merits everywhere and at all times We, to whom it was given to avail ourselves in every emergeney, without dread of intrusion, of his extended experience, his great wisdom and his wonderful skill, know, perhaps, better than others can know, that the community has sustained a loss that is only saved from being irreparable by the influence that he has exerted in raising the standard of professional attainment, manliness and true nobility, in his neighborhood, to a level with his own"

Cary B Blackburn, M D, of Louisville, Ky, December 4, of acute pneumonia He was born in Woodford County, Ky, and studied medicine under the late Prof S D Gross He served with distinction during the civil war, and in 1868 removed to Louisville, where he has since resided He was a prominent politician, having served for fifteen years as a member of the City Council

Milton R Cook, M D, of Ashtabula, O, one of the oldest practitioners of the county, died in jail where he was confined pending trial upon the charge of performing a criminal operation

J F Shepherd, M D, of Owensville, Ohio, while out driving, was thrown from his buggy and almost instantly killed by breaking his neck

MISCELLANY

Congress of Surgery of France—The next Congress of Surgery of France will be held in Paris in 1896 Professor Terrier has been named as President, M Gross, of Nancy, Vice-President, MM Bandoin, Coudray, Mauclaire and Rebland as Secretaries

Prof A C Cotton.—At a recent meeting of the Société Francaise d' Hygiène, Dr A C Cotton, City Physician of Chicago, was elected a foreign associate member of the Society

An Auction of Gems for Charity—An auction of jewelry took place in New York City, on November 19, for the benefit of the Children's Grounds—to include a play-house and playgrounds at Fairmount Park, Philadelphia The first day's sale netted not less than $50,000, and it is stated that the sale was unique as including gems of a value that had never before been offered for sale under the hammer The gems were originally the property of the late Miss Sarah A Smith, of Philadelphia

Dr J L W Thudicum, an eminent chemist of London, has printed a book called "The Spirit of Cookery" designed especially to meet the requirements of medical men The book purports to show the ethical and medical bearings of the culinary art, to contain a dictionary of culinary terms, as well as a system of general rules which will enable those who thoroughly master them to perform the principal culinary operations without reference to the frequently unintelligible records of the details of mere empiricism

Humane Police Club—Somebody has invented a policeman's club which has a rubber envelope and a wood core Messieurs the thugs, will be pleased to know that when this humane club is *once* in the hands of our guardians of the peace, there will be no more cracked skulls The near approach of the millenium is thus foreshadowed As usual, we learn that the new esthetic weapon has been tried upon a dog. His dogship, naturally enough, on regaining his canine wits, wagged his tail and in his own way expressed his pleasure in having been knocked out in so pleasant and altogether humane a way

A Fortune in a Book.—The custom of placing paper money between the leaves of a book for safety, particularly in books which are not likely to attract much attention, and forgetting all about it, was exemplified the other day when a Turin physician came upon a treasure of 40,000 lire The physician had to refer to a book upon clinics, which was in a bookcase in a library belonging to the family of Dr Giordano, who has been dead some two years This wonderful book contained some Italian rentes and a receipt for a deposit at the Banca d'Italia, altogether of the value of the above named sum The papers were, of course, handed over to the family of the late doctor

"Toxin A Novel"—The novel writer, Ouida, has adopted the above sensational title for her last book According to the review writer in the *New York Times*, the author takes pains to demonstrate, at least as clearly as she has done before, that she deserves to be classed with the degenerates He says further, "The characters in the book do things and say things that make us wonder and admire, and they love with mighty passion and hate with equal force In order to be in touch with the 'degenerates' of whom she is surely an early and conspicuous example, Ouida here enters into some particulars about disease which sensitive readers could spare The man with cancer of the food and air passages, and the details of the case of diphtheria are repulsive

The Medical Situation in Persia.—A young Persian, Dr Malik Yonan, an assistant at the Mission Hospital at Oormiah, in Western Persia, has written the following facts for the *Christian Herald* In Persia, the greatest need exists for medical missions It is said there are ten million inhabitants without a physician's care or attendance No hospitals or charitable institutions can be found outside of mission bounds, and thousands of the sick and poor are turned into the streets to die without help or remedy Some of the natives' attempts to bring relief are futile, especially so among the Mohammedan families For example, a priest will write a few words from the Koran on a slip of paper, and will dip the paper in water, and give it to the patient to taste (a hundredth solution of truth!) The two mission hospitals in Oormiah are doing an immense amount of good, and are crowded with patients from near and far, some coming from the distant Kurdistan Mountains The Mohammedan women say they are next to heaven and the wild Koords receive kind attention and treatment, and learn that the religion of the missionaries is far different and nobler than their own No branch of missionary work represents or accomplishes such a systematic amount of good and mercy as medicine

Another Hospital for the Insane in Illinois —Having hospitals for the insane for all other points of the compass, the Illinois Legislature, at its last regular session, established a new one to be called "the Illinois Western Hospital for the Insane," $100,000 was appropriated to purchase a site in that part of the State, north or west of the Illinois river, to pay for the construction of fireproof buildings to accommodate the patients with all necessary apparatus and furnishings, and to maintain it until the appropriations of the next General Assembly are available The government of the hospital is to be vested in three trustees, not more than two of whom shall be from the same political party, their terms to be six years each, and their appointment made by the Governor and confirmed by the Senate They are to appoint a superintendent who can be removed by them at pleasure under whom shall be the direct management and control of the hospital He must be a graduate in medicine and surgery from some reputable medical college and of acknowledged skill in his profession And he, in turn, is to appoint a competent assistant physician who is a graduate of some legally incorporated medical college, to perform such medical duties in and about the care and treatment of the insane as the superintendent shall direct

A Young Medical Explorer of Africa —Dr A Donaldson Smith, a graduate in medicine of the University of Pennsylvania in the year 1889, has been temporarily lost to his friends in the wilds of Eastern Equatorial Africa On November 6, he had reached Aden on the Red Sea, on his way homeward bound He had not been heard from for a period of eighteen months, and no little anxiety had been felt by those interested in the expedition for the past few months Dr Smith entered Africa on the eastern coast a year ago last June, to push across the country of the Gallas and Masai to two lakes which have been recently discovered by another expedition, then on to the Victoria and Albert, his object being to carry out and complete the line of exploration from the lakes to the east coast, a distance of several hundred miles Dr Smith was accompanied by about one hundred and fifty Africans, and at first by an Englishman, who was subsequently obliged to return to London Dr Smith sent back some fine specimens of the flora of the region after he had been on his expedition a few months, for the Geographical Society of Great Britain, and some months later was reported to be pushing on, by another party whom he had met Aside from these evidences of his safety, there were none until the arrival of his recent cablegram, as the region which he has traversed is at the present time represented by a blank space on the map

Color Photography —The *Chemist and Druggist*, London, in commenting upon Professor Joly's modification of the heliochromatic method of photography, remarks that there is need for more attention to the chemic side of color photography It also adds "We are, therefore glad to observe from *Nature* that Otto Wiener is working at the subject in this direction, his object being the direct production of color by the influence of light upon certain chemic substances He has studied Lippman's method in contrast with the old processes of Becquerel, Seebeck and Poitevin In Seebeck and Poitevin's silver chlorids are used and the colors produced are body colors in these two cases The production of these body colors is a very mysterious process, but Wiener hopes that there will eventually be found a satisfactory solution of the problem To account for the production of the colors, he advances a remarkable theory which has a well-known analogy in comparative physiology Given a collection of compounds of silver chlorid and subchlorid of indefinite proportions, such as those which Mr Carey Lea calls by the collective name of 'photo chlorid,' we must suppose according to the modern kinetic theories, that they are undergoing a rapid series of successive modifications When the red combination happens to be exposed to red light, it reflects it without absorption, and will therefore no longer be affected or changed by it Similarly for the other cases This is another process of 'adaptation' The author describes some experiments which prove that this is the true explanation and points out the importance of this view, not only for color photography but for the production of colors in the animal world It is evident that Wiener is on the right track, and if others take up the matter in this way, some of us may yet see a true color photograph"

Regulation of Maternity Hospitals in Connecticut —No person shall keep a maternity hospital, or lying-in place, it was enacted at the last session of the General Assembly of Connecticut, unless such person has previously obtained a license therefor, duly issued by the mayor, or board of health of the city, or health officer of the town wherein such maternity hospital or lying-in place is situate Within six hours after the departure, removal or withdrawal of any child born at such maternity hospital, or lying-in place, the keeper thereof shall make a record of such departure, removal or withdrawal of such child, and the names and residences of the persons who took such child, and whatever disposition of such child or its body is made, and the place where it is taken and left, which record shall be produced by the keeper or licensee of said hospital, or lying-in place, for inspection by and upon the demand of any person authorized so to do by the mayor or board of health or health officer of the city or town in which such hospital or lying in place is located No keeper of any such hospital, or lying-in place, or any of his servants or agents, shall refuse permission to any person so authorized to make such inspection, to enter such hospital or lying-in place for the purpose of such inspection, and shall permit such person so authorized to inspect such hospital and all its appurtenances for the purpose of detecting any improper treatment of such child Every person so authorized may take and remove any article which he thinks presents evidence of any crime being committed therein, and deliver the same to the coroner of the county to be disposed of according to law The penalty for a violation of this act is a fine of not less than fifty nor more than five hundred dollars, or imprisonment not more than one year or both

Practical Notes

Treatment of Hiccough —In the treatment of hiccough M Matthieu proposes the following Let the patient breathe rapidly, deeply and regularly forty-five to fifty times a minute In many cases he was able to arrest the violent crises —*Journal de Médicine et de Chirurgie*, Nov 10, 1895

Evacuation of the Biliary Calculi by the Stomach —At a recent meeting of the *Société Médicale des Hôpitaux*, of Paris, M Hayem reported the history of a patient attacked with repeated vomiting, which resembled that found in pyloric stricture Under lavage, many times repeated, thirty-eight biliary caluli were recovered The patient recovered, but M Hayem was of opinion that a direct communication existed between the gall bladder and the stomach —*Journal de Médicine et de Chirurgie*, Nov 10, 1895

Treatment of Acne —According to the *Annals de Dermatologie* Bœck, finding that Dauphin oil (*Delphinium staphisagria*, 'stavesacre") inhibited the growth of bacteria in the skin, sought to utilize that property in the following formula for the treatment of Acne

℞	Camphoræ	80
	Acid Salicylici	50
	Sulphuris precipitatæ	10
	Zinci Oxidi	2
	Saponis	1
	Ol Dauphin	12

M Make one application each night, wash the face in the morning with soap and warm water The camphor in this mixture is for the purpose of masking the disagreeable odor of the oil —*Jour de Méd et de Chirurgie, Nov 10, 1895*

Sun Glass as a Cautery —Dr Shepherd, in the *Yale Medical Journal* for December, 1895, in an interesting article on "The Sun Glass as a Surgical Instrument," recommends the sun glass for the removal of growths where it is very desirable that no scar should be left and no contracting of tissue, as upon the face and eyelids In his opinion it is simpler than electrolysis, and less likely to leave any scar, for the reason that the electric needle usually pierces the skin, and the caustic action takes place from underneath the growth or disease He uses cocain before applying the glasses, and from his experience in the treatment of nevi, and the like, he is inclined to recommend its use in such cases

Treatment of Cholelithiasis —During the meeting of the Medical Society of Virginia held Sept 3 to 5, 1895, Dr Geo Ben Johnston read a paper on the Treatment of Cholelithiasis Dr J McF Gaston, of Atlanta, was present and took part in the discussion of the paper In the course of his remarks, he paid Dr Davis, of Alabama, a just compliment for his investigations Dr Gaston said

"That while the reader claimed only to present some points for discussion, he had occupied most of the ground ordinarily taken up by those familiar with gall bladder surgery There were, however, some matters not usually dwelt upon by writers, to which attention might be directed The first and most important consideration pertains to the treatment of cases in which there are gall stones in the gall-bladder and ducts, which call for removal by incision, and it is found impracticable to attach the sac of the gall bladder to the skin or the intestines, or to suture the wall of the duct In these cases it has been proposed to tampon the intervening space to the external opening with gauze, with or without medication By packing around with the gauze, and leaving the ends of the strips protruding, drainage is accomplished, and the bile or other discharge is kept from entering the peritoneal cavity While fresh bile is not found to be an irritant to the peritoneum, the vitiated discharge which takes place after obstruction proves hurtful, and should not be allowed to enter the abdominal cavity

"Dr W E B Davis has taken a prominent part in urging this mode of procedure, and has made numerous experiments upon inferior animals illustrating the advantage of introducing iodoform gauze into the wound for the purpose of walling off the intestines and other viscera, while it serves, by capillary attraction, to carry off the discharge

"This has been practiced by others with the best results, and to Dr Davis is due the credit of impressing upon the profession the advantages of this treatment in cases not admitting of the attachment of the gall-bladder to the external opening or the intestines, and in which it is found impracticable to close by suture an incision of the common duct after the removal of biliary calculi"—*Alabama Medical and Surgical Age*

Society Notes

Lackawanna County (Pa), Medical Society —The following resolutions were submitted by Dr J C Bateson and adopted by the Lackawanna County Medical Society, in the city of Scranton, Pa, Nov 12, 1895

Whereas, There is a widespread and growing practice on the part of manufacturing chemists and pharmaceutical companies to put up their products in original packages covered with advertising matter giving name, dose, by whom made, and a wide range of indications for use, so that the physician finds it most convenient or necessary to prescribe in this form and thereby unwillingly injure his own business, and

Whereas, Many of these manufacturers publish cheap journals for advertising purposes, thereby infringing on the domain of regular medical publications, having the effrontery even to ask physicians to pay them for advertising their own goods, therefore,

Resolved 1 That the Lackawanna County Medical Society disapproves of such methods and devices to introduce remedies and journals

2 That for mutual protection the medical fraternity is advised not to prescribe medicines put up in the manner indicated

3 That the State and County societies, together with regular medical journals, are invited to unite against these cunning schemes

The annual meeting of the County Medical Society was held in New York November 25 The following officers were elected for the ensuing year President, E D Fisher, First Vice-President, F Peterson, Second Vice-President, J H Fructnight, Secretary, Charles H Avery, Treasurer, J S Warren——The monthly meeting of the Ramsey County, Minn, Medical Society was held in St Paul November 25

Congress of American Physicians and Surgeons —At a meeting of the Executive Committee of the Congress of American Physicians and Surgeons, held in New York City November 23, the following officers were elected

President of the Congress, Dr Wm H Welch, Baltimore, Md, Secretary of the Congress, Dr Wm H Carmalt, New Haven, Conn, Treasurer of the Congress, Dr Newton M Shaffer, New York City, Chairman of the Executive Committee, Dr Landon Carter Gray, New York City, Secretary of the Executive Committee, Dr Wm K Simpson, New York City

The next Congress will meet at Washington, D C, in May, 1897

Hospital Notes

St Luke's Hospital, New York —The thirty-seventh annual report of this institution has been published, covering the twelve months ending St Luke's Day, Oct 18, 1895 The volume of 110 pages is largely devoted to the medical and surgical service tables The report shows that the new hospital is so far advanced that, within a few months, the buildings will be ready for occupancy The work of the training school for nurses has gone on steadily, notwithstanding the fact that the service within the hospital has been cut down one half The Board of Managers have in view the amplification of the pathological work of their plant by the construction of a building, for the endowment of which the sum of $200,000 is to be raised The approximate per diem cost was $1 61 for each ward patient, while the price charged paying patients has been only $7 00 per week

The Newport, R I, Hospital —Mrs F W Vanderbilt has added $5,000 to her previous contribution for the new operating building attached to the Newport Hospital, which makes her gifts for this purpose $8,000 in all, and practically pays in full for this building

Presbyterian Hospital Benefit —The managers of the Presbyterian Hospital of Chicago have reason to congratulate themselves on the concert given at the Auditorium on the evening of December 2 The Theodore Thomas Orchestra, the divine Melba, and the magnificent Scalchi, made up an entertainment which will long be remembered in the medical history of Chicago The vast Auditorium was crowded and the box office turned in a very handsome revenue to the support of the hospital

The Medical Staff of the Erie County Hospital, at Buffalo, N Y, has submitted its second annual report to the superiors The report shows that during the year from Oct 1, 1894, until Sept 30, 1895, the members of the staff made 1,335 visits to the hospital and 2,452 patients were treated——The Sisters of the Poor of St Francis, having charge of St Mary's Hospital at Hoboken, N J, will build a large addition on the south side of the hospital in order to meet the demands for more accommodations

Detroit Notes

Dr Hedley Williamson read a paper on "Smallpox" before the Detroit Medical and Library Association at their meeting of Nov 25 This society has issued a monthly card giving the names of the authors and the title of their papers for each Monday evening of December, and it is the most complete card that the society has issued for some time, the last day, December 30 being assigned to George Henry Fox, M D, of New York

Deaconess Hospital —At a meeting of the staff of the Deaconess Hospital the following officers were elected, and the different positions assigned as noted Staff of Deaconess Hospital President, E B Smith, M D, Vice-President, G A Kirker, M D, Secretary, J F McPherson, M D, Consulting Surgeons, D Maclean, M D, H O Walker, M D, A W Ferguson, M D, of Chicago, Attending Surgeon and Operative Gynecologist, E B Smith, M D, Consulting Physicians, P Klein, M D, G A Kirker, MD, C Brumme, M D, Attending Physicians, L C Newton, M D, T M Lawton, M D, Consulting Oculist and Aurist, C E Frothingham, M D, Attending Oculist and Aurist, L E Maire, M D, Gynecologist and Obstetrician, J F McPherson, M D, Consulting

Gynecologists and Obstetricians, C H Leonard M D, N W Webber, M D, E W Jenks, M D, Consulting Neurologist, J E Emerson, M D, Attending Neurologist, T J Parker, M D, Physician for Throat, Nose and Chest M McColl, M D, Assistant Physician, J H Greenwood, M D, Physician for Children's Diseases J F Bennett M D E W Tonkin, M D, Bacteriologist and Pathologist Board of Directors, Officers of the Staff ex officio, L L Maire M D, T J Parker M D

Health Office report for week ending Nov 29, 1895 Deaths, under 5 years, 32 total, 87 Births, male, 45, female 50, total, 95 Contagious diseases diphtheria, last report, 34 new cases, 29, recovered 17, died 8, now sick 38 Scarlet Fever Last report, 15, new cases 8, recovered 4, died none, now sick 19 Smallpox Last report 2 new cases none, recovered none, died none, now sick 2, 1 from Hamtramack and 1 from Detroit

St Louis Notes

Weekly Report of Health Officer —Total number of deaths during the week ending November 30, 170, during the preceeding week, 160, during the corresponding period of last year, 158 Births reported, 211 Contagious diseases reported during the week ending November 30 Diphtheria, 115 cases, 18 deaths, croup, 16 cases, 8 deaths, scarlatina, 8 cases, measles, 8 cases

The St Louis Medical Society —At the regular meeting Saturday evening, November 30, the scientific program consisted of a paper by Dr Warren B Outten on "Hematomyelia" with an extended discussion by neurologists and surgeons The paper was an elaborate examination of the subject based upon a collection of opinions expressed by leading neurological authorities in literature, and upon the personal experience of the leading neurologists of America The deduction made was to the effect that primary and isolated hemorrhage into the substance of the spinal cord does not occur as a result of trauma, that cases where hemorrhage of that character are found are to be explained as the secondary complication of an antecedent change in the cord, rather than as the direct result of injury The paper was a valuable one for the fact that it clearly demonstrated the uncertainty that prevails among observers with regard to the pathology, diagnosis, and prognosis of hematomyelia as an isolated condition Whether the conclusion drawn is warranted is questionable Certainly, as was pointed out in the discussion, the demonstration of one case of isolated primary hematomyelia by careful post-mortem would at once decide the question of the occurrence of it, no matter what past experience had been It does not decide the question of possibility in such a matter as this to cite opinion or even past experience, the most such a reviewer can do is to emphasize the improbability of hematomyelia being the lesion in a given case of trauma open only to clinical observation

Smallpox is reported from Charleston, Mo, where four cases have occurred

The Hospital Saturday and Sunday Association —Returns are not yet in covering the collections for November 30 and December 1, but the partial reports show a gratifying prospect In 1894 the contributions amounted to $9,992 17, which was distributed among nine hospitals in sums proportioned to the number of free patients treated during the year

Louisville Notes

Louisville Medical College —The class of 1896 of the Louisville Medical College elected its officers at a meeting held in the college building last week Sixty seven members were present The following were elected President, E R Morris, North Carolina, Vice-President, J W Benham, Indiana, Secretary, O K Harris, Indiana, Treasurer, R E Egan, West Virginia, Salutatorian, J C Lawrence, Virginia, Valedictorian, E B Hardin, Kentucky The valedictorian was the only Kentuckian on the list He is a relative of P W Hardin, the recent democratic candidate for governor

Insane Asylums—Dr J H Letcher, of Henderson, a prominent Republican, is mentioned as the choice of Governor-elect Bradley for Superintendent of the Hopkinsville Asylum, and Dr L N Baughman, of Flat Lick, for Superintendent of the Eastern Asylum at Lexington Dr Baughman has held public office before, having been pension examiner under the last Republican president

Health Ordinance —At the last meeting of the General Council the Board of Public Safety presented the ordinance prepared by Dr White looking to the prevention of diphtheria scarlet fever and smallpox For some weeks several public spirited ladies have been submitting cards to the local papers, crying out for compulsory immunization of all children attending the city schools from diphtheria, and they were answered by a letter to the editor of the *Times*, calling attention to the great importance of obtaining the passage of the contagious disease ordinance Since then the ordinance has been submitted as above reported, and it is to be hoped that the Health Committee will be importuned by every public spirited person to recommend its passage, and the Council to vote favorably upon it The Mayor's signature will be affixed if it is passed

Death Rate —The report of the health officer for November, 1895, shows a less number of deaths than in the corresponding month last year In November, 1894, there were 256 deaths, and in the month just past 249 During the month consumption caused 17 deaths, diphtheria, 14, typhoid fever, 11, cerebral meningitis, 11, old age, 10, pneumonia, 29, there were 17 still births One hundred and thirty-three females and 130 males were born in Louisville Annual death rate per 1,000, 16, white—168,547 population—death rate, 14, colored—36,453 population—death rate, 22, for the month, white, 1 4, for the month, colored, 1 4 There were 66 deaths during the last week in November

Cincinnati Notes

The Mortality report for the week ending November 29, shows the following Diphtheria 5, entero-colitis 2, scarlet fever 1 typhoid fever 3, whooping cough 1, other zymotic diseases 5, cancer 3, phthisis pulmonitis 7, other constitutional diseases 2, apoplexy, 2 Bright's disease 2, bronchitis 7, gastritis 2, heart disease 5, meningitis 3, peritonitis 3, pneumonia 12, other local diseases 29, developmental diseases 8 violence 3, under 5 years, 26, total 104 Annual rate per 1,000, 16 09, preceding week 98 Corresponding week in 1894 112

Dr Wm Osler, of Baltimore, delivered an address before the Academy of Medicine November 19, taking for his subject "Higher Medical Education" Dr Osler made a strong plea for more general interest on the part of the public and especially in the establishment of college laboratories, to which he thought the wealthy men could not make a better disposition of their money than by endowing them—this in view of the great work they are doing for humanity's sake Dr Osler was entertained by Col Chas W Wooley

The Home for Incurables has just received an endowment of $1,000 from the estate of David Eckstein, which was left to a charity to be named by the Mayor

The Ohio Wesleyan University has received a gift of $50,000 from Dr Chas E Slocum, of Defiance, Ohio for the purpose of enabling the institution to erect a fire-proof library building

The arrangements are about completed whereby the University of Cincinnati will have a completely equipped medical department

At the meeting of the Academy of Medicine held December 2, Dr E Gustav Zinke contributed a paper on "The Management of Occipito-Posterior Position" It was discussed by Drs W H Taylor and Giles Mitchell

There is less typhoid fever at present than for a number of years, although the Ohio river, which is the water supply shows but two feet and four inches

Dr F W Hendley the Superintendent of the Cincinnati Hospital, has been promoted to the position of Major and Surgeon of the First Regiment of Infantry made vacant by the resignation of Dr L C Carr

Dr J E Lowes, of Dayton, has been appointed Surgeon-General of Ohio by Governor Bushnell

A new medical society has been organized in the Medical College of Ohio and named for Prof P S Conner, the eminent surgeon Dr Parley Phillips has been elected president

Two cases of favus were discovered in the Children's Home last week They were sent to the hospital

The quarantine on the Children's Home has been raised

The Laura Memorial College, which was recently furnished and presented by Alexander McDonald as a memorial to his daughter, opens with a class of forty and promises to soon become recognized among the front rank of the medical colleges for women in this country

Mrs Jane A Gibson has made a second endowment of $5,000 to Christ's Hospital

The *Tribune* has just presented a handsome buggy as a prize for the physician receiving the highest number of votes Dr S J D Meade, a 'homeopathic" practitioner was the winner, he having obtained 33,000

A case of dislocation of the fibia and tibia, forward on the femur, was admitted at the City Hospital last week as a result of a boiler explosion on a steamboat, this is the first case of this character appearing on the records

Dr W H Dougherty, of Corinth, Ky, was thrown from his buggy on the 25th of last month and sustained severe injuries

The public and Sunday schools of Zanesville, Ohio, have been ordered closed as the result of an outbreak of forty-five cases of scarlet fever

An epidemic of typhoid fever is prevailing at Randolph, Ohio, which is claimed to be due to an abandoned cemetery in which vicinity all the cases have occurred

A discussion of the humanity of vivisection by a number of the profession of Cincinnati has recently been published by the *Commercial Gazette*

Washington Notes

Weekly Report of the Health Office—The report of the Health Officer for the week ended November 23 is as follows Number of deaths (still-births not included) white, 58, colored, 35, total, 93 Death rate per 1 000 per annum, white, 16 1, colored, 20 7, total, 17 5 Death rate per 1,000 per annum for corresponding week last year, 16 8 The reports of deaths to the Health Department during the past week show a continued improvement of the general health of the city From 99 deaths reported week before last the number decreased to 93, a decline equal to 6 per cent Accordingly the annual death rate fell from 18 68 to 17 55 for the whole population The mortality from typhoid fever was 4, as against 7 in the week previous This malady is evidently on the decline During the first week of November the deaths reported therefrom numbered 17 since which time they have fallen respectively each week to 8, then 7, and now 4 The dangerous contagious diseases present no epidemic form, there having been but 1 death from diphtheria and 2 from scarlet fever The week's health history shows the decided fall in infant mortality from 35 of those under 5 years old to 18 The fatalities from chronic and acute lung troubles stand this week at about the normal, while taking whole list of diseases in view, the general condition of the public health is satisfactory

Pedestal for Dr Gross' Statue—Col Wilson, of the engineer corps, in charge of public buildings and grounds, is now engaged in the execution of a work placed in his care by a special act of Congress It is the construction of a granite pedestal for the bronze statue of Dr Samuel D Gross, which is to be erected at a prominent point in the Smithsonian Park, between the National Museum and the Army Medical Museum The pedestal will be of simple and impressive design Upon one of the faces of the die will be carved a partial leaf of palm and laurel, within which will be in raised letters the name, "Samuel D Gross," and under it in incised letters the following words "American physicians have erected this statue to commemorate the great deeds of a man who made such an impress upon American surgery that it has served to dignify American medicine" The statue is now being made abroad upon a design of a foreign artist

Medical Society of the District—At the regular weekly meeting of the society, held on the 27th inst, Dr N Jacobi, of New York, read a paper on "Nephritis in the Newly Born" Upon its conclusion the society honored him with a vote of thanks Dr Bovee presented two specimens of fibrinous uterus, removed by abdominal section Dr Stone presented a specimen of appendicitis A committee of three, consisting of Drs C H A Klinschmidt, F C Smith and Geo L Magruder, presented resolutions of regret on the death of Dr Geo C Merriam

The Secretary and Department of Public Health—At a special meeting of the District Medical Association, held on the 30th inst, the subject of a Department of Public Health, with a medical man as Secretary and member of the Cabinet, was fully discussed The matter came before the association formally by a letter from Dr Jerome Cochran, chairman of the committee on this project, appointed by the American Medical Association The President's message to the Fifty-third Congress advocating such a department, and Senator Gray's bill for its establishment, were read before the physicians present It was voted to favor the measure, and to choose a committee to coöperate with Dr Cochran in urging the passage of an organic law by the present Congress The committee named consists of Dr H L E Johnson, Dr Samuel C Busey, Dr W W Johnston, Dr J R Wellington, and Dr C H A Kleinschmidt

Committee of Board of Trade on Public Health—Mr S W Woodward, President of the Washington Board of Trade, has appointed the following named medical men on the Committee on Public Health Drs Samuel C Busey, W W Johnston and H L E Johnson

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from November 23 1895, to November 29 1895

Major George W Adair, Surgeon (Washington Bks, D C), is hereby granted leave of absence, for one month, to take effect about Dec 4 1895

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending November 30, 1895

Surgeon F Anderson, detached from the "Amphitrite," and ordered to the "Dolphin"

Surgeon P M Rixey, detached from the "Dolphin," and placed on waiting orders

Surgeon J E Gardner, detached from Port Royal Station, and ordered to the "Amphitrite"

P A Surgeon I W Kite detached from the Franklin," and ordered to the naval hospital, New York

P A Surgeon T A Berryhill, detached from the naval hospital, New York, and ordered to the Port Royal Naval Station

Change of Address

Brooks S D from Chicago, Ill, to Marine Hospital St Louis, Mo

Cobb W F, from Mona Iowa, to Lyle Minn

Fowler W S, from 59th St and Washington Av to 4142 Berkley Av, Chicago, Ill

Kaull, W M, from Tiffin to Mexico, Ohio

McLain John S, from 1624 N St N W to 1820 10th St N W, Washington, D C

Perry, T B from Fortress Monroe, Va, to Milledgeville, Ga.

Small, A R, from 8300 State St to 3180 Indiana Av Chicago, Ill

ORIGINAL ARTICLES

ON THE RELATION OF SEX TO THE PROGNOSIS OF EPILEPSY

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY WILLIAM BROWNING, M D
BROOKLYN N Y

The purpose of this paper is briefly to call attention to a difference in the sexes as regards chances of recovery from the convulsive habit This is a matter that has not been absolutely overlooked, though it seems to have received scant attention Only in Gowers have I so far found any original reference to it, and he simply says that, "the prospect of arrest is slightly better in males than in females"

It is unusual for sex to play a very important rôle in those diseases that are common to both male and female Among epileptics there is no great preponderence of one sex over the other In my former statistics (to July, 1891)[1] of this disorder there were 84 M to 66 F Reynolds found 102 M to 70 F, but says that "practically, the two sexes appear to be about equally affected" Some later statistics indicate a slight excess of females, but this is disputed And it should not be overlooked that males are more exposed than the opposite sex to accidents provocative of epilepsy At any rate in my own series the numbers of the two sexes have not varied sufficiently to account for any considerable difference in results At most this has but a relative bearing on the subject in question

It is of course true, that a great majority of epileptics are but little amenable to treatment Nevertheless this does not hold for selected cases If the trouble occurs in a young male (youth or early manhood) and is taken promptly in hand, and if the case does not show organic lesion or too many marks of degeneracy and can be followed up, there is in my experience, a considerable, perhaps an even chance of cure—taking this term in the sense of cessation of seizures for years at least after conclusion of treatment[2]

In other and less favorable cases in males, there is correspondingly less hope of cure, though it is now and then possible The relief of weak heart, ear troubles, gout, the expulsion of tape worms, etc, and sometimes more direct medication will give an occasional cure

If, now, we compare with this showing in males, the results obtained in females, we find, in my experience, one long line of failures In dispensary practice there has hardly been an exception to this[3] True, we can give some relief and occasionally think we are to effect a cure In some cases of digestive or cardiac disturbance, that have been attended by one or two seizures, evidently but symptomatic in nature, we may even see a complete cessation And the like may hold for an occasional case of so-called reflex origin But in any case in the female that could certainly be classed as epilepsy there has been no cure, and only now and then any material amelioration In private practice, the results have been but little better—the longest free period in any female patient has extended but one year

Therapeutically, not only has the same plan been tried as in the males, but also various modifications of it with the hope of better suiting the female

The same fact appears casually in the paper to be presented here by my colleague, Dr Barber He soon had to give up his trial of *solanum carolinense* in the case of females, because of its entire failure, while in the boys there has been sufficient benefit to enable him to continue observation

In view of these facts, the unsatisfactory outcome can hardly be attributed to a poor adaptation of treatment In seeking an explanation I have come across a few things having apparently some bearing thereon, though even if related or parallel matters they serve quite as much to verify as to explain

In the first place it may be recalled that any intoxication habit (for alcoholics, narcotics, or what not) is less tractable in women than in men It is, alas, little enough so in either Under institutional care this may not be apparent, but in private cases one soon has to recognize this fact

Again, my service at the Kings County Hospital includes a department of some fifty feeble-minded and idiotic children Last year a party of noble women in Brooklyn started a school for the instruction of these incapables There it was soon apparent that though the sexes were almost equally represented in the whole number of inmates of that department (twenty-six males to twenty females), the number of girls capable of any real instruction was usually about half that of the boys (thirteen males to six females at this writing) This was the more surprising, as in other mixed schools the girls are pretty uniformly found to be on an average brighter, more studious and conscientious than the boys But inquiry elicits the information that generally in schools for the mentally defective, the boys are found brighter as scholars and more amenable to training than the girls

The very kind reply of my friend, Dr M W Barr, Chief of the Pennsylvania Training School for Feeble-Minded Children at Elwyn, is well worth giving

---

[1] The Epileptic Interval etc New York, 1893

[2] In a continuous series of thirty four cases all males ranging in age from 11 to 25 years, nine were seen but once, and *hence must be* deducted. In the remaining twenty five many of the above specified conditions were not adequately filled, and yet they gave a record of six definite and five more presumptive cures

[3] In a continuous series of thirty four females covering the same period as the above series of males and with like range in ages twelve were seen but once thus leaving twenty two Among these there was but one in which there was any question of cure and even this was too uncertain to be so classed

"We find that the mental improvement is more marked in the boys than in the girls—the ratio of 3 to 2

'The physical improvement is about equal in both sexes We find that the mental condition does not always depend on the physical, nor the physical on the mental

"I do not know any explanation of this, or why the boys are more improvable than the girls, except that the girls are more nervous and less willing to do good honest work than the boys"

These matters seem to have a direct bearing, however difficult it may be to analyze closely, on the main point raised Perhaps there is some additional force in the fact that a portion of the imbecile class are also epileptics It would be interesting to know the school ratio, so to speak, of the mental cripples that are free from epilepsy

On the other hand, a comparison of the gross statistics of recovery in the insane, fails to discover any particular difference in the sexes Barring the excess of male paretics over female, the chances of recovery are about equal in the two, if we take all forms together (shown by adding up some 15,000 cases from recent asylum reports)

Any attempt to interpret these matters is little more than speculation It is, however, important to find the true explanation in the case of the epileptic, as on it must depend our treatment to be successful

(*a*) The suggestion of a "greater strain placed upon females at the age of puberty" (Hare), hardly calls for serious consideration If such an element exists it must tend rather to produce an excess of epileptics in that sex than to any essential difference in the resulting disease itself

(*b*) The influence of a possible hysterical factor is better worth attention I must acknowledge that it has often proved a difficult question to decide on its existence or not in female epileptics At one visit a case will appear a pure epilesy, and at another the hysterical features will be just as clear This is a separate matter from hystero epilepsy, although where the latter in the female proves to be more than transitory, definite epileptic symptoms soon begin to color the case

With males, on the contrary, my experience is uniformly to the effect that epilepsy and hysterical epilepsy are well separated, *i e*, a given case is wholly one or the other

But the persistent factor in female epilepsy has never been influenced by a regard, therapeutically, to a possible hysterical side, though this is only negative and weak evidence

(*c*) The power of habit in the female That this is greater than in the male may be granted But, even if this applies to acts beyond the influence of the will, it can hardly account for the lesser mental receptivity of the weak-minded female, though this latter may be an entirely separate affair

(*d*) Finally, it is possible that failure of treatment in the female epileptics depends on some inherent fundamental condition and that we can never expect to make it as successful as in males

The results of operative treatment have not been considered in this paper, partly because that applies to a special class of cases and partly because there would be too few females for a proper comparison, as well as the great uncertainty in most of the results reported

So far, we can at least recognize that, while there is a fair chance of cure in the most favorable male cases, we must expect little in the female—and remember it in prognosis

---

A CLINICAL NOTE ON THE TREATMENT OF EPILEPSY BEFORE THE HABIT IS FORMED

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association at Baltimore, Md May 7-10 1895

BY E D FERGUSON, M D

TROY N Y

Though many links in the chain which would represent the complete pathology of epilepsy are lacking, enough is known to furnish occasionally a clew to rational treatment, and whether our measures may be addressed to some etiologic factor or be symptomatic as the administration of the bromids for the control or diminution of the attacks, it seems fairly evident that in the majority of instances the longer and more frequently the seizures have been occurring the greater will be the difficulty in abolishing them or diminishing their frequency

In a general way, the influence of long continued recurrence is recognized under the name of habit, and is no doubt to be accorded some importance, for it will scarcely be necessary to adduce illustrations of the influence of habit on many of the functions of the body

Undoubtedly, in the treatment of epilepsy, more brilliant results will obtain in those cases in which the cause is ascertainable and of such a nature and so situated that it can be efficiently treated, and in particular will we be entitled to expect a successful result if the case comes under observation while still showing only the minor forms of its manifestations, but even when we are unable to direct our measures from an etiologic standpoint, and must rely upon the ordinary routine means, if the treatment be thorough and energetic, begun at an early date and continued for a long period, we may cure some cases that would prove incurable if subjected to treatment at a later date This applies to the cases subjected to any therapeutic plan, whether surgical (at any point from the vertex to the soles of the feet) or medicinal, as the usual course of the bromids In these cured cases, however, there is occasionally a lingering doubt that those presenting only the minor manifestations might fail to develop into *le haut mal*, but no one can doubt that a proportion still remains in which if *le petit mal* be relieved the patient is saved from the greater events of the disease

By way of illustration, I will cite two instances of the minor form, presumably of reflex origin, and associated with that somewhat overworked source of irritation, phimosis

The first case, a boy about 6 years of age, had for several months been noticed to act peculiarly during urination That fact was reported to me, and I requested the parents to note carefully the events occurring at that time, the report embraced the statement that he would defer the act as long as was practicable, and then, when about to accomplish it, would seem agitated as by fear, his face would become pale, he would start backward a step or two, his body would become rigid, and there appeared to be a momentary unconsciousness, but as the urine began to escape these symptoms would diminish so that at the completion of the act, or a few moments thereafter, he would be ready to resume his play or studies

It was some time before I saw the child for exammation, for in response to my inquiry as to the condition of the prepuce, by a mistake I was told that it had been examined and pronounced in a normal condition, but the symptoms becoming more pronounced and the evidence of a brief loss of consciousness becoming stronger, I insisted on seeing the child, and an examination showed a phimosis with a pinhole orifice, and at the incision I found the prepuce strongly adherent to the glands over quite a portion of the surface For two or three weeks after the incision the symptoms continued, but in a gradually diminishing degree, the diminution apparently keeping pace with an increasing confidence that the old sensations had been removed, and finally the trouble definitively ceased without the administration of drugs

The other case was that of a lad, 10 years of age, who had shown no trouble prior to seven months of age, aside from measles when five months old The first signs consisted of slight convulsive seizures, consisting mainly of rigidity of the muscles of the trunk and oscillation of the eyes, though at eight months there was some paræsis of the right side which persisted for quite a period For about eight years the attacks recurred on the average from three to six times daily, were brief in duration and were not followed by somnolence, but the frequency would be increased during the continuance of intercurrent illness During the following two years the attacks did not notably increase in frequency, but they became somewhat more severe and were followed by a stupid or drowsy state The father consulted me concerning him in an incidental way, and I advised that he should have him examined, particularly in reference to natal or post-natal injury to the head and the condition of the genital apparatus, for he described the act of urination as difficult and spasmodic In the meantime I advised the use of bromids to try and control the habit element As he lived a long distance from me, I heard nothing from the case for some months, when, being in the neighborhood of his home on another case, I again was consulted, and found a well developed boy of 10, apparently in good health in every way except the convulsive seizures, and some slight defect in the motility of the right side, presumably due to a mild attack of polio myelitis in his early infancy There were defective educational development and somewhat peculiar manners, both of which were doubtless in a measure the result of his having been kept from other children and from school

The bromids had stopped the convulsions for nearly six months, but they had begun to recur A tight and adherent prepuce furnished one ground for interference and I advised that the phimosis be removed, which was done somewhat later, and thereby he was relieved of his urinary trouble,[1] but after a time the convulsions recurred, and he will probably become a confirmed epileptic, though I am convinced that an early operation and efficient medical treatment, particularly if instituted before the epileptic habit had been formed, would have resulted in a cure

Another case of reflex influence interested me very much It occurred in the practice of a medical friend, early in my professional work and before the use of the bromids had become so common The patient, a man, had had several epileptic attacks, when, during an examination of his body for general diagnostic purposes, and while manipulating one foot a paroxysm occurred The same event having been repeated at another and not remote occasion, a more critical examination disclosed a small subcutaneous tumor on the dorsum of the foot, and pressure thereon produced a more or less complete epileptic attack Excision of this growth resulted in a definite recovery

Another instance will serve to illustrate the importance of thorough measures in the early stages of the disease A young woman consulted me on account of a single convulsive seizure which had occurred a day or two before Though realizing fully the fact that a single attack had slight diagnostic value, the description of the fit, as witnessed by a friend, led me to suspect so strongly that it was epileptic that I at once placed her on a bromid treatment with directions to make certain increase in the dose in case of a recurrence In a short time she had another attack and then another, so that she had several within a few weeks After each fit the dose of bromid was increased, until finally the intervals increased, and after about three months she had the last attack The dose of bromid of potash had then reached a little more than 2 drachms daily and was continued at that amount for upward of two years, and then gradually diminished, so that it was stopped at about four years from the commencement of the treatment This case, like the majority of cases of epilepsy, furnished no evidence as to causation or pathology and was treated entirely on an empirical basis If the attacks had been allowed to continue for quite a time it is fair to assume that the condition would have become more difficult of control and probably incurable

I am fully aware that this note contains nothing new, but it has seemed clear to me that the utility of energetic measures in the early stages of the disease has not been adequately urged or appreciated, and it is then, if at all, that we may hope to eliminate one factor, a minor one though it be, in the continuation of the disease, i e , the element of habit

---

THE LIMITATIONS OF SURGICAL OPERATIONS AS A MEANS OF RELIEF OR CURE IN EPILEPSY

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY THOMAS H MANLEY, M D
NEW YORK

During the past two decades, or the last quarter of the nineteenth century, a vast change has been wrought in the principles governing surgical operations, the use of the microscope has sapped the very foundations of pathology which was taught as late as the early 70's, and in that short space of time, we have witnessed the birth and death of many theories which were advanced with the force of dogmatic emphasis

In short, our age is one of theories and it would seem that in spite of the scientific foundation which modern medicine is supposed to rest on, our position is anything but fixed and definite, and, never, probably at any time, was the profession more eager to test the efficacy of any therapeutic agency, provided only that its source was from those recognized as authorities Our bent is essentially materialistic, and we are endeavoring to wring from nature her mysteries and her secrets by experimentation and biologic research, rather than on the old beaten track of clinical observation Surgery has made vast inroads on the domain of the physician Not content with the slow uncertain action of medicines, by an internal route, we now take time by the forelock and scarcely any recess of the body is beyond the exploratory advances of modern surgery

The same cavities which our forefathers never penetrated, except with fear and hesitation, have lately been ruthlessly invaded, and we have been led to hope that the time had come when many of the maladies heretofore quite incurable were now capable of prompt and certain eradication

Truth and justice, however, compel us to avow that, except with the cavity of the peritoneum, it remains an open question, whether or not aggressive surgery has any well founded claim in the way of securing better results than may be attained by constitutional or symptomatic treatment

With pulmonary diseases, surgery can do little, except in draining for empyema And in this, of all the cavities, physics has brought the art of diagnosis practically to perfection Since the doctrine of cerebral localization has been promulgated, Ferrier, Broca, Victor Horsley, McEwen and others have made the brain and its surgery a special study, the cranial cavity has been opened and explored in the treatment of many traumatic and pathologic conditions which, formerly, were regarded as quite beyond operative relief

From what had been achieved by the security against inflammation or septic infection which antiseptics afforded, the precision derived by cranial topography and accurate cerebral localization, together with such osteoplastic operations on the cranial walls as would permit us to again fill in the wide breach made through them, it was believed that the time had come when we might succeed in locating and removing safely, neoplastic formations, or such other pathologic conditions as give rise to or perpetuate many of those maladies which appear to be of central origin

It was earnestly hoped that at last a way had been opened by which we might offer some prospects of cure of that dreadful affliction designated epilepsy, that if it were dependent on cranial contraction, expansion and free play of the cerebral mass might be promised through a simple division of the cranial walls, if there were hard osseous compression, it would be easily relieved by the trephine, if there were new growths or adventitious formations, that their extirpation might be safely accomplished

How far our anticipations have been realized in this direction, what positive substantial progress has been made, it is interesting and necessary that we now determine, in order that we may be able to make a reasonably definite forecast of the results following these cranial operations which are undertaken to relieve a case of epilepsy, whether their scope should be enlarged, or, on the contrary, restricted to only very rare and exceptional instances in which the physical distress is so great that any description of interference, not too hazardous to life is justifiable when indications point, even though remotely, to the probable seat of trouble

Before we undertake the treatment of any disease on a scientific basis, it is indispensable that we have a correct understanding of those pathologic conditions of the elements of the structures or organs through which it finds expression Though, even when such a consummation is attainable and science has pointed unmistakably to definite etiologic factors, it has, so far, been singularly impotent in all but a very few instances to proceed any farther and indicate specific remedies Thus we will observe that though physics has enabled us to easily recognize and follow every stage of pneumonia, its mortality remains as great or even greater than when symptoms alone were treated Nor has the discovery of the microbe of phthisis suggested its antidote Our microscopic differentiation of the cell elements of malignant growths has in no manner enabled us to the more effectively abort their progress or, after their advance has begun, do more than treat them on general principles

But with epilepsy, anything like a definite pathology is wholly wanting There are good reasons for believing that though its manifestations are through explosions of nerve force, by way of the encephalon, there are other subtle influences in operation, possibly in the blood of some one of the eliminating organs While the cause of the malady remains in such profound obscurity, how is it possible to direct effective measures for its control or cure? And this view of the question is borne out by the fact that in our time nearly every large city is provided with special hospitals or asylums for the management of many of these hopeless cases

But there are quite a few of the focal or Jacksonian type, which seem to date their origin to an injury of the skull Perhaps a blow or a fall, which produced evident cerebral concussion, or a fracture with depression of bone In one case which came under my care there was a marked depression of the left glabella of the frontal bone, produced by compression of the obstetric forceps at the time of birth

For this class, aggressive surgery was looked to for relief The depressed bone might be elevated or removed, an organized blood clot pressing on the cortex might be displaced, a new growth enucleated, or adhesions between the meninges and brain substance liberated

Intra cranial surgery was soon greatly enlarged, and this offered a fertile field for radical methods Treatises have been written on it and monographs in great number have been widely circulated, setting forth the claims for this new departure Progress, however, had not made very great advance before circumstances arose that led to a pause, and then reaction set in, until now we have reached a middle ground, with a tendency rather in the direction of a salutary conservatism, than ill-timed indiscriminate operating

It was found that the operation of *trephining* itself was attended with many serious dangers to life from hemorrhage, meningitis and cerebral hernia, and what was most discouraging, after varying intervals of time, the convulsions almost invariably returned

In some few cases the epileptic attacks were not so frequent nor violent after operation as before True permanent cures have been reported, but no such result has ever come under my observation, either from the hands of others or in my own practice It is not impossible nevertheless, to find an occasional cure succeeding operation in a certain class of cases A great fright has been known to produce epilepsy as well as a severe physical accident, and, singular to say, the same agencies have been known to promptly cure it Some years ago a little girl was under my care for the treatment of a fractured arm, resulting from a fall over a rocking-horse, and though a victim of the most violent form of epilepsy before the accident, she has never had a seizure since, many have experienced a vast improvement by hypnotism, the faith cure and clairvoyant treatment It is, therefore, reasonable to inquire what role psychic influence plays in these cases which been operated on, the anticipation, dread and fear of the ordeal, the effects of the traumatism on the tissues, the loss of blood, or the effects of the anesthetics?

If we were only assured that any type depended in certain cases on localized compression, as depressed bone, or tumor pressure alone, then we might hope for enough benefit ensuing to warrant us in undertaking an operation for its removal But those who have opportunities to examine many traumatisms of the skull, know well that in many who have well-marked bone depression, epilepsy is never witnessed It is a well known clinical fact too, that moderate cerebral compression is entirely compatible with the healthy functions of the brain Extensive intracranial compression may produce pain, paralysis or coma, but that it in itself is ever a sole and direct cause of epilepsy is decidedly doubtful

In more than seven hundred fractured skulls, beside other serious traumatisms of the brain which have come directly under my care during the past fifteen years, I have found no direct evidences that a moderate indentification of its plates or intracranial pressure from effusion ever *per se* was the cause of epilepsy in any one who before the injury did not give a history of having had it at some earlier stage of life

With those who have an inherited or an acquired tendency to this disease, a cerebral injury undoubtedly often serves as a direct determining cause of its manifestations, and, with this class, we may, perhaps, expect the most satisfactory results from an operation on the brain when we have reasons to suspect pressure

On a comparatively superficial examination of the surgical literature of the past ten years, one is quite amazed at the vast number of cases of epilepsy that have been treated surgically during that period This is notably true of the Jacksonian and traumatic types Few surgeons could resist the seductive promises held out by modern investigators, with the apparent precision in cerebral localization and no serious peril to the patient Current medical publications, in both Europe and America, contain almost an infinite number of cases dealt with by radical measures yet, withal, it does not appear that any author has prepared a statistical table setting forth in detail the ultimate results It is obvious that such an undertaking, though highly valuable, would be quite impossible, for the reason that in a very considerable number the reports of several are so incomplete and indefinite as to be practically of no value Certain authors speak of "recoveries" after operations when it is not clear whether they refer to operative success or cure of the disease Very many are set down as 'recoveries" when the time that the patients were in hospitals was too brief, or they were too soon lost sight of

But very few have noted the influence of hereditary taint, sex, physiologic conditions, or antecedent history Enough, however, has been gathered to lead us to the conclusion 1, that trephining the skull is in itself, except in the hands of skillful surgeons, an operation which may endanger life, and 2, that, with only occasional exceptions, it makes no permanent impress on the course of the disease Gowers ("Diseases of the Nervous System," vol II, p 314) believed that "blows and falls on the head which cause symptoms of cerebral injury are sometimes followed by recurrent convulsions of an epileptoid character, leaving an impaired vitality of delicately constituted cells, the convulsions being local, owing to a local damage of the cerebral cortex" This view is difficult to harmonize with oft repeated clinical observations, and if rational does not explain how we may look for relief through tapping the skull

Gray says, that these cases of a peripheral origin usually improve under treatment, though a convulsive tendency clings to them ("Diseases of the Nervous System," p 375) This distinguished writer adds, that "trephining is a harmless procedure, under antiseptic precautions" The same writer tells us that some may enjoy an immunity from an attack from ten to fifteen years, and others a shorter time What we are desirous of correctly appreciating after a traumatism borne by the skull, and followed by epilepsy, is precisely the effect of this *alone* as an etiologic factor Before we can conclusively settle this important question, we must eliminate all extraneous influences, those already stated, beside the reflex neuroses, such as have been reported by various authors, a few of which may be enumerated St. Vilbis, in three severe cases of nasal catarrh, saw severe attacks of epilepsy which quickly ceased when this was relieved (*St Louis Medical Journal*, 1888, vol XVI, p 17) Robert saw a man have epileptic fits every time he had a severe attack of pleuritic pain. Another author cured his patient by removing an injured eye, while Bartholow saw cases which he believed were cured by the expulsion of orange seeds in the intestinal canal Le Grand Du Saulle (*Gaz Des Hopitaux*, 1885, LVIII, p 491) reported eight cases of epilepsy caused by viewing the dead body They were all females, from 12 to 28 years old, and in all there were histories of being the progeny of drunken or neurotic parents He accordingly observes that in all these cases there was enough to account for the onset of the malady, independent of fright or shock

In one of my own, the patient gave a history of having borne an injury to the skull in childhood With the aid of Dr M C O'Brian, the neurologist to the Harlem Dispensary service, I was enabled to localize the apparent intracranial mischief, and after removing a disk of bone, came down on a glioma as large as an egg, lying between the arachnoid and cortex, over the fissure of Rolando on the right side This was completely removed and our young man promptly recovered from the operation, but the truce was very brief, for in three months the convulsions returned with their old-time severity Echerexria throws some light probably on the cause of our failure, for he cites quite a similar case, ending mortally after operation, in which, on autopsy, several growths of a similar character were found scattered throughout the brain substance My patient gave a history of trauma in early life (*Arch de Med Gen*, t III, p 533)

From the accumulated testimony of a very large number of surgeons who are not disposed to "color" or report their cases in such ambiguous terms as to leave one in doubt of final results,we can only conclude that the number of cases of epilepsy capable of substantial relief or permanent cure through the resources of surgery is very small indeed We have no evidence that trephining makes any impression on the chronic type of a constitutional origin, those only dependent on local traumatism holding out any definite hope from cranial surgery

The afflicted are loath to admit that they inherit special diseases, and will resort to many subterfuges rather than acknowledge the truth This human frailty is peculiar to no particular class In many of these cases which come to us with scars on their scalps, no doubt, if we instituted a searching inquiry, we would find in some of them, at least, that they were produced by a fall in an epileptic seizure

In the general run of this class we will not find sufficient osseous compression to account for the epileptic seizures Some will say that there was a marked thickening of the plates of the skull where the trephine entered, but how can we determine this, except we are familiar with the relative thickness of the whole skull, which is quite impossible And so may there be patches of thickening of the dura mater or the meninges found, a similar condition often met with within the skulls of those who have died of maladies in no manner connected with the brain

It is certainly doubtful if moderate local depression of bone *per se* will cause epilepsy I have trephined and elevated depressed bone after cranial injuries more than one hundred times, either immediately after injury or within forty-eight hours, and in no single case have I ever seen epileptic convulsions follow, except when meningitis developed In one man an opening was made in the skull to drain a traumatic abscess which contained nearly six ounces of pus, but there were no fits, though we had reason to believe that the fluid compression had lasted more than a week In another man I removed, by *débridement*, several depressed fragments from his skull, which had been injured five years previously The fracture had produced an indentation that would admit the top of the finger and was located immediately over the torcular, which fact probably accounted for non-interference at the time of injury, through fear of hemorrhage He never had any convulsions and only came to us because there was a discharge from the necrosed fragments, which produced spells of irritation and pain in the scalp, which he wished relieved

We are not in a position yet to make any accurate estimate of the range of intracranial surgery in these cases of neoplastic growths, involving or within the cranium, which are presumed to provoke epileptic seizures If we are in possession of such definite data diagnosis as point with certainty to this malignant character, surgery is impotent to offer any relief, except by such perilous exploration as will place life in danger without any commensurate advantage Operative interference for the malignant class may be totally discarded

The myxomatous or gliomatous growths are those most frequently met with in the cortical or gray substance of the brain, and are the species of heterogeneous formations most often encountered in various forms of focal epilepsy They seem to bud from the stroma of the pia mater, usually are of small volume, have very thin walls and lie close to the under surface of the arachnoid Sometimes they are covered at varying depths from the surface by a layer of medullary substance In physical character they closely resemble the gummata of syphilis

Neurologists in many instances, are able to locate them with remarkable certainty, as I have seen demonstrated several times If the therapy of those cerebral affections accompanied with epileptic seizures was as definite as their diagnosis, the problem would be solved, for experience teaches us that, with few exceptions, after the evulsion or enucleation of these pulpy cysts, the tendency to many cerebral disturbances which they provoke continues The cerebral centers are then said to have acquired a habitual derangement, or have undergone such alteration in their elementary structures that operative measures in nearly all cases can only assure a temporary truce

The surgery of certain types of epilepsy to-day occupies a status not altogether unlike that of cancer, *i e*, in various clinical types it holds out no possible prospects of cure or even of relief

Like the dread scourge of epithelial proliferation, in rare isolated instances, after operation, epilepsy may not relapse Indeed, on the whole, it may be said that cancer is the more amenable to treatment, for the charlatan has always a large *clientèle* of those afflicted with this malady, though it is seldom that we see him advertise his "cures" of epilepsy

From the foregoing brief review of the surgery of epilepsy, the inference will probably be that, notwithstanding all that has been written of late years on the great advances of intracranial surgery, its application to those morbid conditions of the brain that gives rise to epilepsy in its various forms is so narrow and limited as to be practically of no avail

It has not been my intention to leave that impression, for it is my conviction that with the onward march of progress, in the near future a way will be opened through scientific reseach, experimentation and improvement in surgical technique, by which many of those afflicted with this disease will be greatly relieved, if not promptly cured Even now there can be no question but in a considerable number of the most aggravated type, though surgery can not promise a permanent arrest of the convulsive seizures, it may very greatly reduce their frequency, relieve the congested state of the vessels of the brain, diminish the dizziness and headache, displace despondency for buoyancy of spirits, and produce an entire psychic change for the better in the individual In the Jacksonian and traumatic types, though we may not be able to guarantee to our patients a definite cure, we may quite confidently assure him of a mitigation of his symptoms and a removal of the conditions which, if left undisturbed, in many are liable to lead to serious symptoms later in life Nevertheless, it has been my aim to warn against being too optimistic, or too sanguine in exacting from intracranial surgery, results which we well know at the present time we may not hope to realize in any but a small proportion of cases

115 West 49th Street

A MIXTURE FOR LOCAL ANESTHESIA —Le Gerant and E Pierre (*Le Moniteur Thérap*,, 1895, xxii, p 160) The following formula is given for local anesthesia, to be applied as a spray

Chloroform	10 parts
Ether	15 parts
Menthol	1 part

The anesthesia resulting from the application lasts about five minutes —*Am Med Surg Bull*, Dec 1

THE MORAL TREATMENT OF EPILEPSY

Read in the Section on Neurology and Medical Jurisprudence at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY H M BANNISTER, M D
FELLOW CHICAGO ACADEMY OF MEDICINE ETC
CHICAGO

In a discussion in the Chicago Academy of Medicine last October, I made some remarks on the *moral* treatment of epilepsy, the substance of which afterward appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and the *Medical Standard* The subject appears to me, however, extensive and important enough to justify me in again calling attention to it, and perhaps stating certain points more fully than was done on the occasion referred to

If there is any fact established in pathology, that epilepsy is a disorder of the cerebral cortex must be admitted as such While we may perhaps allow, with some of the Italian school, that in certain exceptional cases the basal ganglia may vicariate for the cortex in some of its functions, the general truth that convulsive manifestations, such as are characteristic of this disease and of cortical origin, may be considered as established It, therefore, is a disorder of the highest organ of the nervous system, one that is the organ of psychic functions, and its motor manifestations are most prominent on the very boundary line between psychic and non psychic affections

As might be expected, this being the case, we find that the disorder of which epilepsy is a symptom has close anatomic relations with mental disease which coincide with its clinical features It affects the highest controlling apparatus and the one also which reacts to every influence, moral and physical, that may affect the organism, and which in disease is the most liable to its disturbances in its functioning from all kind of external irritation In epilepsy, the condition of the brain is preeminently that of irritability, and the epileptic attacks of every type are only the extreme manifestations of this irritable condition In a very large proportion of cases in common life, this chronic irritability is hardly noticeable, and the attack has apparently little effect upon the mental functions or the character Yet, could we get all the facts in most of these cases it is highly probable, indeed, almost certain, that there would be found some exciting cause for the attack, and that often a psychic one, that was more or less avoidable At least this is true, I think, in the earlier stages, before the attack has become a sort of habit of the brain, periodically appearing without apparent cause

The treatment of the disease, therefore, would appear to include, not only the medicinal agents that can control this cerebral irritability, but also everything that may remove or favorably modify it, whether in the way of regimen, diversion, suggestion or physical control

The text-books, as a rule, say but little about anything but medical treatment by drugs and diet, etc The briefest mention is sometimes given to the general management and to moral treatment, and it might be inferred that this last is comparatively useless or unimportant To some extent this opinion exists and is due, I think in part, to the notion very generally taught, that all the inconvenient symptoms that accompany epilepsy, the attacks, minor and major, and the pre- and post-epileptic conditions are accompanied with unconsciousness, and that they are therefore not amenable to moral treatment The interparoxysmal irritable condition must, of course, be excepted, but this is generally spoken of as a profound alteration of character, due to irremediable organic lesions, and therefore itself irremediable These views I consider from my experience to be largely based on errors of observation The epileptic has frequently a consciousness of his surroundings, even in the pre- and post-paroxysmal condition, and when there is afterward complete amnesia, he is nevertheless more or less amenable to moral treatment during the continuance of these states I can give numerous facts supporting this view and shall include one or two later in this paper

Excluding all cases of epilepsy in which mental and moral changes are lacking, or, if existing, amount only to a gradually progressive dementia, we may divide the victims of this disorder as regards moral treatment into two great classes, those in whom the dangerous symptoms are transient and connected with the occurrence of the fits, and those whom the irritability and change of character render dangerous at all times In this first class we have patients who are comparatively rational for longer or shorter periods, in which they can appreciate their condition and provide for its emergencies During these periods they are as amenable to moral and prudential considerations as most people, they can realize the need of their restraint and will generally cooperate in any necessary measures if properly treated Sometimes they can exercise sufficient self control to decidedly modify pre epileptic conditions of irritability, as I have often observed

A patient of mine whose disturbed spells, though extremely violent, came on gradually, would confine himself to his room for days when he felt their premonitions, in order not to have them precipitated by any irritation or annoyance from other patients, and sometimes would escape the severer manifestations altogether He was often conscious of his condition, even in many of his worst attacks, but while normally a rather fearless man, when in the epileptic furor, which was to all appearance typical, he was never seen to attack any individual physically more powerful than himself The loss of the higher inhibitions seemed to make him cowardly while it made him violent, and this is a phenomenon I have more than once observed in furious epileptics who are supposed to have no more regard for prudential considerations than a mad dog

In one instance, an extremely violent post epileptic attack of maniacal excitement came to a sudden ending, due, I have reason to believe, to an encounter with an attendant whom we were obliged to discharge because of his treatment of patients That such measures are often employed against epileptic furor outside of asylums, I have the testimony of *intelligent* epileptics themselves, and one, at least, who had been used to a rough life, expressed his contempt of the hospital discipline that did not permit of such efficient treatment in his own case With perfectly humane and legitimate measures, however, it is possible by moral treatment to so modify the disturbed attacks of epileptics in a large proportion of cases, as to render them comparatively harmless Actual automatism, impervious to reasonable and tactful management is by no means so universal in these cases as the text-books would lead one to believe

It is advisable, in my opinion, to keep epileptics to themselves, away from other patients as far as possible, to obtain the best results from moral treatment. While irritable they are sympathetic and can appreciate each other's misfortunes, they are, I believe, less egotistic by far, as a rule, than the ordinary insane. There are, it is true, notable exceptions to this, and they have created the prevalent impression in regard to the whole, but what I say is true at least of the class now under consideration, which form a very large proportion of the epileptic cases in our asylums.

One important point in their management is to have strict but reasonable rules for their control. They are capable of appreciating the necessity of their sequestration, and can be reconciled to it if treated with kindness and consideration. Relaxation of rules can be granted as special favors or rewards, under careful medical oversight, with great advantage, but any indiscriminating laxity, or liberties granted as a right, will be apt to create trouble, as when they are necessarily taken away the patient is least fitted to appreciate his own condition and the need of the restriction. This, I take it, is one of the most important considerations in the management of this class of cases.

The second great class, those who from change of character or constant irritability are to be considered as always dangerous, are also generally more or less amenable to moral treatment. A few are morally insane, but even these have generally some utilitarian sense of what is to their advantage, and are therefore more or less amenable to legitimate asylum discipline. A very large proportion of the whole are reasonable, and will endeavor to cooperate with any judicious physician who gains their confidence, for their own good, and can be taught to exercise self-control to a greater or less extent. Together with the medical treatment to lessen their irritability, it is important to have these patients put under all possible favorable influences, and in some few extreme cases isolation from others to a larger extent is advisable. Some of the most irritable will voluntarily seek this, and if they can be kept sufficiently under observation it is perhaps the best course to favor them in this as much as possible. Moral influences are, however, not inapplicable in these cases, and occasionally the religious tendencies, so common in epileptics and which are, I think, undervalued generally in the treatment, can be utilized.

Many of these patients are not changed materially in their character, they are just what they would be without epilepsy, plus the irritability. Every exercise of self-control has a beneficial effect and religious motives, in which they are sincere, are often the strongest stimulus to this. In one of the most dangerous epileptics I have known, there occurred almost a complete change of character from this cause, while the irritability still existed it was constantly fought, and to a very large extent controlled by the patient's endeavors to live a consistent Christian life. It was a great trouble to him that he could not better succeed, but his dangerous tendencies were pretty effectually suppressed. A little encouragement and show of sympathy for the religious feelings of epileptics, allowing for their inconsistencies and failures as the results of their disease, will, I believe, often be a valuable aid to their management, at least in some well selected cases. In a large number it may do no good, but it is one of the facts that ought not to be slightingly considered in the moral treatment of epileptics. There is no greater moral and social force in the world than religion, and it is one for which epileptics afford a special field in a moral therapeutic point of view.

There are, of course, very great differences between epileptics, and individual treatment in the fullest sense of the word is required for every case. But it is true that, as a class, the epileptics are far more susceptible to what is known as moral treatment than seems to have been recognized by the majority of those who have written upon the therapeutics of their disease.

I have, in the foregoing, considered mainly the epileptics confined in our hospitals and asylums for the insane. Those who can be treated at home, from the only occasional epileptic to the mild epileptic dement, hardly call for moral treatment, though there is a degree of uncertainty as to the conduct and future of any one habitually subject to these attacks. Those, however, who fall within the two classes I have mentioned have their proper place in an asylum or special institution, and it is in such that what can be called moral treatment is applicable and useful. The separation from former influences, the subjection to necessary discipline, the regulated employment and diversions, are as essential and even more valuable remedial agents, than anything that can be prescribed in the way of drugs and diet. Patients who have been violent and troublesome, even to the extent of falling into the criminal class, under these new influences often become amiable, docile and industrious. I have one in mind who had been committed for violence and petty offenses some forty times, whose head was scarred all over with marks of clubbing and to whom fighting had come to be almost a second nature, who became in his way a model patient—cheerful, manageable and industrious, simply by being placed among considerate fellow-sufferers under a kind and tactful attendant. Undoubtedly there are many such who have been considered as dangerous, and really are under the condition of ordinary outside life, but who can be useful and happy inmates of a well-conducted epileptic colony, such as now are being proposed or started in various parts of the country. There will be a proportion who will require restraint, but the majority of these can be modified for the better, and life made happier and easier for them by judicious moral treatment. The incorrigibly bad, those who exemplify the epileptic character as it has been described, are but a small minority of the whole.

I have not directly mentioned, but have only indicated in the foregoing the hysterical element that exists in the case of most epileptics, and which, when we carefully study them, is often very clearly manifest. It plays a very important part in the character of many of these patients, but is often entirely overlooked in their treatment. We should, I believe, consider all pronounced epileptics as more or less hysterical, and adopt measures to meet this element in their case. Naturally, these will be largely in the nature of moral treatment.

While medical treatment is the mainstay in epilepsy of the milder types, that can be treated outside of institutions, it often is only secondary to the other measures mentioned, in the more advanced cases with dangerous tendencies and direct mental mpairment that compose the two great classes conidered in this communication

MY EXPERIENCE WITH SOLANUM CAROLINENSE IN THE TREATMENT OF EPILEPSY

Read in the Section on Neurology and Medical Jurisprudence at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md May 7-10 1895

BY C F BARBER, M D

BROOKLYN, N Y

In February 1893, my attention was called to the use of *solanum carolinense* in epilepsy, accordingly, I made an effort to learn something of its efficacy, also of its source before utilizing it in my practice

I found *solanum carolinense*, or, as it is more commonly called, horse nettle, bull nettle or sand brier, was not official It is not recognized by the U S Pharmacopœia, but a description short, it is true, is found in the Dispensatory of 1894 It is a native of Florida and Carolina but is found as far north as Connecticut, grows from one to two feet in height, branching, and is covered with shaggy hairs which are armed with stout, straight, yellowish prickles The leaves have the same armor for defense as do the stem and branches The berries which are the fruit of the shrub are utilized in preparing the preparations used in medicine, and when mature are of an orange yellow color The shrub prefers a sandy soil for its growth and is most tenacious of life when once established

Little has been written about the drug or its action, consequently there is little to review Krauss isolated wo active principles in 1894 solanin and solanidin Only two preparations have thus far been used, the fl ext and a 20 per cent tincture

The honor of placing this agent before the profession is due Dr J L Napier of Blenheim, S C In 1889 his paper was read before the South Carolina Medical Society and after explaining the results of his observations among the negroes who use the berries in whisky, making a tincture, he concisely depicted its results in his hands, which, I may add, were exceedingly encouraging Finding that the primary users of the berries were in the habit of administering them in cases of convulsions, the doctor ecured some of the preparation used by the negroes and administered it to a case of epilepsy which had baffled the energies of all the medical men in the vicinity and obtained surprising results One case after another, doing well under its employment, he gradually became a convert to it as a therapeutic emedy in epilepsy and allied disorders

Dr Geo F Foy, F R C S, in *Medical Press and Circular* (*Medical Age* 1890, p 18), refers to the reults of Dr Napier in a very complimentary manner and speaks as though he had much hopes from the drug

In March, 1893, I obtained from Dr A G Selman, of Indianapolis, a sample of the tincture My wards at the Kings County Hospital having many epileptics among their occupants, I at once placed several upon the use of the remedy At this time I subjected only those having the *grand mal* type of the disease to he use of the drug From one to six convulsive eizures is the record of these patients for twenty-our hours

As is the case in many instances where the drug is changed in the treatment of epilepsy, my immediate results were encouraging, for not a convulsion occurred for days For several weeks the improvement continued, some of the patients brightening mentally This latter condition may have been due simply to suspension of the bromid treatment In a few instances, slight drowsiness, and in one case vertigo was complained of These symptoms were quickly relieved by either lessening or suspending the quantity given

The individual histories of this series of cases, I regret to acknowledge, have been lost or mislaid I was not aware of this fact until after I had promised to prepare this paper at the solicitation of your worthy Secretary

In two cases, one of epileptic insanity the other having mild epileptic seizures, I had the pleasure of noting marked improvement in each instance The case of epileptic insanity had been under my caré at times for six or seven years with little or no improvement He had been subjected to all forms of treatment, but no favorable result, even for a short interval, was even noted until the drug in question was tried The attacks occurred in this boy both at night and during the day, the periods of insanity lasting from a few hours to several days While under the use of this drug, he brightened mentally and his convulsive seizures were reduced from three in twenty-four hours to two a week

In a little girl who had mild epileptic seizures, two or three occurring each week, I had the satisfaction of knowing that her condition was so much improved that her parents considered her cured I doubt this statement, but am willing to admit that the paroxysms were so mild in character that an untrained observer would consider them simply little nervous turns

In no case, thus far, have I seen the seizure cease entirely, as has been the experience with some of my predecessors in the use of solanum I have had no bad effects, save the slight dizziness spoken of and the drowsiness

I must ask the pardon of this Section for presenting this incomplete report, but as I can add some more positive data I shall hope to be excused for placing the foregoing before this distinguished body

My later investigations have been conducted with the fl ext of the drug obtained from Parke, Davis & Co The dose has ranged from half a drachm to half an ounce The ages of the patients from 8 to 50 years, and the cases have comprised those suffering from epilepsy with idiocy, epilepsy with insanity, epilepsy with *grand* and *petit mal* and epilepsy from traumatism The cases the results of trauma were of old standing and had been reported as cures, each having been operated upon They had however, from two convulsions in twenty-four hours to eight or ten in the same time

In observing my last experimental cases, I have been greatly aided by the watchful care of Dr F Welker, who has carefully tabulated the results from day to day Eight of the cases are attending the school for feeble minded children which is an outgrowth of the idiot ward

Of these, three are boys and five girls The girls, who are in the habit of having epileptic attacks each day, did well for a period of three weeks, not a convulsion occurring At the end of that time, however, I began to regret that I had ventured to test the usefulness of the drug, for at a most inopportune time they all had convulsions and from this relapsed into their former state, that is, the condition I found them in before beginning the use of solanum Although the dose was pushed, no improvement was noted and the treatment was abandoned

With the boys a different state of affairs prevailed They had an outbreak a few days following the girls but milder Another period of about a week's duration intervened, when they gradually relapsed into their epileptic state

Among the epileptics who were subject of *grand mal*, I had about the same results as I had experienced with the male epileptic idiots, save that the period of improvement continued longer and the relapse was more gradual Ten who were under the drug did not have a convulsion for twenty-nine days Then a case which was in the habit of having from three to six seizures per week had a mild attack, not being obliged to lie down This patient is mentally much brighter than he has been for some time and is now capable of doing light work about the ward, which is contrary to his condition in the past He now has his epileptic attacks, but they are milder in form than previously I will not take the time of this Section going into the histories of these cases, but briefly cite three or four cases as examples of my general results

Michael D , age 19 years, has been a subject of epilepsy for a number of years (exact period unable to ascertain, patient being an idiot) Patient had one seizure per week for a long period before taking *solanum carolinense* After placing the patient upon the use of the drug no improvement was noted

Mary H , age 23 years, has been a subject of epilepsy since her menstruation first appeared, is mentally bright save a period of slight stupor after a convulsion Before using the drug she averaged three convulsions per week Under the use of *solanum carolinense* she had an equal number and they were more severe in character

Henry K , age 35 years, has had epilepsy since 18 years of age Attacks followed the kick of a horse He will average one a day and very severe Patient is violent at times While under the use of the drug in question he had several a day and of great severity These are examples of many cases of which I have histories, but illustrate results obtained in my hands by the use of *solanum carolinense*

In the *Medical News* of recent date, Dr E D Boudurant, of the Alabama Insane Asylum, has placed his experience before the profession and his results are no more flattering than mine A few conclusions can be deduced from the work done with this drug

1 That *solanum carolinense* is not a substitute for the treatment now generally accepted for epilepsy

2 That it is a preferable substitute for the bromid treatment when compared with the biborate of soda

3 That it unquestionably has an influence over the disease, although mild It sufficiently controls the disease so as to warrant us in substituting it for a time to relieve our patients of the depression produced by the bromid treatment

4 Its toxic effects are nil

Dear Doctor —Please direct the attention of your friends to *our* JOURNAL. We will be pleased to send sample copies to any names you may suggest

THE SUPPLEMENTARY TREATMENT OF EPILEPSY

Read in the Section on Neurolology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10, 1895

BY A N WILLIAMSON, M D
NEW LONDON CONN

The brief paper to which I beg to call your attention for a few minutes is simply a plain commonsense talk on the treatment of epilepsy, my object being to point out how our ordinary methods of treatment may be supplemented and made more effective by closer attention to certain points too often considered of minor importance I do not know that any one is able to tell us very much that is new in regard to the etiology or pathology of this disease, but we may hope to make some advance in the matter of treatment I have lived with epileptics for the past fifteen years, have studied the disease in its various manifestations, and it is possible that what I have learned in regard to the minutiæ of treatment, the minor details which are beyond the reach of the general practitioner, may be of interest to you I shall not speak of epilepsy due to organic disease, where the convulsion is a symptom merely, but to *true* epilepsy, where, so far as we know, the convulsion *is* the disease

Now, we have the power through a certain remedy of controlling the manifestations of this disease to a certain extent, giving a patient certain relief for a month, three months, sometimes a year—when a relapse occurs If the convulsions can be successfully warded off for so long a time, and the patient kept in apparent perfect health, are we not justified in the inference that, by proper treatment and care, that period of immunity may be prolonged, perhaps indefinitely? What causes the recurrence of the attacks after a year's immunity? Is it, or is it not a preventable cause? If we are using the bromids is it because, after a time, they cease to influence the system as they did at first? We do not think so My experience leads me to the conclusion that the recurrence of the attack is due in most instances to *preventable* causes. There are three directions in which we can look for the causes of this recurrence

1 To the constitution of the patient and his capacity for tolerating the requisite doses necessary to control the spasm

2 To the condition of the digestive system

3 To the question of personal habits, exercise, occupation and personal discipline As to medication, the bromids are, from their positive value, in such general use that, in considering remedies, it is hardly necessary to refer to any other agent Yet, in spite of this absolute value and relative success, they are held in almost universal opprobrium by the laity everywhere

People who write to me for advice nearly always ask the question "Do you use the bromids?" to which an affirmative reply probably ends the correspondence Is this opprobrium deserved, or can we trace the fault to other sources? The bromids exert a powerful effect upon the system and the physician can not do justice to the patient or to himself unless he watches the effect carefully from day to day graduating the dose to suit the varying conditions of the case It is especially important in this disease and, in fact, in all diseases, to become early acquainted with the exact dose required in each individual case, in order to produce the effect sought. A dose which will profoundly affect one person, will be entirely inefficient in another. It is not uncommon to see epileptics, having a tendency to mania, driven into a positive outbreak by an overdose of the bromids. In such cases it can be used only with the greatest care and in small doses, even if at all. The patient must be kept under close observation and the remedy suspended at the first sign of mental trouble. In any case, the stage of full bromism should be avoided. If the bromids will not control the attacks until that stage is reached, we may be pretty confident the case is hopeless. It is my rule to push the dose to the point where the effect is only very slightly noticeable; mentally and physically the patient should be a little below the normal. To neglect, or inability of the physician to watch the matter carefully, we can easily trace one of the reasons why failure so often results from the use of the bromids. The immense amount of treatment done by quacks, through correspondence, has largely helped to bring the bromids into disrepute. There is no room to doubt, then, that a faulty administration of the remedy has much to do with bringing about a recurrence of the attacks.

Next to medication, and almost equally important, is the care of the digestive organs. To neglect of these organs we may undoubtedly trace a large proportion of our unsuccessful cases. General directions in this particular will not suffice. An epileptic is always balancing at the verge, ready to topple over into a convulsion at the slightest provocation; and if he has a weak stomach and poor digestion he stands little chance of obtaining permanent relief. And if we go back to the time of the first seizure, I am convinced that the one prominent factor, not only in exciting but perpetuating the attacks, is abuse of the digestive organs. Predisposing causes exist, either hereditary or peculiar to the individual case. I refer to determining causes. The books tell us that the convulsions of children are caused ordinarily by teething, worms, or fright, and in adults by self abuse, tobacco, or mental anxiety. Well, teething is a natural process, worms are seldom in evidence, and I have never yet seen a case in which the attack could be traced to fright or mental anxiety. But I have traced the cause, in many cases, to a stomach distended with indigestible food, or an intestine filled with impacted feces. In infancy, nature sometimes intervenes and relieves the over-full stomach by vomiting. But, too often, it is to a thoughtless mother or a careless nurse that we may attribute the first onset of this dreadful disease.

It is absolutely impossible to get satisfactory results from medical treatment if the stomach is given more to do than it can do with comparative ease. Whether the result is due to local irritation or to interference with the circulation, certainly undigested food is quite as probable a cause of convulsions as worms, and a cause much more frequently present. The habit of constipation is almost universal in this country, and often it is acquired in childhood. It must be overcome, one way or another, if any favorable results are to be obtained from treatment. An epileptic who is not habitually constipated is an exception. It is my rule to allow no patient to go over a day without a free movement. If necessary, an injection of tepid water is resorted to before retiring. In the matter of diet, constant watchfulness is necessary, both as to the quantity and quality of food taken. An ordinary plain diet, everything of the best, is safe in most cases, but the quantity must be rigidly restricted. Epileptics have often extremely voracious appetites which it is fatal to indulge. Relatives and friends can hardly be expected to possess the requisite judgment to act as a guide in such cases, and even with the best intentions their sympathies lead them to be over-indulgent. There must be no faltering in this matter. Food necessary for health and strength must be given, but none merely to gratify the appetite or fancy. We can not attribute the fault to the bromid if the patient is thrown into a convulsion by over-indulgence of the appetite.

In the matter of exercise, it is important that a physician's judgment should be always at command. Many persons entertain the belief that exercise, carried to the point of fatigue is injurious, and likely to provoke an attack. I have not found it so. On the contrary, exercise and plenty of it is a *sine qua non*. No patient with this disease thrives, if he is sluggish and inactive, with poor circulation and cold extremities. Those who are active, erect, quick in their movements, fond of outdoor exercise and work, are the ones who respond most readily to treatment, and are the least affected by the depressing influences of the medicine. A disposition to lie about, with round shoulders, shuffling gait, and pallid face, forebodes an unfavorable result. Where a patient's general health is good, he may work all day at manual labor, not only with safety but with positive advantage. In all my experience, and it is pretty large, I have never seen an attack brought on by fatigue. Constant exercise keeps the mind occupied, a very important point in this disease, stimulates the circulation, and gives a healthy tone to the whole system.

Another point looking in the direction of preventable causes of failure, is personal discipline. Epileptics are self-willed, obstinate as a rule, easily angered, and regardless of consequences; and especially need the controlling influence of a strong mind and a strong hand. Loomis says, in his "Practice," that mental impairment is not common in epilepsy. On the contrary, in my experience, it is the exception to find an epileptic whose memory, judgment and reasoning powers are not more or less weakened. Whether young or old, as a rule, they require a master; one to whom they will yield obedience without question, otherwise there is a constant struggle, which keeps both patient and guardian, whether physician or friend, in a constant turmoil. An epileptic child stands in far greater need of strict discipline than a healthy one, for his judgment being weakened, he yields more readily to the influence of passion or to temptation in any form, and has a lessened appreciation of his fault.

In the matter of treatment and its results, it is worthy of note that the milder manifestations of the disease, the *petit mal*, yield less readily to treatment than the severe convulsions. Where the two forms coexist, it is often possible to relieve the patient entirely of the severer seizures, while the slighter ones may persist indefinitely. I have found the bromid of ammonium, in the largest possible doses, to give more relief than any other preparation. In regard to the general use of the bromids, there are some authorities who advise pushing the remedy in full doses until bromism is reached, and then suspending its use until an attack occurs, repeat the same process

It is hardly necessary to say that this course results in final failure In the first place, as I said before, it is never necessary to push the remedy to the point of full bromism In the next place, our object is not to stave off the attacks for a time, and then suspending the remedy, wait and see if they recur, but, on the contrary, to keep the system under constant control, with the definite purpose of prolonging the period of immunity to the furtherest possible limit This is certainly the correct theory, if every added month gives the system additional power of resisting the onset

Since true epilepsy depends on such a condition of the nerve centers as can not be recognized by any means within our knowledge, we may fairly term it a habit, and, like other habits to which the system becomes habituated, the longer the period of abstention the less likelihood of a recurrence There is no permanence in the influence of the bromids, their influence is transient, and we can not continue the effect unless we continue the administration, for, ordinarily their controlling power is entirely gone in about thirty-six hours after their administration ceases

As regards the relative value of the different preparations, the bromid of potassium is without doubt, singly, the most efficacious, but I have found far preferable in a majority of cases, a combination of bromid of potassium six parts, sodium two parts, ammonium one part, given always before meals, and never more than twice a day, except in those cases requiring very heavy doses In cases requiring only from fifteen to twenty grains daily, I administer it in one dose In selecting the time for administration it is well not to forget the importance of interfering as little as possible with the digestive functions It requires a strong stomach to tolerate such a dose before breakfast, and, if given before retiring, a coated tongue and foul breath will commonly be in evidence in the morning

If we are seeking for preventable causes of a recurrence of the attacks in a case under treatment, none of these seemingly trifling points are of too slight consequence to deserve our serious attention It has been by this almost microscopic care of each individual case that I have been able to treat successfully, cases that had failed to obtain relief at the hands of men of far greater reputation and ability than I possess There is no question as to the permanent value of following out such an inflexible line of treatment as I have tried briefly to describe It is true that it is impossible to enforce such a rigid and systematic routine in general practice, but that does not affect the facts of the case To illustrate the results of the rigid surveillance I have described, permit me to refer to seven cases now under my treatment for periods varying from ten months to three years typical cases, presenting all the varied features appertaining to the true epileptic Ages, 10, 12, 15, 17, 20, 45 and 60 In five cases the disease began in infancy, in one, a robust man of 45, it had existed three years only, in another, a lady of 60 years of age, the attacks began thirty-five years previously In none of these cases, although they had all been under the bromid treatment, had there been less than two to six convulsions a week In one, a boy of 15, there was often as many as ten a day When they came under my care, I put them all on the bromid mixture to which I have referred I graduated the quantity of food with as much care and exactitude as I did the medicine I compelled a liberal amount of exercise in all weathers The result is worth noting The boy of 15, who had formerly from five to ten seizures daily, has not had a single attack since treatment began, twenty-three months ago, the boy of 10, under treatment for fifteen months, has had no attacks The boy of 17, whose case had been abandoned as hopeless, has now been free from attacks for five months The fourth case, a young lady of 20, has now been under treatment for three years with only one attack during the entire period, and that directly traceable to indigestion The lady of 60, who had weekly attacks for a period of thirty-five years, has had one seizure only in the past fifteen months, and that undoubtedly due to overeating The sixth case, a boy of 12, pronounced incurable by his physician, has been under treatment for eleven months, with one convulsion only, in which, by the way, he rolled from the top to the bottom of a long, steep flight of stairs without doing himself any injury The seventh case, a robust, strong healthy appearing man of 45, was entirely unable to make use of the bromid preparation in any dose, the effect being to induce a severe attack of mania Under the use of the oxide of zinc he has been kept free from attacks for upward of three months

It is evident that the favorable result in these cases has been due solely to the close personal supervision in all points to which they have been subjected I consider such a record exceptionally worthy of note, as showing the value of a closer attention to the minutiæ of treatment

---

PREVENTABLE DEAFNESS AND ITS INFLUENCE ON SUCCESS

Read in the Section on Laryngology and Otology at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md, May 7 10 1895

BY JAMES G H NICHOLS, M D
NEW YORK

The conception of government in its modern sense involves many ideas and tendencies formerly unthought of or unheeded, but which are beginning to be considered fundamental and necessary principles in their application to the present generation, and more especially to those following In our own department of thought and activity, preventive medicine has made great strides, and is now recognized as it should rightly be, as precedent and superior to curative medicine

The subject I wish to bring briefly to your attention is one which I believe to properly come within the scope of our discussion, and to justify such attention by its importance It is the occurrence of deafness in children, the causes of the same, and th question whether the State, through a properly qualified medical officer of the school board, should no insist on the early detection and remedying of this as well as other kinds of disease, as being an important factor in the after-success of the child and consequently in its effect on the general welfare of th community

Occurrence —First, as to the occurrence of deafnes in children, we find most commonly two varieties o ear disease, chronic suppurative otitis media an chronic catarrhal otitis media as the cause of deafness The former follows acute colds in the head the exanthemata or external causes, and become chronic from neglect, and a wide spread belief among the lower population that a running ear will stop spontaneously. To this most harmful notion is due the chronicity of the disease and the loss of hearing, for had the case been early attended the trouble could, in the great majority of instances, have been aborted without permanent injury to the middle ear structures. Over 40 per cent. of chronic suppurative cases give a history of beginning in childhood, but of having no treatment whatever until the impairment of hearing in adolescence became so great as to interfere with the occupation of the individual. It is certain that in most of these cases the disease could have been prevented entirely, or at least stopped in an early stage, had the parents been sufficiently intelligent to recognize the necessity for treatment, or, better yet, had the child on its first entrance into school life been subjected to a critical examination of its physical condition, as well as its mental acquirements. Recently two cases have come under my observation, both promising young men to whom entrance to West Point Military Academy was denied, solely from the existence of a chronic suppuration in one ear, not affecting the hearing in a marked degree, but still sufficient to debar them from a most useful and profitable life career. From the history of both these cases I am positive that had the attention of the patients been called to the disease by the school authorities on the boys' first entrance, this unfortunate ending could have been prevented.

Frequent colds in the head are a prolific source of acute ear disease, by simple extension through the tube. Here, again, is another preventable condition, due largely to improper hygiene, both at home and at school. The Americans are not a bathing people, and I have observed that children when they reach the age of 4 or 5 years cease to receive their daily bath, and it becomes a weekly or bi-weekly function and then a warm one instead of a cold one. It is not necessary here to more than refer to the immense prophylactic influence of daily cold tubbing in catarrhal diseases, and I fail to see why this habit of cleanliness and health should not be inculcated in the child and included early in its instruction, as well as instruction as to the effect of alcohol on the system, or the science of government.

The second class of cases consists of the chronic catarrhal ones, even more important, because so insidious is their onset and so slow their progress. They are the sequels in some instances of the chronic suppurations, but much more largely due to obstructive condition of the upper air passages, such as adenoids, hypertrophied tonsils, deviation of the septum, chronic hypertrophic rhinitis and pharyngitis, the percentage is about 65 per cent. in which these conditions are found, and they are all remediable and are demonstrated facts. Why wait until a chronic catarrhal condition has become established, why not detect it early when there is every hope of success in curing it? I need not enlarge on the presence of cases like this. The observations of Chaphill and others prove them. Admitting that deafness in children is in most cases due to preventable causes, we are led to ask what are the respective responsibilities of the State and the parent in this matter? Abstractly regarded as a matter of self preservation and progression to higher civilization, the State has the right and the duty to supervise the health of its citizens. This is conceded by the establishment of boards of health to enforce sanitary laws of general application in the drainage of communities, their water supply, the construction of houses and the control of epidemics and contagious diseases. More recently local legislation compels vaccination among all school children at stated intervals, inspection during certain seasons of tenement houses and institutions, isolation of suspected cases, reports of diphtheria, with disinfection of premises, etc. Some States go a step further. New York, for instance, requires midwives to report *instantly to a qualified practitioner* any case of ophthalmia neonatorum arising in their practice. Legislation is even being agitated looking to the compulsory examination of the eyes of school children with a view to the discovery of latent astigmatism, myopia, etc., and advanced ophthalmologists have taken great pains to investigate the proper lighting of school rooms, the position of pupils in regard to the light, and in regard to their work, the ventilation of the room, and they have found, as in Snell's most recent report in the *Medical Annual*, overwhelming evidence of the importance of early attention to small things.

The ear, the nose and the throat are at least as necessary to perfect health and comfort as the eye, and, commercially, as valuable to the possessor. Why should not the community, therefore, in its general oversight of the health of its constituent individuals take upon itself also the detection of diseases of the eye, ear, nose and throat as a matter of routine in its educational scheme? In other words, the physical condition of the child should be inquired into, as well as his intellectual condition *at the start*, and thereafter at regular intervals *pari passu*, by a regularly constituted examiner attached to the school board. Owing to the advanced state of post-graduate instruction, there are numbers of qualified men available for such positions, but any practitioner competent to fill the post of health officer to a community, would also be competent to apply such tests as would serve to detect the existence of disease, and if not to treat them, to refer the parents to the proper place for treatment, indeed, it is not a part of the duty of such an officer to undertake the treatment of such cases unless in case of poverty, but simply to discover them, make them a matter of record and properly notify the parents or guardian of the necessity for treatment. Such a scheme consists of the following essential points.

1. The appointment in every school district, by the school board, of a properly qualified medical man, whose duty it should be to attend on the registration days at school and examine all the children presenting themselves for the first time, as to their vision, hearing, condition of nose and throat, freedom from contagious disease and habits of cleanliness. He should make a record of the same in the school register and, should any disease be found, should notify the parents, on a proper blank, of its existence and the need of treatment.

2. During each school year he should examine every child in his district in the same manner and should keep a record of the same, and note if his recommendations have been complied with.

3. The medical examiner should supervise the heating, lighting and ventilation of the school rooms and should have power to enforce his recommendations. He should, at stated intervals during the year, give instructions to the pupils, and by circular letter

to the parents, in regard to the care of the eye, ear, nose and throat, and general hygiene

Legislation to this effect will be sought in New York during the next session of the Legislature, and while it is not thought that the time is ripe for such an advanced law, yet the value of constant agitation is very great, and it is hoped that this body will voice its approval of the principle involved, and that its members will aid in every way possible to bring the matter before the public

DISCUSSION

DR LEWIS H TAYLOR—While the paper just read, Mr Chairman, does not present anything especially startling, I, nevertheless, think it one of the most important papers read before this or any other Section A few years ago I heard a gentleman, in discussing diseases of nose and throat, say that every one should use an atomizer with proper solution to cleanse his nose and throat with the same regularity as he would brush his teeth, and as part of daily toilet I thought this an exaggeration, but the more I investigate the subject of deafness the more I am inclined to think he was right, for it is mainly by correcting the catarrhal trouble that we may prevent chronic deafness There is presented this afternoon in the Section on Ophthalmology, an elaborate report on the investigation of the eyes of school children, and this will be followed, no doubt, by action of the Section, looking toward securing legislation on this important question, the preliminary steps having been taken at the San Francisco meeting The examination of the hearing of school children is no less important, and I hope this Section will express its approval of the suggestions made to this end by Dr Nichols

---

REPORT OF THE COMMITTEE ON THE DISPOSAL OF THE DEAD

Read before the American Public Health Association, held at Denver, Colo , October 1-4, 1895

BY C O PROBST, M D , CHAIRMAN

COLUMBUS, OHIO

The proper disposal of the dead is a matter which greatly concerns the living The dead have been disposed of in various ways in different times and places, no useful purpose will be served by going into the history of the subject, and this report will be confined to the consideration of cremation and earth burial The history and progress of cremation in the United States (there are no crematories in Canada) will be reported upon briefly, and an attempt has been made to summarize the laws of the various States and provinces, with respect to disposal of the dead, more especially as to sanitary considerations taken note of in such laws Rules and regulations of State and provincial boards of health, as affecting this question, have also been given as far as possible

The first crematory in the United States was established at Washington, Pennsylvania, in 1876, by Dr F J Le Moyne It was used for the first time on December 6 of that year, when the body of Baron de Palm was cremated Dr Le Moyne's crematory excited great local opposition, and this local feeling, apparently, was never overcome, for the only resident of Washington to be cremated in this furnace was Dr Le Moyne himself In 1884 this crematory was practically closed by the decision of the trustees to limit its use to those living in Washington County, and there have been no applications and no cremations there since Thirty-eight bodies were cremated, twenty-nine males and nine females

The second crematory was also in Pennsylvania, at Lancaster, and was opened Nov 25, 1884 Three bodies were cremated in that year, thirty-six the following year, but not more than fourteen in any year thereafter The secretary of the company, Mr J D Pyatt, writes "We do little work here now, we got in our work as pioneers, and have spent six or seven thousand dollars doing it, with no dividends " Eighty-nine bodies have been cremated, only nine being bodies of residents Sixty seven were males and twenty-two females Death was due to contagious disease in thirteen cases

The following year, 1885, the most successful of all the crematories in the United States was opened at Fresh Pond, Long Island, N Y Five bodies were cremated in that year, 82 the next, and in 1894 there were 254 To August 28 of this year there were 208 cremations, making a total of 1,554 Of these 1,084 were males and 470 females Including phthisis pulmonalis, 290 died of contagious disease It is interesting to note that 806 of those whose bodies were incinerated were born in Germany, 513 in the United States and the rest in the various countries of the world

In 1886 Pennsylvania established her third crematory, and New York her second The one in Pennsylvania was constructed at Pittsburg by Mr Sampson, an undertaker The number cremated to the end of 1894—the latest date available—was 100, 63 males and 37 females

The second New York crematory is at Buffalo, and was opened with a test incineration Dec 27, 1885 Eight were cremated in 1886, 37 in 1891, the greatest number in any year since, and 29 to September 5 of the present year The total number is 250, 166 males and 84 females One hundred and forty eight were residents and 102 non-residents

In 1887 three crematories were added to the list, one at Cincinnati, one at Los Angeles and one at Detroit The Cincinnati crematory was opened June 22, 1887, and 11 were cremated that year The number increased to 46 in 1894, and for 1895, to August 16, there were 44, making in all 314 Two hundred and fourteen of these were males, 100 females, and 38 were children under 15 years of age Two hundred and forty were residents, 74 non residents, and 62 died of some contagious disease The Detroit crematory was opened Dec 10, 1887 The greatest number cremated in any one year since, was 45 in 1893, the total number to April 20, 1895, was 183 Of these 125 were residents and 58 non-residents One hundred and eleven were males and 72 females, 24, counting phthisis pulmonalis, died of some contagious disease Only partial statistics were obtained from Los Angeles The crematory was opened June 6, 1887 Seven bodies were cremated that year The greatest number in any one year since was 41 in 1892 The total number to the end of 1894 was 182, 119 males and 65 females

It is an interesting fact that the name of the President of the Cremation Society of Southern California, having its crematory at Los Angeles, is Dr Wm *Le Moyne* Willis

St Louis and Philadelphia established crematories in 1888 According to the report of the Bostonian, it is peculiarly fitting that Philadelphia should be well provided for the disposal of the dead The Bostonian was showing a Philadelphia friend over Boston The Philadelphian remarked "You have a great city here, but you are not nearly so well laid out as Philadelphia " "True," retorted the Bostonian, "but we doubtless will be when we are as dead as Philadelphia "

The Philadelphia crematory was opened in May, 1888 There has been a gradual increase in cremations, with 70 in 1894, and 75 for 1895 to August 11, the total number is 399, of which 264 were males and 135 females Three hundred were residents and 99 non-residents Twenty six of those cremated died of a contagious disease

The St Louis crematory was opened in 1888, since which time to Sept 18, 1895, 137 bodies have been cremated The number has gradually increased from year to year, with 70 for 1894 Three hundred and forty of those cremated were residents, 97 non-residents Three hundred were males and 137 females None died of a contagious disease

Baltimore established a crematory in October of 1889 Up to May 14 of this year only 84 bodies had been cremated, 57 males and 27 females None died of a contagious disease

In the same year a crematory was constructed on Swinburn Island for the destruction of the bodies of those dying of a contagious disease in quarantine or on vessels at New York To the end of 1894, the latest information at hand, 109 bodies had been incinerated

In 1890 a crematory was built at Troy, N Y, by Mr and Mrs Earl for their only son, Gardner To the end of 1894, 56 bodies had been cremated, 37 males and 19 females

The following year, in March, Davenport, Iowa, erected a crematory Thirty six cremations have occurred there to April 20, 1895 Of these 27 were of males, 9 of females

The same year, 1891, Mr Wm Osborn of Waterville, N Y, erected and donated a crematorium to the Waterville Cemetery Association Only 5 bodies have been cremated there to August 16, 1895, 4 males and 1 female, one being the body of a resident

The year 1893 witnessed the building of crematories in three important cities Chicago, San Francisco and Boston

The Chicago crematorium was opened in December, since which time to August 27, 1895, 87 bodies have been incinerated Of these, 54 were males, 33 females, 60 were residents and 27 non-residents One person died of a contagious disease

The San Francisco crematory was opened Nov 12, 1893 On May 1, 1895, 200 bodies had been incinerated, 112 males and 88 females One hundred and thirty of these were American born Three died of a contagious disease

Boston inaugurated cremation next to the closing day of 1893, the person cremated being a resident of Massachusetts In 1894, 97 persons were cremated, 78 of them being residents of the State In 1895 to April 22, there were 30, with 22 of them residents In all there have been 118, a very good beginning Here, as was to have been expected, women have had equal rights, (not rites) and 59 males and 59 females embraced the new faith of cremation Four of the subjects died of diphtheria, 3 of influenza and 1 of typhoid fever

The latest crematory to be constructed was the Odd Fellows Crematory at San Francisco The first incineration took place June 25, 1895 Up to August 22, 28 bodies had been cremated, 18 males and 10 females None died of a contagious disease

The total number of persons cremated in the United States at the close of this inquiry was 4,261 Omitting Swinburn Island, from which information as to sex was not obtained, there were 2,783 males and 1,369 females

The main reason for the great preponderance of males doubtless is the number of cremation societies that have been established, composed largely of males, whose members make provision for the cremation of their bodies at death

Omitting Pittsburg and Buffalo, from which information could not be obtained, 526 of those who were cremated died of some contagious disease, about 13 per cent

Nearly all of these crematories are managed and operated by joint stock companies The usual price for cremation is $25 The highest charge is at San Francisco, which is $60

Massachusetts, Michigan, Pennsylvania, California and Ohio are the only States, so far as found, whose laws recognize cremation in any way, and Massachusetts seems to be the only one in which cremation is fully regulated and controlled

The only objection urged against cremation, aside from sentimental reasons, is that cremation destroys evidence of crime Cremationists claim that the extra precautions taken to verify the cause of death give, in reality, greater security against this than does earth burial, as ordinarily practiced The usual precaution in this country is to require the affidavit of a physician, not necessarily in all cases the attending physician, "that to the best of his knowledge and belief there exists no reason why the deceased person should not be cremated " This is sworn to before a notary, or justice of the peace, who certifies that the affiant is by him known to be a physician of good standing Several crematories accept bodies for cremation when accompanied only by the ordinary board of health permit, this permit being issued, however, only on presentation of a certificate from the attending physician as to the cause of death It will readily be seen by those familiar with the usual methods of issuing certificates, that the opportunity this offers for concealment of crime is very great Even an affidavit by the attending physician, with certificate of the notary as to his standing, when the body is brought from abroad, affords no adequate barrier against this danger

In Massachusetts the location and construction of crematories must first be approved by the State Board of Health The Board also establishes the regulations which shall govern their use, and the body of a deceased person may not be cremated until forty-eight hours after death, unless due to a contagious disease In addition to the customary burial permit, which is issued only on certificate of the attending physician as to cause of death, there must be a certificate from the medical examiner of the district within which the death occurs This applies to the States of Massachusetts, Connecticut and Rhode Island Dead bodies from other States must be accompanied by the sworn statement of two physicians, each of whom must be a graduate of some "legally organized medical college," and one of whom shall have been the attending physician Even this would not give very great protection in the case of dead bodies sent from Ohio, and some other States, where "legally organized medical colleges" are graduating some very disreputable persons

Table showing Location, Date of Opening, etc, of Crematories in United States

Location	Date	Number Cremated	Residents	Non residents	Male	Female	Number died Contagious Disease	Charges Dollars
Washington, Pa	1876	58	1	37	29	9	none

San Francisco, Cal	1895	28			18	10	none	

We may now turn our attention to earth burial, with special reference to the laws and regulations governing it in the United States and Canada

The opinion is quite generally held by all classes of people, that crematories and earth burial, unless properly controlled, may become a menace to public health, and one is surprised to find that so little consideration has been given to the subject by legislative bodies In more than half of the States, beyond making provisions for establishing and maintaining cemeteries, no attention whatever has been paid to the disposal of the dead In but one or two States has the possibility of contamination of water supplies by drainage from burial grounds been considered, and few have by legislative control guarded the dangers attending the disposal of the body of a person dead of a contagious disease A permit for burial, issued only after receipt of a proper certificate as to the cause of death, is absolutely essential to prevent dangers from contagion and to avoid concealment of crime, but the great majority of our States have made no provision for this It is true that, as a rule, this measure is enforced by the local authorities in the large cities In but few States have the health authorities been given any powers to regulate the location or use of cemeteries Laws for the prevention of intramural burial have been enacted in several States, but they often fail in their purpose, the growth of cities gradually approaching and finally including the burial grounds

A few States have provided against the dangers arising from the disinterment of bodies of persons who have died of a contagious disease Three or four have regulated the depth of burial Burial within churches is still permitted in the Province of Quebec The laws of this province, however provide against a danger which has not been recognized, so far as can be learned, in any other province or State That is, permitting a body dead of a contagious disease, to be taken into a public receiving vault

The laws of Massachusetts and New Jersey with reference to disposal of the dead seem to be superior, in most respects, to those of other States A summary of these may be read, omitting, to save time, those of other States and provinces, which are included in the report

Massachusetts Boards of health may make all regulations which they judge necessary concerning burial grounds and interments within their respective limits, may close any cemetery or burial ground within the city or town they may deem necessary to protect the public health, may prohibit any person unless appointed an undertaker or otherwise authorized by the Board of Health from burying or moving a deceased person

No deceased person can be buried without a permit issued by the Board of Health on receipt of a certificate of death by attending physician or coroner. (Laws of 1885–87)

New Jersey Location of new cemeteries and extension of old ones must be approved by the municipal authorities and the local board of health, subject to revision by the State Board of Health Descriptive map must be filed with the State Board of Health. Top of outside coffin, for adults, must be buried four feet beneath the surface, for children three and one-half feet This does not apply to properly constructed private vaults Municipal authorities and boards of health are authorized to inspect cemeteries Disinterment of dead bodies is forbidden between May 1 and November 1, except for purposes of criminal investigation Forbidden at all times when death was caused by a contagious disease unless body is in a metallic hermetically sealed case, and then only by order and under supervision of local boards of health.

Cemeteries may be closed by Court of Chancery on application of municipal authorities, local or State Board of Health (Laws of 1885)

A certificate as to cause of death must be given by attending physician or coroner in all cases In cities or other local municipal government a permit to bury must be obtained in exchange for the death certificate

Local boards of health may prohibit public funerals where death resulted from a contagious disease. (Laws of 1888)

Many of the State and local boards of health have supplemented or strengthened the laws of their respective States with reference to disposal of the dead, more especially with respect to the care of the bodies of those who have died of a contagious disease

It will appear from the foregoing that our dead have been disposed of with but little control by any constituted authority, and without much attention to sanitary regulations, and yet the harm, apparently, has not been great, and perhaps none at all, except where burial was in the crowded parts of cities

There is a growing feeling that the dangers apprehended from cemeteries have been considerably overestimated Before much was known about bacterial agencies of disease, many evils which could only be conjectured were charged to cemeteries As the science of bacteriology was gradually unfolded, an explanation of how cemeteries may produce disease was afforded by supposing that the germs of infectious diseases, buried with their victims, infected the air and water in their vicinity Outbreaks of contagious disease near burial grounds were often attributed to this cause without seeking for positive proof

More recently many investigations have been made to determine the viability of pathogenic organisms in the soil, and the possibility of their infecting surrounding water and air in earth burial of the dead Koch, Kitasato, Heser, Esmarch and Petrie agree in discrediting the claims of Pasteur that the earthworm may bring the spores of anthrax, buried with cattle, to the surface and renew the disease in cattle feeding in such burial grounds Dr Petrie's experiments showed that the bacilli of cholera, and typhoid fever, when injected into animals which were killed and buried, lived but a short time Reimer's investigations in cemeteries at Jena did not show any increase of bacterial life along side or beneath dead bodies as compared with control ditches dug in similar adjoining soil Proskauer, in Berlin, met with the same results

The bacteriologic examination of wells in cemeteries has failed to demonstrate contamination A series of monthly chemic analyses of the water from the wells in cemeteries of the city of New Haven, Connecticut, were made by Dr Herbert E Smith, in 1889-90 Summing up the results he said "It would seem to justify the inference that a cemetery with a deep sandy subsoil would be very unlikely to contaminate the ground water at any considerable distance from the cemetery" This agrees with the conclusions of Professor Fleck, who examined the water from cemetery wells at Dresden

In 1875 Dr Adams, of Massachusetts, made an *exhaustive report on disposal of the dead*, which is published in the report of the Massachusetts State Board of Health for that year He said "In summing up this investigation, we can not avoid the conclusion that, so far as it goes, it shows that any injurious influence exerted upon the public health by burial grounds, as at present managed in this State, as well as throughout the United States, is almost unknown"

In spite of the lack of evidence to convict burial grounds of being a cause of disease we are far from urging that they are, under all circumstances, free from such danger We have conditions very similar to earth burial in the deposit of fecal matter in holes in the ground Bacteriologists tell us that the bacilli of cholera and typhoid fever are soon destroyed in such places, but we have many instances which seem to conclusively prove that a well near such a vault may be infected

On the other hand, one of us has knowledge of two cities built on deep beds of sand and gravel where it has been the common practice for years to construct open cesspools equal in depth to the wells Typhoid fever has not prevailed to any great extent in either of these places, and those still using well-water have not suffered more than those using the public supply, taken from another source Doubtless the character and condition of the soil largely determine the danger in such cases, and such is probably true, to a greater or less extent, in earth burial

From present knowledge we would summarize our conclusions follows

1 Cremation is to be favored as a safe and cleanly method of disposing of the dead

2 Cremation in the United States, at least for many places, needs further safeguarding to prevent concealment of crime

3 Earth burial, under proper conditions, is also a safe and satisfactory method for disposal of the dead

4 The location, preparation and use of burial grounds should be controlled by statutes, under the direction of boards of health

5 Intra-mural burial should be prohibited, and a considerable space in which there should be no burials should be provided around the outer areas of cemeteries to prevent the encroachment of dwellings

6 Cemeteries should have a loose porous soil, underdrained, and precautions be taken to protect sources of water or ice supplies from such drainage

7 Closed vaults, and indestructible receptacles or coffins for the dead, *should not be used, the* body being permitted to return to dust as rapidly as possible

8 Separate graves, with sufficient space between them, should be required

9 No one should be permitted to dispose of a corpse without a permit from a proper authority, to be issued only after satisfactory evidence of the cause of death

10 Only licensed undertakers should be permitted to dispose of the dead, and under such restrictions as may be imposed by health authorities

11 The body of a person who has died of a contagious disease should not be permitted in a public receiving vault, and public funerals in such cases should be prohibited, special precautions being taken to guard against the conveyance of contagion by those who have been associated with the deceased

PUBLIC STATUTES, AND REGULATIONS OF STATE AND PROVINCIAL BOARDS OF HEALTH IN RE-LOCATION AND REGULATION OF BURIAL GROUNDS AND DISPOSAL OF THE DEAD

United States

Alabama Physicians required to give certificates of death to the county health officers "No law requiring burial permit Most cities and towns have ordinances requiring such permits" (Dr Cochran, State Health Officer)

California The bodies of those 10 years of age and upward must be buried in graves six feet deep, of those under 10, five feet Disinterment permitted only on order of board of health, health officer, coroner or mayor, issued on certificate from coroner or attending physician, giving cause of death, etc Body must be inclosed in a sealed metallic case or coffin (1878) In incorporated cities or counties, burial permits must be obtained from the health officer or board of health issued on death certificate of attending physician or coroner (Laws of 1889)

Colorado Cemeteries located in cities, towns and villages may be vacated by order of a county court on petition of the local board of *health* (*Act* of 1893)

Disinterment of dead bodies is forbidden except by permission of the State or local board of health (Rules of State Board of Health)

In the city of Denver, death certificate is required of physician or coroner, and burial permit must be obtained from the board of health (Laws of 1895)

Connecticut Cemeteries not hereafter to be located within 600 feet of any ice pond, nor any ice pond to be located within 600 feet of any cemetery unless the ice pond is on higher ground (Laws of 1889)

No cemetery hereafter to be located within one-half mile of any reservoir furnishing a public water supply, and no such reservoir to be located within one-half mile of any cemetery Subject to revision by county superior court (Laws of 1884)

Town registrar issues burial permit on receipt of death certificate given by attending physician or medical examiner

In contagious diseases the undertaker must, in addition, give the registrar a sworn statement that the body has been prepared according to the rules of the State Board of Health (Laws of 1893)

Delaware "The bill passed by our Legislature regulating the disinterment, burial and removal of dead bodies in this State is lost, and therefore we have no law upon the subject except in the city of Wilmington" (Dr Frazer, Secretary State Board of Health)

Florida "No laws on burial, or regulating location or management of cemeteries In large towns regulated by ordinance" (Dr Porter, Secretary State Board of Health)

Rules of State Board of Health provide that dead bodies shall not be disinterred between April 15 and December 1 When dead from contagious disease not until two years after death, and then placed in a "practically air-tight case"

Illinois Trustees may decide and direct the depth that graves shall be dug (Laws of 1887)

Rules of State Board of Health prohibit public funeral when death is due to a dangerous contagious disease

Indiana "No State laws regarding disposal of the dead Burial permits only required in large cities" (Dr Metcalf, Secretary of the State Board of Health)

Rules of State Board of Health prohibit cemeteries within less than one mile of corporation limits of any town or city Require private burial (coffin to be unopened) as soon after death as possible, when death is due to a contagious disease

Iowa Municipal corporations have power to regulate the disposal of the dead Rules of the State Board of Health recommended for adoption of cities, towns and local boards of health, provide for a burial permit issued by clerk of the board of health on receipt of certificate of death by attending physician or coroner

Rules provide that disinterment shall only be permitted by authority of State Board of Health No disinterment permitted when death is due to Asiatic cholera, smallpox, scarlet fever, leprosy, typhoid (?) fever or yellow fever

Kansas Rules of State Board of Health require that in death from contagious disease the body shall be wrapped in a disinfected cerecloth, inclosed in an air-tight coffin and allowed to remain in the sick room until removed for burial Public funerals in such cases not allowed

Disinterment only on permission and under direction of local board of health

Maine Cemeteries shall not extend nearer than twenty-five rods to any dwelling house against written protest of the owner" (Dr Young, Secretary of Board of Health)

Death certificate obtained by undertaker, who presents it to the city or town clerk, who issues burial permit

Certificate is not required where it is impracticable to obtain it within reasonable time after death (Laws of 1895)

Massachusetts Boards of health may make all regulations which they judge necessary, concerning burial grounds and interments within their respective limits, may close any cemetery or burial ground within the city or town that they may deem necessary to protect the public health, may prohibit any person unless appointed an undertaker, or otherwise authorized by the board of health, from burying or moving a deceased person

No deceased person can be buried without a permit issued by a board of health on receipt of a certificate of death by the attending physician or coroner (Laws of 1885-87)

Michigan The trustees of any incorporated village, or council of any city, may cause any cemetery to be vacated when it endangers the health of the people living in its vicinity, but not during the months of June, July, August or September (Sec 4790 of the R S)

No person dead of any dangerous communicable disease may be brought into any township, city or village, without a special permit from the board of health or health officer, and under the health officer's supervision (Laws of 1895)

Minnesota Physicians are required to report to local boards of health the death of any of their patients who shall have died of a contagious disease within twenty-four hours thereafter

Corpse shall not remain unburied longer than four days, or if death is caused by contagious disease not longer than twenty-four hours after death, without permit from local board of health If death is due to a contagious disease the said board may cause the body to be disinfected, and tightly sealed in a coffin, which shall not be opened Funeral in such cases must be private (Laws of 1883)

Nevada It is unlawful for an undertaker or other person to bury any deceased person who has died in any incorporated town or city in the State without having first obtained a certificate from the attending physician or coroner This permit, before burial, to be returned to the coroner of the county where the deceased died

County commissioners may authorize disinterment of dead bodies when, in their judgment, it will not endanger the public health, provided the person to be disinterred did not die of a contagious or loathsome disease (Laws of 1865)

New Hampshire No cemetery shall be laid out within twenty rods of any dwelling house, store or other place of business without owner's consent (Chapter 51, Sec 2, R S)

Cause of death must be certified to by attending physician "No dead body may be buried without a permit In cities no permit issued till application has been passed upon by the board of health" (Dr Watson, Secretary of State Board of Health)

New Jersey Location of new cemeteries and extension of old ones must be approved by the municipal authorities and the local board of health, subject to revision by the State Board of Health Descriptive map must be filed with the State Board of Health

Top of outside coffin, for adults, must be buried four feet beneath the surface, for children, three and one-half feet This does not apply to properly constructed private vaults

Municipal authorities and boards of health are authorized to inspect cemeteries

Disinterment of dead bodies forbidden between May 1 and November 1, except for purposes of criminal investigation Forbidden at all times when death was caused by a contagious disease unless the body is in a metallic hermetically sealed case, and then only by order and under supervision of local board of health

Cemeteries may be closed by Court of Chancery on application of municipal authorities, local or State Board of Health (Laws of 1885)

A certificate as to cause of death must be given by attending physician or coroner in all cases In cities or other local municipal government a permit to bury must be obtained in exchange for the death certificate

Local boards of health may prohibit public funerals where death resulted from a contagious disease (Laws of 1888)

New Mexico Municipal corporations may establish and regulate cemeteries within or without corporation, may cause cemetery to be removed and prohibit them within one mile of corporation (Laws of 1884) Burial prohibited within 250 yards from either side of a river or stream (Laws of 1889)

An act of 1889, appointing boards of health, forbids carrying a contagious corpse through streets or roads, or into any church with coffin open and body exposed "This was a common practice with the Mexicans, even in smallpox " (Dr Atkins, Secretary of Territorial Board of Health)

New York Local boards of health are required to "prescribe sanitary regulations for the burial and removal of corpses "

The undertaker is required to secure a certificate of death from attending physician or coroner, and must present this to the local board of health to obtain a permit for burial or removal (Laws of 1893)

The Board of Supervisors of any county may make such regulations in regard to burials as the public health may require

No cemetery shall be located within less than 100 rods from any dwelling, without the owner's consent (Laws of 1854)

North Dakota "No law regulating location or use of cemeteries except that bodies must be buried with four feet of earth on top of the coffin " (Dr Montgomery, State Superintendent of Health)

Corpses must be buried within four days after death, and where death was due to a contagious disease, within twenty-four hours after death, except by permission of the local board of health In contagious diseases the funeral shall be strictly private, and only such hearses or other vehicles shall be employed in the removal of the body as may be authorized by the board of health

Undertakers are required to have death certificate from attending physician or undertaker, which he files with the board of health after burial of the body (Laws of 1893)

Ohio Cemeteries not permitted to be established within 200 yards of any dwelling house, unless owner consents In enlarging a cemetery it shall not be nearer than 100 yards to any dwelling house erected subsequent to the location of the cemetery (Laws of 1891)

Disinterment of dead bodies prohibited from April to October, and at all times when death was due to a contagious or infectious disease (Laws of 1894)

Villages shall not have the power to prohibit interments in any cemetery in their limits unless it can be shown that such interments are detrimental to the public health (Laws of 1889)

The erection and maintenance of crematories authorized, but their use prohibited nearer than 300 yards to any dwelling house without owner's consent (Laws of 1893)

No person is permitted to remove or convey a corpse for burial to or from any city, village or township, without a permit from the local board of health (Laws of 1893)

Rules of the State Board of Health prohibit public funerals in deaths from contagious disease, prohibit disinterment of corpse without a permit from that Board

Oklahoma Territory Rules of Territorial Board provide that no cemetery shall be located nearer than one mile of any town, city, or source of any public water supply or water works

Disinterment between December 1 and April 15 on permission of the local board of health indorsed by Territorial Board

Bodies dead of a contagious disease can not be disinterred until three years after burial unless the burial grounds in which they are placed should become a menace to public health, and then only by consent of local and Territorial Board and under supervision of the local board

Public funerals prohibited when death was due to a contagious disease

Pennsylvania Unlawful to bury the dead in land draining into any stream furnishing in part or in whole the water supply of any city Not applicable to land now used for burials (Laws of 1895)

Cremation of a dead body forbidden without a permit from the health authorities of the place where the body is cremated Permit only granted on presentation of death certificate from attending physician or coroner, signed by undertaker and person in charge of the crematory

Rules of State Board of Health prohibit public or church funeral in death from contagious disease Prohibit exhumation between May and October, and in case of contagious disease only by permission of and under conditions imposed by the State Board of Health

Tennessee No law on the disposal of the dead other than one prohibiting burial within municipal corporations or taxing districts containing 36,000 population

"Most cities and towns have ordinances requiring permit for burial " (Dr Lindsley, Secretary State Board of Health)

Texas "Burial regulated by local authorities Permit for burial required in every community " (Dr Swearingen, State Health Officer)

Vermont In establishing or enlarging burial grounds they must not be within twelve rods of any dwelling house, and remains must not be buried within twenty rods of such house (Laws of 1878)

Private burial required immediately after death of any person dying of Asiatic cholera, smallpox, typhus fever or yellow fever (Laws of 1892)

Rules of State Board of Health require private funeral where death resulted from a dangerous contagious disease

Virginia Cemeteries prohibited from being established within the limits of any incorporated city or town, or within 400 yards of any residence without consent of the owner

Washington Rules of the State Board of Health require interment within twelve hours after death in case of smallpox, and private funeral in all contagious diseases

West Virginia "No laws or regulations regulating disposal of the dead No permit for burial No special rules for prevention of contagion in connection with disposal of dead bodies " (Dr Baker, Secretary State Board of Health)

Wisconsin Cemeteries may not be established within one mile of any erected building within the limits of any recorded plot in any city or village, nor established outside any city or village within 200 rods of any inhabited dwelling in any recorded plot in any city or village, without the consent of the municipal authorities in such city or village (Sec 1454 Laws of 1887)

Certificate of death required of attending physician "Not enforced outside the city of Milwaukee" (Dr Wingate Secretary State Board of Health)

Rules of State Board of Health require burial within twenty-four hours after death when due to a contagious disease

Canada

Manitoba The Provincial Board of Health is authorized to provide rules for the safe and speedy interment of the dead, and conduct of funerals for the prevention of contagious disease

Attending physician required to notify the health authorities of deaths caused by a contagious disease

New Brunswick Rules of the Provincial Board provide for private funeral where death is due to a contagious disease Body to be disinfected, to be inclosed in a metallic or air-tight coffin which must not be re-opened Coffin not to be taken into any church

In cities and incorporated towns, permit for burial must be obtained, which is issued only on satisfactory statement of cause of death, etc

Nova Scotia No law on the disposal of the dead, other than ordinary cemetery regulations

No special rules of Board with reference to burial in contagious diseases

In city of Halifax, death certificate and burial permit required (Dr Reid, Secretary Provincial Board of Health)

Ontario There are no laws relating to the burial of the dead except those which govern cemetery companies, and those which relate to the burial of contagious corpses Proposed regulations for burial and transportation, are still under consideration by the Government (Dr Bryce, Secretary Provincial Board of Health)

Quebec Cemeteries located by diocesan authorities on request of their parishoners Must be as far as possible beyond probable limits of town or village, on elevated land inclining opposite to the town or village to prevent contamination of drinking water

Disinterment of dead bodies permitted on order of Judge of Superior Court, but not more than one body at a time, between June 1 and September 1

Where death is due to contagious disease, disinterment permitted only after five years, or such time as may be fixed by the Provincial Board of Health

Superior or diocesan ecclesiastical authority may prohibit interment in any cemetery or church

Bodies may be interred in church if coffin is covered with four feet of earth, or placed in stone vault eighteen inches thick, or brick twenty inches thick, disinfectants to be used in the coffin

Where death is due to contagious disease, church interment or vault deposit is prohibited Bodies must be in separate graves with four feet of earth over coffin In non-contagious diseases three feet of earth permitted Interment in private vaults—in contagious diseases—permitted if body is in hermetically sealed coffin

Provincial and local boards of health may prohibit dead bodies being taken into a church during an epidemic of a contagious disease on written permission of a local or diocesan ecclesiastical authority (Chapter XLVIII as amended)

Except in cases of suspicious cause of death, for which coroner's permit is required, all permits for disposal of the dead are given by the clergyman of the deceased's denomination (Dr Pelletier, Secretary Provincial Board of Health)

In the following States and Territories no laws could be found which in any way relate to the sanitary aspect of the disposal of the dead Alabama, Arizona, Arkansas, Delaware, Florida, Georgia, Idaho, Indiana, Indian Territory, Kansas, Kentucky, Louisiana, Maryland, Mississippi, Missouri, Montana, Nebraska, North Carolina, Oregon, Rhode Island, South Carolina, South Dakota, Texas, Utah, Washington, West Virginia, Wyoming

---

ON THE DISPOSAL OF THE DEAD, WITH SPECIAL REFERENCE TO THE PREVALENT PRACTICE OF EMBALMING

Read before the American Public Health Association

BY A WALTER SUITER, M D

Ex President Medical Society State of New York, Fellow of New York Academy of Medicine, etc
HERKIMER N Y

From remotest antiquity to the present time, topics relating to the disposal of dead bodies have been universally interesting No subject has been more carefully considered from all points of view, and yet it is not inconsistent with facts to state that no material advancement as to methods of preservation or final disposition has been made over those which were practiced more than twenty centuries ago Indeed, there is a growing belief in the public mind that to return to the custom generally in vogue previous to the Christian era (cremation), would solve many perplexing problems with which sanitarians are not unfamiliar

Anciently, in Egyptian countries where the surrounding atmospheric conditions were favorable, the dead bodies of human beings were embalmed and the mummified remains indefinitely preserved The Jewish nations entombed their dead in rock-bound receptacles called sepulchers In Greece and Rome the practice of cremation obtained, while it appears that we probably owe to the ancient Chinese the origin of the common method of the present date, viz that of interment or earth-burial

For ages this absorbing subject has been surrounded, modified and in various ways influenced among people of all classes, conditions and climes by vexatious questions relating for the most part to sentimental, religious, sanitary and medico-legal considerations

It will be the purpose of this paper, in the briefest manner consistent with intelligent description, to invite the attention of this body to some questions which have especial reference to the two last named considerations

According to early chronologic records, no branch of art was cultivated in higher degree than that of the embalmment of the Roman corpse Affection and superstition, always the greatest motive powers of the world, together with the prevalent fanciful ideas of death and subsequent everlasting life, all combined to give the greatest prominence to the extraordinary, elaborate, and costly methods which were employed in the remote periods of civilization for the preservation of dead bodies, in order that they might be kept uninterred As to means and methods, they were chiefly evisceration and cleansing, salting and bituminizing, the insertion in the emptied three great cavities of antiseptic balms and spices, desiccation by favorable atmospheric surroundings and the subsequent bandaging with expensive muslin and linen fabrics, painting, gilding and marking of the hermetically sealed cases provided for their final reception—all of which consumed a period of time amounting to seventy or seventy five days The final result of this process of mummification was to render the body as inoffensive in a sanitary sense as a block of wood or stone, and specimens of the remains of ancient kings and noblemen have been discovered and are on exhibition who lived and flourished at various epochs from 1,000 years before the time of Christ, when the opposition of the priests inhibited the custom and caused the complete decadence of the art and its consequent abandonment, until the discovery of the circulation of the blood suggested an easier, less costly and quicker method for the accomplishment of the desired purpose

The great anatomist and surgeon, William Hunter, in the latter part of the eighteenth century, practiced the injection of essential oils through the principal arteries for the preservation of anatomic subjects, but it was not until about the year 1835 that antiseptic solutions were used in this manner for the purpose of embalming, when the custom was inaugurated, simultaneously it is said, by Drs Lauth of Strasbourg, Franchini of Naples, and Gannal of France Various substances were then used, as chlorid and sulphate of alumina, arsenic, zinc and mercury—the preservative powers of which had been established Since that time to the present date nearly every substance known to have properties in any degree antiseptic when applied to animal tissues has been used for the purpose, and it would be quixotic to attempt the enumeration of the various formulas which have been from time to time proposed It is perfectly proper to state, however, that taking the customs and achievements of the people of ancient times in this regard for a standard, the modern practice of embalming has been steadily retrograding in skill and usefulness by being placed, without legal control or restriction, almost entirely in the hands of the ordinary undertaker, who is ignorant in most instances of the principles involved The practice of injecting the blood vessels has undergone of late a degenerative change As a consequence of the hasty and superficial manner in which this operation is now performed, circumstances are too frequently encountered which are a menace alike to the welfare of society in general and to public sanitation, and it is the special purpose of this paper to call attention thereto, with a view to securing the indorsement of this great and influential organization to the effort which has been and is being made in the State of New York to regulate the practice by legal enactment, to be followed, it is hoped, by every other State in the Union

I presume there are very few men of experience present who will not join me in asserting that the method of embalming at present in use by the so-called funeral director, is not worthy of the name It may be briefly described as follows theoretically, and practically, in some cases, one of the principal arterial branches of the body (usually the brachial near the elbow bifurcation) is exposed and laid open with questionable skill, and a variable quantity of one of the innumerable fluids (which almost invariably contain in composition one or more or all of the preparations of mercury, arsenic, zinc and carbolic acid) is pumped by means of a syringe into the artery, supposedly in a direction that the blood naturally flows

More often, and almost invariably in remote districts, this process is carelessly modified, so that the operation consists in simply pumping the liquids into the thoracic and abdominal cavities through a trocar, and also by means of rubber tubing into the rectum and *per oram* into the stomach It is supposed that the result of this is to preserve the body in a sanitary and presentable condition for ceremonial purposes previous to burial There is little doubt that if the proper injection of the blood vessels is carefully done with the required anatomic skill, such a result could be achieved with satisfaction, but it is obvious that when done in the incomplete and unscientific manner just referred to, the preservative effect is almost, if not quite *nil*, and if it were not for the ordinary precautions commonly practiced by the friends of the deceased themselves, the corpse would in most instances become a public nuisance in high degree before the final disposition

The growing tendency to this careless and superficial treatment on the part of the undertaker, without legal regulation to obviate it, is the doorway to an enormous and systematic deception—a commercial fraud, in fact, as a comfortable fee is charged for the service To illustrate, I will not attempt to burden my remarks by citing numerous examples, which might readily be done, but will simply mention one familiar case which is well in point, because it was an instance where inutility was abundantly demonstrated when every facility was offered and the conditions were unusually favorable I refer to the notable case of the late General Grant, whose lamented death, although for a long time previous an anticipated event, was a national calamity It would naturally be supposed that in such an instance extraordinary precautions would be taken to preserve the remains for the elaborate and extensively planned ceremonies incident to the occasion, and presumably the body was embalmed, and doubtless with the best skill obtainable A few days later, when the funeral train reached Albany on its way from Mount Macgregor to the final resting place at now famous Riverside Park, a countless multitude of interested and admiring people were shocked to observe that no semblance of the well-known features of the distinguished military chieftain was recognizable Suggillations, together with many other evidences of rapidly advancing decomposition, were apparent, in spite of the fact that diligent effort was made to conceal them There can be no doubt that the public health was in great degree endangered by the unpleasant circumstances

This is typically illustrative of frequent occurrences of the kind in common observation, and I am led thereby to feel justified in declaring that there is a strong argument apparent herein in favor of legislation of such a character as will lead, at least, to the modification, if not the prohibition of the so-called embalming process, which in a great proportion of instances neither accomplishes the intended purpose to prevent putrefactive changes with their attendant odors and appearances, nor properly conforms to the common principles in public health administration.

The other phase of this subject, to which I desire to call attention, might with propriety be said to deal rather with *public morals* than with *public health*, but it seems that no apology is due for the reference, as those two titles so closely merge into each other in practice as to suggest that the medico-legal aspect comes properly within the scope and purview of the fundamental principles of this organization.

A case which I here quote from one of my previous papers[1] will also serve as a type in illustration.

> Mr. E. A. P., a medicine vendor, aged about 75 years, a short time after marrying his third wife died with somewhat obscure symptoms after an illness of seven days. Some time after his burial, suspicion was aroused on the part of his relatives that his death was not the result of natural causes, and an investigation was instituted. I was employed by the authorities to exhume the body and ascertain, if possible, the actual cause of death. The body was found to be partially decomposed. The viscera of both the thoracic and abdominal cavities was carefully removed and properly prepared for subsequent chemic analysis, with a view to the establishment of the presence of poisons.
>
> The analysis demonstrated unmistakably the presence in the materials examined of arsenic, mercury and zinc in large and lethal quantities. About this time I was informed in a casual manner that the body had been embalmed by the undertaker who had charge of the interment and, upon inquiry, it was ascertained that such was the case. The body had been treated in the following manner. A so called embalming fluid was injected into the principal artery of both arms, and openings were made into the thoracic and abdominal walls through which a quantity of the same liquid was thrown into each of these great cavities. Inquiry was made of the manufacturers of the liquid as to its composition. They admitted that it contained in solution the chlorid of zinc and bichlorid of mercury, but denied the presence of arsenic in any form. A sample of the fluid was then procured and analyzed. The analysis revealed that it contained, beside other unimportant ingredients, the very salts and compounds found in the remains—those of arsenic, mercury and zinc—the revelation of, and testimony upon which, together with other suspicious facts were to be relied upon by the prosecuting officers to constitute the *corpus delicti* in the action. It was therefore impossible to determine whether these poisons were introduced into the body before or after death and, for obvious reasons, the case was dismissed from the courts in consequence, although after a subsequent careful re examination of the suspected tissues by cutting them into fine pieces and repeatedly washing them in chemically pure water until all traces of the poisons were lost in the washings, and the remaining substances after being dried and analyzed still showed the presence of the metals mentioned, thus indicating probable ante mortem absorption, no chemist would dare to express a positive opinion that, beyond reasonable doubt, the case was one of ante-mortem or post-mortem poisoning.

This is a striking example of cases which have been occurring in great numbers in recent years and are at present increasing in frequency. I do not hesitate to venture the opinion that there is no chemist of any considerable medico-legal experience who has failed to meet with similar instances, and the subject is now receiving the careful attention of many lawyers, judges, physicians, prosecuting officers and, to some extent, legislators, with a view to the enactment of such laws relating to the disposal of dead bodies as will insure proper protection in this respect and meet, at the same time, the requirements of sanitation, with due and proper regard for the demands of sentiment.

The menace to the welfare and safety of the public is apparent in the premises indicated in this case, and I feel sure that its various relations will be at once appreciated.

It seems that no one can fail to observe the opportunity offered herein, to a criminally disposed individual, to commit and subsequently cancel the crime of murder by poisoning—it simply being necessary that he should make sure that the body of the victim is treated in the manner referred to. That this opportunity is frequently taken advantage of at the present time is a well-known and indisputable fact among those of us who are concerned in such investigations, and I might consume the entire time of this session by reference to cases of such character which have come within my knowledge during several years past, and while the subject of relative legislation has been pending in my State.

Obscurity of symptoms leading to confusion as to diagnosis, lack of suspicion, together with the fact that the perpetrator is frequently able to control the extent and character of the medical attendance, the ease with which a careless and inefficient undertaker may be procured to make himself, unwittingly, a *particeps criminis*, all combine to favor the accomplishment of a criminal purpose, especially if it is the result of intelligent design as is generally the case.

It is a remarkably suggestive fact in this connection that between the years 1858 and 1892 not a single case of murder by poisoning was tried in the courts of the great city of New York. Is it reasonable to suppose that no such murders were committed in that city for a period of about thirty-five years? The statistics of London and Paris showed an average of three such cases yearly during that time. It will be observed that in consequence of this pernicious practice of embalming it is just as difficult to establish the *innocence* as the *guilt* of persons who may be accused.

By the toleration of the law, or the want of specific legal direction, this practice of alleged embalming has come to be an enormous offense to the public health and to certain other public interests, and the subject is worthy of the most careful attention. Ignorant men are taught, or teach themselves to believe, that the injection of a quantity of irritant metallic poisons in solution into the interior of the body anywhere is sufficient to effect preservation and secure their fee, and embalmment *secundum artum* is now practically fast growing to be a thing of the past in this country. Gallons of poisonous solutions are pumped into bodies indiscriminately, which are in an incredibly short time imbibed by other bodies in cemeteries, saturate, and are absorbed, by contiguous soils and streams, and also wells that are fed by subterranean waters which receive the percolations of graveyards filled with bodies thus treated. For example, a recent examination of the waters of Scajaquada creek which flows through Forest Lawn Cemetery in the city of Buffalo demonstrated the presence of considerable quantities of arsenic of the kind commonly used in the prevalent method of embalming.

In the belief that hasty treatment is necessary to obtain the preservative effect of the arsenical solutions, now universally employed, the undertaker, in the absence of proper legal requirement to the contrary, seldom awaits the issuance of the death certificate, and I am rarely called to make an autopsical examination that I do not find that his operation has preceded and in fact superseded mine.

The movement for the purpose of bringing about controlling legislation in these circumstances began in 1888 and was the outcome of a paper which the writer had the honor to read before the Medical Society of the State of New York. A bill with prohibitive provisions was introduced into the Legislature with the approval of the State Society, and its Committee on Legislation was directed to use all proper means to effect its passage. This bill was violently opposed by the State Undertakers' Association and persons engaged in the manufacture and sale of the objectionable solutions used. Although the praiseworthy object of the measure was so far appreciated by the legislators that it was passed in an unusually rapid manner to an advanced parliamentary standing, the opponents by superior political tactics succeeded in preventing its being placed upon its passage and it accordingly died, for that session, in the committee room. The public attention was attracted to the proposition, however, and favorable efforts were at once undertaken by many eminent persons who readily recognized the importance of the subject, including judges, health authorities, lawyers, chemists and physicans.

---

[1] Transactions Medical Society of State of New York. 1888.

Two years later, another bill was introduced in the form of an amendment to the penal code. This was not so sweeping in character as to the prohibitive restrictions of the former bill, but permitted of embalming by "the injection of any substance into the body only with the written consent of the attending physician and of the coroner having legal custody," prohibited "the injection of or placing upon the body of any solution containing arsenic, zinc, mercury or carbolic acid, except in cases of persons dead from contagious diseases by officers of boards of health, or for the preservation of bodies for dissection in legalized medical colleges."

This bill was actively advocated by a large number of the friends of the reform, and able addresses were made at the hearings by Professor Withaus of New York, Hon. Tracy C. Becker, the President of the State Bar Association, Professor Doremus, Hon. Clark Bell, Judge Brady and others. The bill was favorably reported by the committees of both Houses to which it was referred, but owing to the vigorous efforts of its opponents in the lobby it failed of passage, thus demonstrating once more the truth of the expression so familiar to sanitarians that "politics and science do not live upon the same street."

The measure has since been pending and it is understood that a renewed and determined effort to correct the evil will be made during the coming winter with great prospect of success, as the sanitary phase of the subject has become so apparent by the abuse of the practice previously referred to, that a general regulation of the disposal of dead bodies is believed to be most urgently demanded.

The fact that this Association has very pertinently established a standing committee for deliberation upon topics relating to the subject under consideration is regarded by the friends of this reform as a very favorable circumstance, as it is believed that all the associated important and vexatious questions relating thereto will be considered from all points of view, in connection with the work of the committee, and that without doubt the potent influence of this great organization may be secured to bring about the enactment of laws with uniformity of requirement, covering the preparation for burial, cremation and transportation of all dead bodies. These laws should have an intra-State, inter State and international character, and I beg to remark that the Association could not at the present time lend its powerful aid to a project of vaster or more salutary importance to the public weal.

I trust sincerely that I have succeeded by this hastily prepared paper in presenting the legislative part of my subject in a sufficiently comprehensive manner, so that the way may seem clear to a formal reference to the committee, with instructions to report a formula of indorsement to be acted upon by the Association at this meeting.

I have thus far said nothing concerning the innocuous substitutive methods which might be proposed to remedy the great evils which it has been the purpose of this article to expose. The argument most commonly advanced by the so called funeral directors in opposition to the passage of the restrictive acts proposed is that they should not be compelled to submit to the hardship of relinquishing the use of the arsenical fluids which have been depended upon so long, when no efficient substitute can be proposed. Every chemist present knows that such an argument can not be sustained. The truth is that it is the *cheapness* of these mineral substances in solution which chiefly recommends them for this purpose. These fluids are supplied for, not to exceed 30 cents per gallon by the manufacturers, and it is the interesting difference between the cost of one or two gallons hastily thrown into the mouth and rectum (as is now the almost universal practice of the ordinary undertaker) and the probable $30 fee that furnishes the motive for such an argument.

I am sure that every scientific gentlemen of experience in this audience will join me in the assertion that at least a score of substances might be mentioned as substitutes which have far greater preservative power than the mineral substances now in use. The cost would doubtless be greater in the case of most of them, but in view of the importance of the subject, the slight reduction in the profits of the undertaker would, I think, be tolerated by the public. Even this objection would in due time be adjusted by commercial competition and the relations of demand and supply. It must constantly be borne in mind, however, that no substance, whether miscellaneous or otherwise, would properly meet the sanitary requirements of the occasion that is not properly applied by its scientific introduction and distribution throughout the entire circulatory system of the body, and what is aimed at in the proposed restrictive law is to make it a penal offense to do anything short of it, along with certain specifications of the materials which shall be used.

It seems apropos to call attention at this point to a recently devised burial casket which is designed to meet some of the objections which can sanitarily be urged against most of the receptacles now made use of for transportation and burial. It is the invention of Dr. J. P. Hill, of Buffalo, and is constructed entirely of glass with a tapering circular opening at one end only. An end piece with grooved edges is fitted and made fast to the open end. In lieu of a description I will pass a perspective and diagram view of the instrument which I have obtained from the inventor, and which will convey an excellent idea of its apparent merits. The caskets will weigh from twenty to sixty pounds according to size.

It may be claimed for it, and I believe not extravagantly, that it is superior because it is cheap, light and durable, that it can be completely disinfected without trouble and can be made absolutely air- and gas-tight, that the body may be preserved for ceremonial purposes and transportation a reasonable time without embalming, that it prevents saturation of the soil and pollution of the atmosphere in the vicinity of cemeteries, protects the remains from action of soil, water, worms, etc , and that it may be cremated with the corpse

It appears that this would solve the problem presented by the paper of Dr Griffith at the Montreal meeting, as there would be no possibility of contagion from it and it is cheap enough to be within the reach of all classes

In conclusion, permit me to state that the principal propositions for which I contend in the foregoing remarks are as follows

1 That the scientific preparation of dead bodies has degraded in recent years, to the extent that the prevalent system as now carelessly practiced by the majority of undertakers is inefficient, and in many instances unsanitary

2 That it constantly leads to complications in criminal prosecutions, and entirely precludes the possibility of accurate medico-legal investigations—thus constituting a menace to the welfare of society

3 That salutary and non-complicating substitutes for the materials employed are available, and that thereby the abuse of the embalming process may be entirely and satisfactorily corrected

4 That the great importance of this subject merits the careful attention of this Association through its Committee on the Disposal of the Dead, and that proper legislation for restriction and control should be earnestly demanded in the interest of public sanitation and the public weal

A CASE OF QUADRUPLETS

BY FRANK A STAHL, M D

DEMONSTRATOR OF OBSTETRICS, RUSH MEDICAL COLLEGE, FELLOW CHICAGO GYNECOLOGICAL SOCIETY CHICAGO

A case of quadruplets occurring but once in 350,000 to 400,000 births, where there was no trace of heredity, where labor, with the exception of rupturing the membranes, was normal, where, notwithstanding the plural fetuses, none presented in a manner compromising the delivery of the other The interesting, theoretical, as well as practical study of such a case as a whole possesses sufficient intrinsic value to warrant even a superficial presentation of the case The case occurred at home under poor circumstances, unfortunately away from the advantages of a maternité and a couveuse, and was attended by a midwife I saw the case upon the third day

The husband, Patrick C , is a laborer, aged 32 years, a native of County Mayo, Ireland His height is 5 feet, 11 inches, weight 190 pounds Physically he is well developed There is no trace of multiple pregnancy in his line

The wife, Catherine C , is aged 33 years, a well proportioned woman, 5 feet, 8 inches in height, and weight 180 pounds, also a native of County Mayo There are no anatomic deviations apparent in her development, there is no trace of hereditary multiple pregnancies in her line Her previous labors, all normal, were as follows

1 - Para Partus maturus, child now 12 years old
2 Para Partus immaturus, child dead
3 Para Partus maturus, child now 8 years old
4 Para Partus maturus, died, 2 years old
5 Para Partus maturus, now 4 years old
6 Para Partus maturus, now 2 years old
7 Para Partus prematurus, the present quadruplets, all dead

Antelabor Period —She noticed with some degree of anxiety her unusually (for that period of pregnancy) large abdomen, but as she continued able to be about thought that things must be as they should be, though toward the latter days of her pregnancy she entertained some suspicion that there might be more than one intrauterine Also toward the last, a tendency to swollen limbs (pressure obstruction) was noticed, but never to any serious extent, otherwise nothing of any moment presented during the pregnancy On Monday, Sept 30, having just passed the eighth-month period of pregnancy, Mrs C accompanied her little boy to the dispensary to have a scalp wound dressed As the surgeon removed the dressings, catching sight of the bloody bandages and of the wound, she fainted and fell to the floor I could not elicit whether in falling she fell with abdomen to the floor or with back to the floor After recovering she made her way home, riding a part of the way That Monday evening and next Tuesday morning she felt very faint and tired, and toward Tuesday noon she experienced a slight bearing-down pain At irregular periods she continued to feel the slight bearing-down pains until the noon of Wednesday when, as she states, real labor pains commenced

The Labor —Wednesday, Oct 2, 3 P M, the first neonatus, vertex presentation, was delivered, the second, breach presentation, followed about 4 P M , the third, breech presentation, about 5 P M , the fourth, also breech presentation, following at about 6 P M With the fourth neonatus came the mass of secundines There was no hemorrhage of any consequence Allowing for the fear and dread of the parturient and the Teutonic excitability of the midwife under the circumstances, I gather from the description received from both mother and attendant that the deliveries were without difficulty and all spontaneous, with this exception that the attendant found it necessary to rupture each sac as it came down, stating that the membranes were unusually tough This toughness of the membranes and their artificial rupturing is often mentioned in the histories of these cases It would seem one of nature's methods of throwing around each fruit a greater safe-guard, a stronger protection than usual, to assist, perhaps, in preventing so far as possible a "conflict of the fittest"

The Secundines —As stated, they came away with the fourth neonatus as one mass The placental mass was made up of four small placentæ united by membranous tissue, each had its cord, and a characteristic amnio-chorionic membranal sac Unfortunately I could not persuade the midwife to disgorge the placenta, but the above is what I gathered from the mother and the attendant before the latter's cupidity was aroused

The puerperium passed without any noticeable feature

About four weeks' post-partum she attended mass, walking to the church Upon her return she complained of weakness and dizziness, followed, soon after she retired to bed, with a severe uterine hemorrhage, which was soon stopped The occasion offered me the coveted opportunity to examine the pelvis and uterus The examination yielded a wide, roomy, normal pelvis with a single normal uterus, at that time slightly subinvoluted, normal adnexa To day she is about and well with her 180 pounds, actively engaged in selling negatives of her quadruplets They are very poor

Observation of the illustration and a comparison of the figures show a perfect and singularly symmetrical development of the neonati Examination determined no abnormality in their development as malformation, defects, excesses, etc The three to the left, James, Patrick and Bridget, died the next morning between the hours of 9 and 12 A M Catherine, the little one, with dress turned under, was alive when the exposure was made, but died that evening about 78 hours post-partum They were all viable, and had I seen the case early enough I would have employed the couveuse, unfortunately, when I did arrive three were dead and the fourth moribund

5 That one or both ovaries may cast off a single or a double ovuled follicle at or about the same time

It is not difficult to conceive how, in the anomalous case, this latter unilateral or bilateral plural rupture of Graafian follicles may occur

As a determining factor in the development of pluriparous conditions, not only is the histological structure of the ovary, that is, one follicle containing one ovule or one follicle containing two ovules, of much importance, but also, I believe, and of not less importance, is the state of the sympathetic nervous system, since according as its sensibilities are, so will it reflect the exciting causes to which the organism may be exposed, and so proportionately in dignity will be the effect upon the ovary (and system generally) and its expression In the usual case there is but a single impregnation, but in the exceptional case, and this is not merely a conception of the imagination, the exciting agent may be so continuous and possess such activity as to call forth on the part of the organism an extraordinary expression—a *delirium eroticum*, as it were—during which, or soon following and induced by it, a maturing follicle or follicles is caused prematurely to rupture in the presence of one that has already ruptured and been impregnated, this second product of ovules is also impregnated, thus superimpregnation will have been occasioned

JAMES PATRICK BRIDGET CATHARINE

QUADRUPLETS, PARTUS PREMATURUS—EIGHT MONTHS

Neonatus	Name	Weight	Length	Cir O F	Lived
1	James	2.5 pounds	15 7 inches	10 75 inches	16 hours
2	Patrick	3 5 pounds	16 5 inches	11 5 inches	17 hours
3	Bridget	2 75 pounds	16 inches	10 5 inches	18 hours
4	Catherine	3 pounds	16 5 inches	11 5 inches	78 hours

Theory—Many theories have been advanced to explain the origin of multiparous pregnancies, and not a few ingenious ones too, in which it is readily seen that the imagination and fancy play quite a prominent rôle It would entail too great an expenditure of the reader's time and patience were the attempt made to present even a hasty resumé of the long list of theories extant It were best to be original, so far as possible, and leave the reader to pursue comparative research as time and inclination may desire

It is generally admitted that pluriparous pregnancies may obtain where any of the following conceded conditions may be present, namely

1 That one ovule may contain two germinal spots

2 That one Graäfian follicle may contain two ovules

3 That more than one follicle may rupture during the same ovulation

4 That ovulation, Graafian follicle rupture, may occur in the presence of pregnancy

Superimpregnation is the impregnation or fecundation of two or more ovules at one time, or about the same time, in contradistinction to *superfetation*, which is the impregnation of a second ovule when the uterus already contains an ovum which has arrived at a considerable degree of development That superimpregnation occurs in the exceptional case, there is no doubt The present case of quadruplets is such a case Its analogy occurs as the usual, the normal in some forms of the lower animals

That superfetation may and does occur is doubted by many, and especially by Auvard, who argues that it is only possible (a better word perhaps would be "probable," as all things are possible in nature) in a case of a double uterus or ectopic gestation From observations made in some of my own biparal cases, where there was no doubt as to the single character of the uterus, where gross inequalities in growth and development in the living as well as the dead would, among other considerations, strongly suggest unequal periods of continuity of existence, and in one case particularly, added to this evidence of the neonati, was the statement of the mother, a very intelligent woman, that she was afraid lest a pluriparous condition obtained as she had experienced that "caught feeling" a second time, a feeling not altogether one of pain and recognized by not a few women In view of such observations it would not be difficult to "believe in the reality of superfetation," contra Doléris This belief is further strengthened in the fact that "the same woman giving birth to twins bearing evident traces of being the offspring of fathers of different races" (Playfair), and again in the many illustrations that may be followed in the lower animals These views are strongly in line with the thought expressed by Darwin, who recognized what he so aptly terms "the similarity existing in all nature"

But to return to our quadruplets As brought out, heredity played no part as a causative factor, nor did a double uterus The case is one of superimpregnation, the impregnation of four ovules most probably at the same time, that is *simultaneous superimpregnation*, or, the impregnation of four ovules within a very short space of time, that is, *immediate successive superimpregnation*

As to the origin of the four ovules, either—(1) four follicles furnished each one ovule, (2) two follicles furnished each two ovules, (3) one follicle furnished two ovules, and two follicles furnished each one ovule they may have been expelled from one or both ovaries, most probably from both

That the quadruplets is a case of superimpregnation and that *four* ovules were impregnated is corroborated by numerous circumstances

By reference to the photograph and to the accompanying figures, it will be noticed that (*a*) the striking equality and symmetry of countenance, growth and development bespeak a common starting point, (*b*) the fingernails and length, which are of more importance than the weight in determining a case of this kind, are in each indicative of an eight months, as estimated by the mother, fetus, (*c*) there is a perfect formation of each fetus, there are no deformities of any kind, as malformations, excess or absence of toes, fingers, etc

By reference to the secundines, it may be noticed that though there was a single mass of placental tissue, it was made up of four separate subplacentæ, united by a membranous union, each subplacentæ had a single cord The mass of membranes was made up of four separate sacs with charactesistic amniochorionic membranal development To have four characteristic chorions there must have been four ovules, since the zona pellucida furnishes the external of the three elementary layers forming the mature chorion

Dear Doctor —Please direct the attention of your friends to *our* JOURNAL We will be pleased to send sample copies to any names you may suggest

INHERITED PECULIARITIES

BY J SANDERSON CHRISTISON, M D

CHICAGO

Physical features and moral and mental qualities of parents are so commonly observed in their children that nobody questions their being inherited, that is, they are recognized as "chips of the old blocks," and we are not surprised when the children bear an almost precise resemblance in every essential feature to one or other parent But when a parent has a peculiarity of a decidedly irregular or abnormal form which is passed to the child, or if it should entirely fail to appear, the question is at once raised as to how that happens, what laws explain the result We observe disease conditions passed to offspring as well as uncommon features, and which, if not strictly speaking inherited, are somehow due to the circumstances of birth It is not generally considered by the medical profession that diseases, as we commonly know them, are directly inherited, but that a tendency or special defect, a susceptibility or fitting quality is, and which renders the offspring all the more likely to be influenced by the peculiar circumstances of birth, especially the moral and physical atmospheres created by the parents and which give direction to the final outcome of disease and tending to carry them along the lines eastablished in the parents

But exactly what the fundamental law of heredity is remains unsettled, and probably will be so for some time to come, both from the lack of sufficient facts and the undecided question as to the limitations of a species But as like causes operating under like conditions must produce like results, it becomes evident that events, so to speak, striking the lines of growth and conformity at all angles of incidence and varying momenta, which, could they be measured, would express their resultant by a parallelogram of forces Everything in nature is under law, and all laws are mathematically precise

But to illustrate, we will represent some of the qualities or characteristics of parents by two groups of capital letters having numerals with + and — signs attached The letters will stand for a typical degree of a personal quality, or the amount that would balance in a well-proportioned individual, while the numerals will indicate how much above or below a typical degree the qualities are Thus, by taking a number of the same qualities, talents or peculiarities in both parents and combining them, the result will appear a compromise product in the offspring, as is illustrated in the quality of skin in the combination of negro and white, and which will have to compromise with its surroundings—its new environment Let the small letters represent particular conditions surrounding the offspring—forces in its environment and indicate by attached numerals whether they are favorable or unfavorable to the new combination and to what extent The accompanying example will indicate the problem

It will be seen in this example that neither parent has the same quality in the same degree, and that some qualities prominent in one parent are deficient in the other But a deficiency or condition below par is an abnormal condition, and if both parents have a deficiency of the same quality the offspring will have an intensified morbid disposition or a malformation The same rule will apply to qualities above par in degree, but the process of extension or reduction is limited both by environment and a self-limiting property—a specific quality essential in the specific group, the *number, nature* and *order* of properties in any living individual and by virtue of which the laws of affinity and association insure the preservation and continuation of specie character If this was not so there would be no limitation to divergence from type and no stability to organized forms But this theory, although one of special creation, does not clash with evolution in nature, but assumes that changes in the progress of nature have paved the way for the birth of a new form of life introduced in the course of cosmic progression and dated by an epoch-making catastrophe But the germinal essence—the differentiating and character-preserving power, although not produced or created by what we commonly regard as purely physical forces, is yet both made possible and conditioned by them In other words, a kingdom has been prepared for a king

c+2 = C Increase and favored.
d+13 = D Reduced but favored
e−11 = E Reduced and antagonized
f+5 = F Increased and favored.

But to return to our equation, which, though fragmentary, is representative as far as it goes, we may suppose the capital letters as each representing not one quality but a group of qualities supporting one characteristic, for owing to the interdependence of the parts of an organism this must be the case Then, as all qualities are represented by energies in their last analysis, and as energies have both transmutability and selective affinities, it is evident that the variations of environment in the course of development would have such an effect on the order of a group of qualities as would, to some extent, account for the rise or fall of an ancestral characteristic For example, $A+3$ representing the eye in the male as being rather better than common, and $A+20$ representing the eye in the female as being markedly superior to common we might expect the offspring to inherit eyes even superior to those of the mother, and which may be the case, but not always, for some will inherit eyes quite inferior This can only be explained by the fact that the eye represents many energies, part of which have become transmuted or transposed by selective affinity instituted by the new relations—the change of combination and other circumstances

Again, let $E+14$ represent a markedly superior power of reasoning in the male, and $E-15$ a markedly deficient power of reasoning in the female, we would naturally expect to find the offspring quite ordinary in this particular, but instead of which a superiority may result or even imbecility may appear But the power of reasoning depends more on the relative fullness of all the other qualities of the individual than on any one portion, so that the energies which give it basis are so numerous and varied that the influences of circumstances will be the least likely to affect this faculty

Having thus indicated how qualities are transmitted from generation to generation or apparently buried to reappear in a third or fourth generation, we may now notice a few of its practical illustrations If we glance at the various races of man we observe not only distinctions in physical forms but a prevalent or characteristic difference in moral and mental conditions, and we will also observe that those that have mixed most with the world, present the highest degree of civilization This would indicate that exclusiveness begets evils which preclude the attainment of the highest civilization The exclusiveness exercised by royalty in requiring its members to marry within a very limited circle of choice, is likely the cause why it has shone so little in the fields of science, art, poetry or invention, and for that matter statesmanship And this, notwithstanding almost all its members have been in the most favored position to exercise their talents under every advantage

Exclusiveness has illustrated its effect on the propagation of cretinism by increasing it most in those settlements most isolated from the world, and thus forcing inter-marriage But wherever these settlements have been opened up by the advances of civilization, cretinism has largely disappeared

Another marked illustration of the effect of exclusiveness was shown in the old village of Ines in France, and which was isolated by a barren territory and bad roads to such an extent as to compel intermarriage, and it is said that almost all the inhabitants had six fingers on each hand But after free communication was established with the outside world, this peculiarity soon died out in the subsequent generations Thus it is seen, that the principal of "Free Trade" in marriage is a safeguard against the deterioration of family stock and the only exclusiveness permissible with safety is that in the course of natural selection or in the just exercise of personal liberty

When we consider the persistence of qualities it is obvious that the racial or historic comes first, then community, family and individual in due order Many individual peculiarities inherited are very remarkable, as in the case of a slight accidental mutilation in a parent being represented in the same location in the child by a malformation But mutilations are rarely inherited, although malformations arising in the course of development sometimes are Defective eyes, slowly arising, are strongly hereditary, and it may be laid down, as a rule, that the closer the defective organ is associated with the brain the more likely is the defect, if it has been slowly acquired, to be transmitted in some form or other to the offspring One case will suffice to show how a constitutional defect in a parent will display itself in different members of the same family The mother had been confined to bed for several weeks with a peculiar nervous malady, but which was not correctly diagnosed until a physician from a distance was called, who was also requested to examine other members of the family—aged from 19 to 35 and five of them in all Their troubles were all chronic and quite different One had periodical headache, one had epileptic fits, one had spells of pugnacity, one had periodical neuralgia, and one had periodical attacks of gloom It was evident the main cause of them all was inherited defects, making different manifestations by virtue of a difference in the number, nature and order of experiences in the different individuals, and the conservative forces of nature had not been permitted to operate above the maternal level so as to eliminate the inherited evil

SOCIETY PROCEEDINGS

Chicago Pathological Society

Regular Meeting, Oct 10, 1895

Weller Van Hook, M D, President, in the chair

Dr Eliza H Root reported a case of

CELOSOMUS, VARIETY, SCHISTOSOMES RECOVERY

Celosomic fetuses are described as "Single monsters, characterized by a more or less complete eventration of the genito-urinary organs and various viscera The entire contents of the abdominal cavity may be found in a pouch, the walls of which are formed by the cord There are usually present in addition anomalies of the limbs, and the sex is usually female" (Charpentier) Charpentier, with Hirst and Pierson, follow Saint-Hilaire in distinguishing cases where the monstrosity is limited to the abdomen and cases where it extends to the thorax, and separates them into varieties

1 Aspalosomes where there exists lateral or median eventration at the lower part of the abdomen, the urinary, sexual and intestinal system opening externally by three separate orifices, the situation of which are not normal The genito-urinary organs are atrophied or absent Monsters of this variety, born alive, quickly die

2 Agenosomes where the organs of generation and urination are absent or rudimentary The anus is found in front where the external genitals should be Abdomen and thorax normal

3 Cyllosoma where there is a lateral eventration at the inferior portion of the abdomen and absence or lack of development of the pelvic limb of the same side

4 Schistosomes where there is lateral or median eventration throughout the entire extent of the abdomen, pelvic limbs absent or ill-developed The abdominal wall is replaced by a thin membrane through which the visceræ may be seen This variety is very rare (Saint-Hilaire and Charpentier)

From the available literature I find on the subject, I am inclined to think that modifications in degree of this variety are not so very unusual The case that it is my privilege to report I have placed under this variety as it seems to differ only in degree from the description of *schistosomes* The remaining two varieties, pleurosomes and kelosomes, involve the inventration of the thoracic visceræ, lateral or median, with absence of the thoracic limb on the cleft side Cases belonging to schistosomes I find reported under various headings Exomphalismus—"The whole contents of the abdominal cavity were outside the body" (Simpson of Edinburg) "The opening in the abdomen is about 1½ inches in diameter, and to right of cord attachment Through the opening protruded a sac, composed of amnion and peritoneum, and containing the intestines, liver and stomach" (Fritt's and Simpson a similar case) "The anterior aspect of the abdomen was covered by serous membrane only when "In both groins were a diminutive penis and scrotum" (Brown)

Ectopia abdominalis is a term under which several cases are reported, the descriptions corresponding with those under schistosomes "Abdominal cavity was open from sternum to pubes, the liver and intestines exposed and outside the body" (Kennedy) This author states other complications were present but does not particularize "There was a large tumor on the right side of the body, extending from the lower margin of the ribs to the crest of the ilium and from the median line in front to the axilliary line, and containing the liver, stomach and intestines" (Dr N Montgomery Jacobus reports a similar case) "Male born at full term, opening extended from epigastrum to left of iliac fossa, with protrusion of abdominal viscera" (Chas D Roe) "A case born at eight months, umbilical cord 2½ inches in length, protrusion of abdominal viscera complete, both feet clubbed" (Hawkins, Shattock and Herrigoyen report similar cases) Simple descriptions without any attempt at classification, characterize the reports of several cases, as 'A large tumor of abdomen, covered by a thin transparent membrane" "A tumor or opening extending from ensiform cartilage to within an inch of pubes, visceræ plainly visible" "The child presented a large eliptical opening three inches in length and two and one-half inches wide, through which protrued the whole of the small intestines, the stomach and right lobe of the liver" (Buchanan)

Matzdorf, of Berlin, reports one case as gastrocele, another as ectopia abdominale, and accounts for the abnormality as failure upon the part of the abdominal wall to unite, through the arrest in the development of the amnion and peritoneum A case of extrophy of the abdominal viscera in a phocomelus fetus is reported (John Collins) Three cases of extrophy abdominalis are reported in which the abdominal cavities were so contracted that reposition of the viscera was impossible (Stanton, Pichand and Laeconche) The children died soon after birth It is not stated if they were born at term or prematurely Extrophy abdominalis is not confined to single monsters Wands and Van Henkelen each report extrophy abdominalis in thoraceopagus, and Letitia Westgate a case of xiphopagus, born at the fifth or sixth month of gestation, which had a sac that contained all the abdominal viscera There was but one umbilical cord and the feet were clubbed This later case has all the characteristic s of a true schistosomus, except that it is a double monster

I find but few recoveries recorded one is a spontaneous recovery "A case of hernia of the abdominal wall, three inches in diameter, into which when the child cried a considerable portion of the intesties was forced The child lived and the skin gradually grew over the transparent covering" (J Tracy Simpson) Peritoneum in all probability lined the amnion in this case

"A tumor at the umbilicus, the size of an adult fist, containing omentum and intestines Parts successfully restored by operation" (Barton) Probably a case of hernia funiculi umbilici I find but two recorded cases of recovery The majority of the reports are silent as to recovery or death taking place Dorsett operated on a case unsuccessfully

In reviewing the cases that I find reported, incompleteness greatly mars their value for statistics or instruction in obstetrics But we do learn that other deformities of the body, other than the cleaving of the abdominal wall, are usual, that but few recoveries take place and only in cases where the opening is not more than three inches in diameter, that hydramnion is usually present, and delivery liable to be premature Dr Simpson, of Edinburgh, in the report of his case calls attention to several peculiar facts 1, labor premature, 2, altitude of infant, the trunk being curved backward and to the right side, instead of the normal forward curve of the body, 3, malposition, transverse, with presentation of the visceral mass One observer states that out of fifteen cases of exomphalismos (schistosomes) presentation of the abdomen was met with in thirteen Time of delivery not mentioned

In my own case labor was normal, time premature one month, with an uneventful lying in The mother, primipara, blonde, aged 24, entered the hospital in labor and was delivered five hours after entering by Dr Isabella Herb, interne Position, second presentation, vertex, occiput anterior The babe weighed seven pounds, fairly well nourished but debilitated The abdominal wall presented an eliptical opening, three inches in length by two and one half in width The cord was situated near the inferior left border of the opening, enclosed by the expanded end of the amnion of the cord No other deformity of the body appeared The kidneys and bowels performed their functions normally The child took the breast well but did not apparently gain in strength The temperature rose with the appearance of a ring of inflammation about the border of the cleft The abdomen became swollen and tympanitic, indicating the probable presence of peritonitis Beneath the transparent covering patches of lymph were visible The child was so weak an operation seemed unwise as it could only hasten the inevitable On the fourth day after birth, about the time for the normal falling of the cord, rupture of the membrane seemed imminent On the fifth day, when the dressings were removed in Dr D W Graham's surgical clinic in the woman's medical school, the dreaded event occurred The stomach, liver and intestines were protruding Dr Graham brought the edges of the opening together, after replacing the viscera, while the baby was under an anesthetic, as the doctor claimed "to make the baby decent for burial " The infant was returned to the hospital ward still sleeping On waking it took nourishment and early in the evening passed a loose, green colored stool Temperature 102 4 degrees F The day following, morning temperature 6 A M, 103 8 degrees F, M, 105 degrees F, 6 P M, 104 degrees F, after which temperature fell to 101 degrees F and then normal, varying from day to day, dressings removed on the fourth day after operation, all the sutures suppurating and part of them had pulled out of the tissues, evidently from tension The edges of the abdominal walls varied from one half to three eighths of an inch apart, space filled in with lymph stained with fresh bile, loosened stitches removed, wound cleaned with bichl hydrarg sol 1 2000, wound redressed with gauze and roller bandage which was soon stained through with bile[1] For several days the bile continued to escape freely and the child seemed in imminent danger of dying from inanition, the temperature, falling to 96 degrees and 97 degrees F Gradual contraction of the opening continued, and just as a fatal termination seemed imminent a change took place The bile flow decreased, the points of suppuration began to improve, the child rallied and progressed toward perfect recovery Twenty six days after birth and twenty one after the operation the child was dismissed from the hospital with instructions to return for redressings for supporting the weakened abdomen The opening was entirely closed, a linear scar one to one and one-half inches long remained The child grew well and strong and was soon lost sight of

DISCUSSION

Dr D W Graham—Mr President, I have just arrived and did not hear all of the report There is very little to say about it from my standpoint except that it is *one of those* cases that surprise us sometimes The case was brought to me in order that I might demonstrate congenital umbilical hernia to the class When the clothes were removed the intestines were lying on the surface of the abdomen The opening was very large At the time I regarded the case simply as one of congenital defect in the abdominal wall The intestines were soiled with fecal matter and urine and gathered up with dirty hands as there was no time for preparation They were restored within the abdomen with great difficulty and sutures inserted for the purpose, as Dr Root said in her report, "of giving the child a decent burial " That was the idea at the time, but I was glad to learn at the end of a week or more that the child was recovering

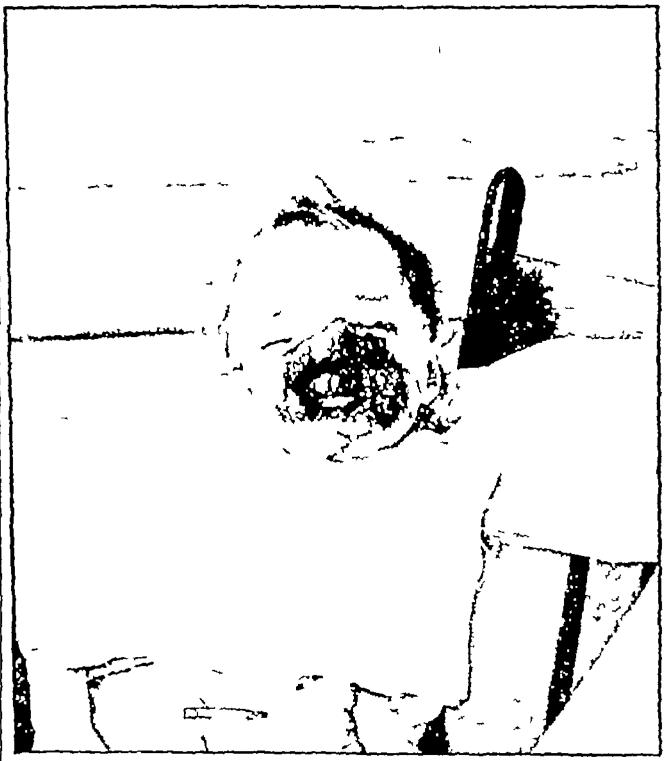
The opening required six or eight sutures, and before the last two or three were tied the abdominal cavity was flushed out hurriedly with warm sterilized water

Dr D D Bishop, Attending Dermatologist, and **Dr Lawrence Ryan**, Resident Physician, Cook County Hospital, Chicago, presented a paper entitled—

NOMA AND ALLIED DISEASES OF THE MOUTH A REPORT OF THREE CASES, WITH PATHOLOGIC EXAMINATION

The cases we have to report consist of one which was clinically noma, and two that belong more properly to the so called stomatitis ulcerosa The patients were brothers, all of whom had recently recovered from measles

Case 1 *Noma*—A S, male, white, aged 18 months, came to the hospital Feb 2, 1895 The patient was removed from the Home for the Friendless where, with his brothers he had passed through his late illness On entrance the child was considerably emaciated Skin milky-white, warm and dry Lies quietly on his back, eyes nearly closed A mucupurulent discharge escapes from the eyes Pulse very rapid, respirations shallow and accelerated Of most importance is the local condition, which is as follows The upper lip, tip and margin of the nose for a distance of one-quarter inch are covered by a thick, hard, black crust, which extends in a curved direction from the tip of the nose to the angle of the mouth on either side The lower lip shows no external evidences of disease The upper and lower left incisors and canine teeth are gone and the molars are quite loose The alveolar processes on the left side are denuded of gums and periosteum The sockets of the absent teeth are plainly visible Much the same condition exists on the right side The tissues of the *floor* of the mouth are gangrenous, but the tongue is not involved The soft tissues of the entire palate may be stripped off in shreds Upon removing the necrotic tissue more of the superior maxilla became visible, denuded of its periosteum The inter-maxillary suture was softened so as to allow of movement of the separate bones The lower jawbone was not involved but there were linear ulcers along the line of junction of the lip and gum The nasal septum was visible The necrosis advanced rapidly, so that at the time of death, which occurred forty-four hours after entrance to the hospital, nearly the whole nose, the cheeks on both sides to a point midway between the ears and mouth and a large portion of the chin were involved The temperature during this time ranged from 102 to 104 degrees F, pulse 150 to 160, and very weak, the respirations were



---

[1] I am unable to account for the discharge of bile There might have been some faulty development of bile ducts or injury to gall bladder

from 40 to 60 per minute No autopsy was permitted Some of the tissue was excised for histologic examinations, and cultures were prepared The treatment employed was removal of the necrotic mass, cauterization with strong nitric acid, and antiseptic applications were freely used , liquid diet and strychnin or other stimulants internally

Case 2 Stomatitis Ulcerosa—F S , male, white, aged 3 years Was admitted to the hospital Feb 25, 1895 General condition is that of a healthy child The patient had entirely recovered from measles about three weeks previously, but had suffered lately with sore mouth, accompanied by fever and general indisposition Examination of the mouth shows an ulcer one half-inch in diameter on the external surface of the upper lip to the left of the median line small linear ulcers are situated along the margins of the gums and incisor teeth, both superior and inferior , a round ulcer one-half-inch in diameter is seen beneath the tip of the tongue, and a small superficial ulcer on the inner surface of the left cheek, this is three quarters by one-half inch in diameter , a similar ulcer in the corresponding situation on the right cheek , the floor of all the ulcers is covered by a grayish necrotic slough , there is slight enlargement of the cervical lymphatic glands There was some elevation of temperature, rapid pulse and respiration for the succeeding four days, when they became normal and remained so Local treatment consisted of cauterization, cleanliness and the use of antiseptic washes freely applied The patient -improved rapidly and was discharged eighteen days after entrance entirely well

Case 3 Stomatitis Ulcerosa—C S , male, aged $4\frac{1}{2}$ years Entered the hospital March 2, 1895 Had been treated for measles and considered well four weeks previously The child seems quite well, except for ulcerations of the gums Ulcers are to be seen about the left lower molar teeth, and quite marked ulcerations about all the teeth on the left side of upper jaw The child suffered in no way, except for the local condition Under treatment similar to that employed with his brother recovery took place in the course of ten or twelve days

Cancrum oris, as defined by Starr,[2] is a gangrene of the mouth, beginning on the gums or the inner surface of the cheek, spreading with great rapidity and destroying every kind of tissue upon which it develops

The various authors who have written on the subject agree as to the nature of the disease, but show some difference of opinion as to the starting point of the affection Thus, Bohn,[6] Echorst,[4] Osler[3] and Ziegler say that noma of the mouth begins either in the mucous membrane of the gums or cheeks Billroth describes it as a gangrenous nodule beginning in the middle of the cheek, while Moullin says it sometimes begins in the mucous membrane, but more often in the submucous tissue near the orifice of Steno's duct Fagge[2] believes the gangrenous process begins in the inside of the cheek, always in the submucous tissue, and rarely starts in the gums

The different authorities differ again as to the relationship existing between ulcerative stomatitis and cancrum oris Bohn,[6] Keating,[1] Starr[2] and Osler[3] consider them under separate headings, while Eichorst[4] and Ufflemann speak of them as a single affection Bohn, however, distinctly says that ulcerative stomatitis may be the beginning of a cancrum oris

Predisposing Causes—Cancrum oris usually occurs in children between the first and second dentition Several cases have been reported of late, however, in adults[5] It is more often seen in hospitals and public charities than in private practice Eichorst speaks of it as occurring frequently in barracks Both sexes are attacked nearly equally Thus, Relliet and Barthez[6] report 183 cases, 63 of which were in girls

As to climate, it is seen most in temperate and cold-temperate regions, especially in the northern seashores It is not limited to the cooler localities, however, as Galloway[7] speaks of it as of frequent occurrence in Mexico, and cases have been reported from India It is said to be more common in large cities than in the country The cold and damp weather of spring and autumn seem to favor its development

More than one half the cases follow measles, but cases are reported of association with other infectious diseases, as pertussis, scarlatina, typhoid and typhus fevers It is often seen in association with malaria, particularly in the northern countries, Komorowski[8] having found the plasmodia in the blood of more than one-half of the twenty-three cases reported by him It is often a complication of diseases in which cachexia or marked anemia are present Finally, it is needless to say, that the disease is most frequently seen among patients whose surroundings are unhygienic and whose personal habits are uncleanly

As to the pathology of cancrum oris, the clinical picture speaks for a progressive inflammation and the histologic investigations seem to warrant this interpretation Bohn[6] describes the microscopic changes in the gangrenous tissue as consisting of molecular necrosis of the tissue elements, large or small drops of fat crystals, triple phosphates, derivatives from the blood, coloring matter and bacteria The bones die as far as the periosteum is destroyed , this is usually superficial, but at times the whole thickness of the jaw becomes disorganized The vessels are unaffected, except in the necrotic tissue itself, where they are thrombosed The vascular changes are therefore of a secondary nature The gangrene may remain dry but is usually moist The visceral changes are inflammation and gangrene of the gastro intestinal tract, pleuritis, lobular pneumonia and gangrene of the lung, hydrocephalus and thrombosis of the cerebral sinuses

The pathologic investigations of our cases consisted of cultural examinations, inoculations of animals and histologic sections

Case 1 Cultures—The cutaneous surface soon after death was burned, incised with a sterilized knife at the border of the gangrenous tissue, and cultures made from below the skin on 5 per cent glycerin agar-agar After incubating, the growth developed as a pure culture of an organism showing the following characteristics 1 In tubes kept at 37 degrees C , fine white deeply-situated colonies about pin point-sized were seen after two days. Though kept under observation for several days there was no increase in size above that described 2 White transparent superficial colonies, pin-head-sized, with a denser white pin point-sized area in the center Under low power these appear of deep brown color in center and grow paler and thinner toward the edge , the edges are finely dentated , the surface is finely granular and broken by fine lines and furrows radiating from the center

The growth on slant of agar-agar was white, shining, presenting a translucent surface and extended three sixteenths of an inch to the side of the line of inoculation The edges were irregular, being both finely and coarsely dentated The organisms as seen in the hanging drop were rather short bacilli, non-motile and were frequently seen lying end-to end The were often collected into small clumps and but rarely single

Staining Properties—With gentian violet anilin water these bacilli stain uniformly and intensely The ends of some are pointed, while others show an expanded (pear shaped) end , others again are curved With Loeffler's alkalin solution of methylene blue they stain more intensely in segments, the ends usually more deeply and the central portion faintly Gram's stain was also successful

The growth on slants of 5 per cent glycerin agar-agar showed fine white globules size of a large pin head and becoming slightly confluent The organisms reacted to stain in a manner identical with those described from plain agar-agar On gelatin at room temperature a very slight white growth appeared which caused no liquefaction Bouillon was rendered cloudy in twenty-four hours at 37 degrees C , while the growth settled to bottom of tube after forty eight hours Potato inoculations showed an almost invisible growth Litmus milk gave no perceptible change in color no coagulation There was no gas production with glucose and lactose agar

Cultures on Loeffler's blood serum mixture, kept at 37 degrees C , gave a white growth in twenty-four hours Preparations stained with Loeffler's alkalin solution of methylene blue showed bacilli larger than those from the cultures on agar-agar with pointed or rounded ends, often irregular in form and staining irregularly The individual and staining popularities were exactly like those of the diphtheria bacillus grown in the same medium

Inoculations—1 A rabbit, two-thirds grown, was inoculated subcutaneously at the base of ear with 4 c c of a two days' old incubator culture in bouillon The only noticeable effect was slight swelling for twenty four hours

2 A full-grown guinea pig was inoculated subcutaneously in the abdominal wall with $1\frac{1}{2}$ c c of a forty-eight hour old bouillon culture , some local swelling followed and the animal was sick for two or three days Recovery took place quickly and the animal remained well As the pig was old and therefore less susceptible to the diphtheria bacillus the degree of virulence, if we are dealing with that organism, was necessarily hard to determine

Case 2—Surface cultures from the ulcers showed a bacillus which was in all its morphologic and cultured popularities the same as that described in Case 1 Cultures made on Loeffler's blood serum mixture corresponded, as did those in Case 1 in every way morphologically and in staining properties to the diphtheria bacillus Besides this organism the staphylococcus pyogenes aureus was present

Inoculations—A guinea pig weighing 520 gms received subcutaneously in the abdominal wall 3 c c of a twenty four hour old incubated bouillon culture Aside from the production of a local swelling and being sick for a few days no effects were observed

Case ,—Inoculations on cultures taken from the surface *of the ulcers several days after the local antiseptic treatment* had been instituted gave only the staphylococcus pyogenes aurens, and the staphylococcus pyogenes

Hystologic Sections—A piece of the buccal wall from the case of noma was removed just after death, cut so as to include some of gangrenous and adjacent normal tissue, partially hardened in Möller's fluid, finished in alcohol, coated in colloidin and stained with hematoxyllin and eosin Examined with the low power the greatest extent of necrosis is seen to be on the mucous surface, here the epithelium appears as a granular mass staining deeply with *eosin and* showing only a few fragments of nuclei, the submucous connective tissue, muscle and mucous glands are seen as necrotic remains, also diffusely stained with eosin Here and there, both upon the surface and deeply seated in the necrosed tissue, islands of irregular shape, staining with the hermatoxyllin are seen, these, under high power, appear to be made up of *microörganisms* The necrotic zone is succeeded by tissue more nearly normal, and just at the border *line between* the two zones there is an extensive leucocytic infiltration As one observes the border of the section away from the point at which there is absolute necrosis it is noticeable that the superficial epithelial cells are entirely gone as deep as the retemucosum, while at a greater distance the loss is *less and less until finally*, at quite a remote distance the normal layers of cells are preserved Corresponding *with this* gradual distruction of the superficial epithelial layers the migration of leucocytes becomes less and less as we pass away from the necrosis The blood vessels are dilated and often plugged with leucocytes

Sections stained by Gram's method showed deeply situated *in the necrotic zone* numerous bacilli quite closely packed together These organisms are about twice the length of the tubercle bacillus, rather slender, thicker in the middle portion than at the ends The ends are rounded *in* some instances, but pointed in others The bacilli appear like a pure culture and *stain best just at the point where* the necrotic zone blends off into the inflammatory tissue Sections stained *with Loeffler's* methylene blue shows a bacillus in the same situation and morphologically the same On the surface of the necrotic border some of the same organisms are seen and in addition numerous large bacilli and micrococci

The observations *concerning the essential* etiology of noma have been few Up to quite recent times but little was done toward determining the real cause, the conditions which favor its development alone being described Bohn[6] in his classical description of the disease describes many bacteria in the sloughing border but assigns *no* special significance The authorities to-day are inclined to the belief in a specific cause at *work upon* a well prepared soil The frequent occurrence of the disease in public institutions and the apparent preference for localization upon the mucous membranes of the different openings of the body suggests a *microbic* origin

Previous to Lingard's[9] contribution to the *subject in* 1888, no definite organism having anything like a constant relationship had been described He *found* an extensive growth of a thread like organism 4–8 micromilimeters long just at the line of extension of the necrosed tissue Cultivations and subsequent inoculations into animals gave rise to appearances precisely similar to those seen in the original disease, and in the heart muscle necrotic foci and *clusters of* a thread-like organism with a surrounding inflammatory zone were discovered The intermuscular *fasciæ* were also infiltrated with the same bacterial growth None were found, however, in viscera of the *human* subject dead from *noma* Lingard recovered this organism in all of his five cases He claims an identity between it and one found in ulcerative stomatitis in calves

Schimmelbush[10] previously described an organism quite like the one seen by Lingard, found in the same *situations*, which grew on gelatin Inoculations in rabbits gave rise to abscesses In 1890 Grawitz[11] found in sections at the line of living and dead tissue many bacilli which grew out into long threads The absence of micrococci and thick bacilli, which are usually seen in such necrotic tissue when exposed to the air, made it appear to him that only a single species of organism was at work No cultures were made Loeffler, *in discussing Grawitz's paper, remarked that the microscopic picture, including the zone of organisms* resembled that seen in mouth diphtheria of the calf

Masterman[12] in 1891 found micrococci in the lymphatics of one of his two cases Cornil and Babes have found short *streptococci and rods, and Ranke found the same strepto*coccus described by Koch as producing progressive necrosis in field mice Rabbits in which tissue was implanted, died

Bartels[13] in 1892 described in one of his two cases a slender bacillus in the gangrenous tissue and at autopsy the same organisms in the kidneys, lymph glands, spleen and heart muscle These stained with Loeffler's blue and showed spore formation

In 1893 Elder[13] found long bacilli running to a point in the tissues, cultures were unsuccessful, and Barnabei[14] found the staphylococcus pyogenes aureus in a case of *noma* with septico pyemia Foote[15] in the same year made bacterio*logic examinations from the surface of sloughing* tissues in a case of cancrum oris but only micrococci were found He implanted pieces of the slough into the subcutaneous abdominal tissues of rabbits, but in the abscess formed only the ordinary pyogenic organisms were found The animals recovered His sections made from the skin covering the malor bone, showed numerous bacilli measuring 2½ to 3½ micromillimeters often joined end to end and in long strings, situated just at the border of the necrotic zone, next to the inflammatory zone Cover glass preparations from the surface of the slough showed micrococci and a few bacilli The blood in his case was that of an ordinary secondary anemia

Siegel,[16] in 1894, in an article entitled, "The Identity of Cancrum Oris in Man, and Hoof and Mouth Disease of Cattle," describes a short bacillus, (0 5 to 0 7 *microm*) This organism stains deepest at the ends, is immotile, and grows on gelatin without liquefaction It also grows on potato, blood serum and bouillon Gram's stain was unsuccessful It was pathogenic to doves, cattle and pigs

Sansom,[18] in 1878, described certain moving bodies *in* the blood of a girl aged 4¼ years, the subject of noma These were granules and numerous small refractile bodies, showing rapid locomotion and resembling octahedral crystals They were most numerous at the height of the temperature and became aggregated into zoogloea masses Sansom did not find these in all the cases and he is inclined to believe the bodies were non-virulent organisms growing in the blood derived from the gangrenous area Osler thinks they were bloodplates Morse[19] has confirmed Sansom's observations No etiologic significance can very well be attached to these bodies

Reviewing these reports then, we find the most constant organism and the one to which the most presumable etiologic importance may be attached is a long bacillus growing in threads and end-to end, deeply situated in the necrotic *zone, near the* unaffected tissue In Lingard's five cases these were recovered in the cultures, proved pathogenic to rabbits and again found in the tissues of the dead animals Schimmelbush also cultivated his on gelatin and produced abscesses in rabbits Foote's cultures were all unsuccessful but the organism described by him located in the tissues seems quite similar to those of Schimmelbush and Lingard

Cultivations were also successful in Siegel's cases, but the organism differed from the others in being much shorter Cultivations were unsuccessful with the other observers The organism recovered by us in cultures, certainly presents all the characteristics of the diphtheria bacillus except its effect upon guinea pigs, *to which it* was only slightly virulent Objections might be made, therefore, to calling it the Löffler bacillus *While* there is good reason for such objection, the organism corresponds as closely to all the requirements as do those that have been found in throats of patients either having a pseudo-membrane or in which no clinical evidence of diphtheria were present, which have been described as "diphtheria *bacilli* with reduced virulency" The absence of the pseudo-membrane should in no wise be held as against the presence of the diphtheria organisms, for have not diphtheria bacilli often been found in situations where the deposit was entirely absent? We therefore feel justified in placing our cases upon record as additions to those such as lacunar tonsillitis, fibrinous rhinitis, otitis media, vulvitis, glossitis, *gingivitis*, and wounds[20] in which diphtheria bacilli were found, but lacking in clinical appearances

As to the morphology of the bacilli found in the tissues, one can only say that they resemble the diphtheria organism as generally seen in exudates

There would seem, therefore, to be no similarity between the organism found in cultures and tissues by us and those described by other observers For they on the one hand, found bacilli growing in long threads and end-to end, while those seen by us were short, straight, curved and pear-shaped In considering this apparently wide difference one must not forget the wide range of forms taken by the bacillus diphtheriæ as one observes the growths upon different media and under different degrees of temperature Further, Klein[21] has demonstrated the diphtheria bacillus growing in long threads with granular swellings and knob-like terminals in the tissue of a cow inoculated with human diphtheria bacilli He also observed all the stages of development from the ordinary forms as usually seen, up to the long thread-like forms These observations of Klein may be looked upon then at least, as evidence that the organism in tissues may assume a growth similar to the thread-like filaments found by Lingard and others These facts will scarcely warrant any conclusions as to the identity of our organism with those of other observers, but might be looked upon as a possible connecting link between those widely different forms

We can not refrain, in conclusion, from drawing attention to the probable identity of cancrum oris and ulcerative stomatitis Such a statement seems warranted by the observation of three cases all in the same family, following the same disease, showing distinctly different grades of development from the mild ulceration to profound gangrene, and in two of these the demonstration in cultures of the same organism

We wish to thank Dr George H Weaver for all of the bacteriologic examinations, also Dr J W Walker for photographs of the fatal case, and Dr E H Ochsner for clinical notes on one of the cases of ulcerative stomatitis

DISCUSSION

Dr Ludvig Hektoen—I desire to call attention to the great similarity between some lesions described in connection with noma and what is observed in connection with true diphtheria of the skin, of which there are now several undoubted cases on record, in which the diphtheria bacillus has been demonstrated by means of cultures and animal experiments

The Doctors' Club

At the regular monthly meeting of the Doctors' Club of Chicago held at the Chicago Beach Hotel, Oct 25, 1895, the subject discussed was " the Dispensary Evil "

Dr Marcus P Hatfield presided and introduced the guest of the evening, Prof Geo A Coe, Professor of Philosophy in the Northwestern University He spoke on " The Ethics of the Free Dispensary "

Dr Fernand Henrotin followed on " The Value of the Dispensary to the Poor " He dwelt upon the necessity of organized effort to furnish medical treatment and advice to the indigent and took the ground that the remedy for the evils of dispensaries lay in each physician taking care of his share of the poor of his neighborhood

Dr Edwin H Dorland spoke on " The Injustice of the Dispensary "

Dr F A Davis followed on " The Value of the Free Dispensary as a Clinical Instructor " He said that the student must get clinical teaching, and, since the Cook County Hospital's wards were closed to students, as also those of many other hospitals, the dispensaries filled a want in the line of education He estimated, judging from letters received from members of the staff of the West-Side Free Dispensary, that the proportion of persons treated who were able to pay was less than 25 per cent

Dr N H Cazier spoke on the subject, " The Dispensary's Robbery of the Poor "

Prof C R Henderson, of the University of Chicago, an invited guest, spoke on " The Relations of Dispensaries to Other Charities "

ETHICS OF THE FREE DISPENSARY

By **George A Case**, Ph D , Professor of Philosophy in Northwestern University

The ethics of the free dispensary involves four particular, if not distinct interests

1 The interest of the poor
2 The interest of the physician who gives his services
3 The interest of the physician whose income may be reduced through competition with the free dispensary
4 The interest of medical science and education

Any attempt to adjust so various, complicated, and apparently conflicting interests is certain to fail if it proceeds from the standpoint of any one of them alone We must, if possible, discover a higher standpoint from which to discern whether there be any unity of interest underneath this diversity This higher point of view is suggested in the conception of the unity of life with which the doctrine of evolution has made us familiar Just as, in order to understand any species, we must consider it as a member of a series embracing all forms of life upon our planet, so in morals, we find the meaning of a particular life on the function of a particular class only as we grasp the connection of this one with universal humanity Reflection upon life very soon convinces us that no man liveth unto himself and no man dyeth unto himself The man who conceives himself as the sole end of his functions conceives an idea as unmanageable as that of fixed and changeless species For we are all creatures of the social conditions in which we are born, grow up and functionate For we [illegible]e all products of the race, and, whether we will or no, the products of our activity return to the race for its enrichment or its impoverishing From this it is but a step to the conclusion, though of course the grounds can only be hinted at, that we are truly moral individuals only so far as the life of humanity advances toward the goal of its development This relation of the individual to the species is brought home to us chiefly in what we call society—in the municipality, State or other civil organization, and in the accepted customs of the people among whom we dwell It follows, therefore that *the special function of the physician is to apply his specialized knowledge to the advancement of the civilization of which he forms a part*

This principle has direct application to the question in hand In the first place, it determines the proper attitude of physicians toward one another as one, not of personal rivalry or selfish compet tion, but of friendly coöperation for the attainment of a social good At the same time, since the physician is an organ of the social life, he himself must be maintained in the condition of greatest efficiency It would be folly to educate men for the profession of medicine and then starve them, equally so to hinder their professional development at the very period when they are most capable of growing We need not question the wisdom of letting them win their spurs As Mr Emerson says

> " Cast the bantling on the rocks,
> Suckle him with the she-wolf's teat,
> Wintered with the hawk and fox,
> Power and speed be hands and feet "

Nevertheless this process may be made so painful as to interfere with efficiency, and this, plainly, would be unjustifiable It is in every way for the interest of the medical profession to maintain the dignity and promote the development of its own members

In the second place, our general principle sheds light upon the claims of the poor for free medical service The medieval idea of charity was that of indiscriminate giving It is well illustrated in the Legend Beautiful of Longfellow

"It was now the appointed hour,
When alike in shine or shower,
Winter's cold or summer's heat,
To the convent portals came
All the blind and halt and lame,
All the beggars of the street,
For their daily dole of food,
Dealt them by the brotherhood"

Whether this description could be applied to a modern free dispensary, I leave you to decide In any case, however, such charity is of the kind that covers a multitude of sins against society Sympathy unguided by reason or correct social ideals is as bad as liberty unregulated by law For each of these tends, in its own way, to create a class which supports itself by preying upon the rest of society

True charity, without forgetting the value to both parties of direct, sympathetic contact of a man with his neighbor, asks, first of all, what will promote soundness in the social organism as a whole The relation of social classes is not unlike that of the organs of the body, the heart requires food from the stomach, and the stomach requires blood from the heart, and yet, after all, it is not the particular organ that makes the demand, but rather the organism in its entirety and unity Similarly, the claims of the poor upon physicians neither originate nor terminate in the poor themselves, but in the need for social soundness and development While this implies that the physician's personal desires are to be subordinated to the common good it does not imply that he is to be at the beck and call of persons incapable of appreciating the cost of knowledge and skill The poor and their philanthropic friends have no more claim on a professional man's time than they have on that of a business man And yet I fear that any hesitation, at the demand of so-called charity, to scatter indiscriminately abroad the product of years of toil and study, while it would be commended in the merchant as business sense, would be condemned in the physician as selfishness or lack of sympathy Wise unselfishness requires that charity be so dispensed as not to increase but rather to remove the need for charity To love the poor is not merely to heal their diseases, but also to find and remove the causes of the same, not merely to give them things, but also to develop them toward physical and moral independence, not merely to keep them alive, but rather to show them how to live The free treatment of persons able to pay seems to me utterly indefensible I do not see how it can fail to pauperize them, or at least weaken their moral stamina If they can not pay the ordinary fee, but can pay something, do not destroy their self respect by assuming that they are already paupers

Moreover, the danger in merely giving is doubled when charity is administered in a purely official, impersonal manner It may be that diseases can be cured by machinery, but surely something more than machinery is necessary to develop the dependent classes into self-respect and self support Charity must be so administered as, while relieving present needs, to awaken manly and womanly feelings, and inspire with worthy hopes and ideals And who has so good opportunity for doing this as the physician? His relation to the patient is intimate and confidential, and this of itself opens the way for mutual sympathy and good will Then, too, the physician touches the moral life of his patient at its basis or substratum, for we need not hesitate to admit the implication of evolution, that the spiritual life waits for the physical organization, and that physical perfection is a condition of spiritual wholeness To be complete men we must be perfect animals There is moral value, then, in obedience to the laws of health The patient who coöperates with his physician in the effort to attain physical soundness is already on the road to a self-respecting moral life The personal relation of the physician to his charity patient is therefore of the utmost importance both to the patient himself and to society Here the earnest practitioner can stimulate the nerve of social progress, but when medical charity becomes merely official, merely professional and technical in the benightedly narrow sense of those terms, then it fails of much of its social effect—it is charity with its most charitable part left out

This brings me to the interest of medical science and education in the free dispensaries This is a delicate point, for science is jealous, and rightfully so, of all her prerogatives I yield to no one in point of loyalty to her and her demand for independence, purity, and the payment of all that knowledge costs Neither pity for the pains of a few frogs and guinea pigs, or even an occasional man shall hinder her progress If it is really necessary for her advancement that young practitioners should be deprived of a few patients, let these practitioners make the sacrifice gladly upon the altar of science and philanthropy

But is it not just possible that the sciences may be in danger of becoming fetishes? That our devotion shall lead to undervaluation of pain, undervaluation of social interests, and an abnormal demand for material for experiment and demonstration? Let us not forget that the sciences were made for man, not man for the sciences As the philosopher Kant said, we should treat humanity in the person of every man, never as means merely, but always as an end

Now, so long as patients are human beings and physicians also human, physicians must have a thought for some thing beyond the bodily mechanism They must think of the humanity of their patients and of all other persons concerned You will never succeed in putting the professional part of a physician into one pigeon hole and the human part into another, or, if you do, you will have brought forth a monster

Shall medicine mix itself up with morals, then? Not with the disputes of ethical theorists, to be sure, yet how blind should we be if we beheld naught of the social mission of every science, particularly of sciences like medicine, which have direct practical application The obligation to further the ends of social evolution pursues us whithersoever we go If we ascend into the heaven of religious contemplation, it is there if we make our bed in politics, behold it is there, if we take the wings of the morning and fly to the uttermost parts of commerce, even there doth it find us, if we say, Surely the seclusion of the study and the specialization of science shall hide us, even our science becomes a light about us to show us our duty The science of medicine, let me repeat, is a function of social life, and its end the furtherance of social evolution

But you will say, You have not yet told us how to reconcile the four clashing interests No, I have not done this, and shall not attempt to, for my purpose is not to devise ways and means, but only to put into clear light the ethical principles involved I bear, however, the optimistic conviction that whatever ought to be done can be done, and that this body of representative physicians, if agreed as to the social mission of their science and skill, will be able to execute that mission without sacrificing the real interest of any one

THE RELATIONS OF DISPENSARIES TO OTHER CHARITIES

Abstract of remarks of C R **Henderson**, Professor of Sociology, University of Chicago

Most delightfully and clearly has my colleague, Prof Coe, laid down the fundamental principles which bear upon this discussion And both of us gratefully acknowledge our debt to the physicians whose practical applications of these principles, out of a rich technical knowledge, have been extremely suggestive to us Personally, I thank you for the opportunity of bringing before this body of men, representatives of a profession whose service is a ministry of goodness, the organizing work of the Civic Federation in the field of relief and prevention Your interest and sympathy will be an important factor in the success of this measure

The action of the Civic Federation in sustaining the work of the Bureau of Charities assures its existence, but only a very general coöperation will insure its adequate and permanent triumph Only very slowly does this conception of democratic fellowship in contrast with aristocratic patronage take root in a vast community Customs of conduct and habits of mind have a momentum and an inertia which are only slowly modified

And yet, you gentlemen have for years expressed your conviction based on daily contact with the poor, that a vastly deeper and broader social work must be done if we are to do more than merely mitigate and palliate the awful course of pauperism In this great service of anticipating the misery of poverty, and employing prophylactic measures, all classes, and not the rich alone, must unite for a long, costly and patient campaign Our city charities tend to separate us from the poor and widen that chasm between classes which threaten to swallow our civilization

Justly, and not in vain, we turn to the medical profession for help in this work We do not compete with any of the numerous relief societies We are the friend of all beneficent agencies which are honestly and efficiently managed, and in no sense their rival The city of Chicago, it is asserted by authorities, spends $2,000,000 a year through about 200 agencies, public and private If any of you were building a house costing $38,000,000 whose annual expenses would be $2,000,000, you would not think 1 or 2 per cent fee for architect and superintendent would be excessive When we consider the interests of happiness and misery which are at stake we shall be all the more anxious to see that public relief does as little harm as possible, and that the vicious stream of causation in social conditions be stopped near the fountains Only a deep faith in principles and large social forces can lift us out of the alms-giving rut of ages and enable us to believe in measures directed against the very primal sources of misery We solicit your membership, your support, your counsel, and we shall be grateful for the continuance of your confidence

THE DISPENSARY'S ROBBING OF THE POOR

BY M H CAZIER M D

Mr Chairman and Gentlemen I have been edified by the remarks of the gentlemen who have preceded me in paying respects to the "Free Dispensary" as it is, particularly so by the remarks of Prof Coe I want to thank him now, both for myself and for the Club, for his very able presentation of the subject from the ethical standpoint It must, however be remembered that it is the province of ethics to point out the ideal for which we should ever strive but can never attain, because of the imperfection of means True to this principle, therefore, Prof Coe has admonished us to "aim high" very properly, for in the language of the agrarian philosopher, "if one don't hit the bull's one may make a pretty good shot"

It now remains to present my cause to the jury, and as may have been anticipated it is none other than an indictment for *grand larceny* I would not have you assume the prerogative of a court of last resort, and that our mind and thinking shall be the dictum by which others *must* be guided Yet if it shall appear that the poor are being robbed under the guise of charity, and if it shall be brought home to the door of the medical profession that they are fostering a cancer which is preying on the life blood of society, then, gentlemen, we can not escape responsibility It is therefore highly important that we, now and here, realize our obligations—yours as jurors, my own as an advocate to the end that truth shall prevail, and that we "render unto Cæsar the things that are Cæsar's, and unto God the things that are God's" As medical men we have a knowledge of the facts, each one of us has an abundance of testimony, but it is not in the capacity of physicians that we are to decide public questions—questions which have to do with the welfare of society As *witnesses* you are *physicians*, as *jurors* you are *men*

If we mistake our obligation and think and act only as prompted by professional instincts, actuated by the first law of nature, and recognizing no higher obligation, we descend to the level of the city alderman who asks, "What is there in it for me?" And as a profession we must remain hopelessly divided, for those of us connected with dispensary work and aided by its emoluments, will defend it, with all its vileness, while those not so committed will demand its unconditional abatement It is upon a higher plane, therefore, than thoughts of self aggrandizment can place us, that the demands of the hour require us to act Gentlemen of this Club, much as I value the distinction of being a *physician*, much more do I esteem the privilege of being a citizen of this city and of this commonwealth of States, much as I respect a *doctor*, a thousand times more do I respect a *man* It is in the light of the intelligence of the physician shorn of his selfishness and prejudice, and supported by that manhood which is awake to our obligations to society and to the State, that I ask you to look with me at the side of this question which deals with the subjective influence on the recipient

Let us, therefore, banish from our eyes the glaucoma of sordid greed and look broadly and see if possible the whole truth Competition for dispensary patients, between the various medical colleges and private enterprises of those not favored with college-teaching positions, is so fierce that advertising in its various guises is resorted to to attract people to the places where '*distinguished physicians*" and "*learned professors*" may be consulted and medicines furnished "without money and without price" *Armies* of people in this city who, if not thus enticed, could have maintained themselves, their self-reliance and self-respect, have taken their first step into mendicancy by the by-road of the *free dispensary*

"Who steals my purse steals trash, but he who filches from me my 'self-respect' robs me of that which not enriches him, but makes me poor indeed"

Any one who has given study to the subject of scientific charities understands the danger which lurks in the giving of "out-door relief" The danger is to the beneficiary, it tends to pauperize the dependent, and, doing so, the injustice is visited upon society and the State Thus the individual is robbed, society is damaged and the State is put to expense because of this pernicious, indiscriminate alms giving, and the *free dispensary* is the most perennial robber of them all! Watch the course of the candidate A morbid desire for gratuity robs the mind of thoughts of higher purpose The vial of dispensary tonic creates an appetite for free hams, free flour and free coal Attendance at the dispensary is certified to the town agent, who is importuned to supply all temporal needs, in this manner the malinger finds encouragement, the dependent is pauperized to the detriment and damage of us all, while the premium stands on indolence and disgrace

Can the robbery of the poor be made more complete than by changing to a pauper a person capable of self-support? Can anything be more baneful than to induce one to cease to depend upon the strong arm of self-reliance and become a recipient of gratuitous commodities

"There are more diseases than hysteria that people love to suffer with, and the dispensary-affection is an example There is no evil that is more ruinous than the awful one of communism When a man gets that poison in his blood he will be a curse to the world until he is well hanged, thoroughly dead and everlastingly buried There is no curse so fatal as the curse of desiring to get something for nothing It is the half-hidden rock upon which the very ship of state, democracy itself, is running headlong Nothing is serving so subtly and so powerfully to prevent physical and social health, and to keep the world in the thaldom of disease, as medical beggery and medical communism When a man buys medical service for nothing he pays a high price for it He cultivates the habit of lazy reliance on medical aid, and grows careless of hygiene The people think they are fortunate in being treated for nothing, but instead of curing, the "treatment" really fastens the disease perpetually upon the very heart of the body politic"[1]

I desire not to be understood that the dispensary is the only source of pauperism It is simply the topmost flower of a weed that is sapping the life blood from myriads of useful plants Shall we welcome a reform?

"There can be no doubt that the instant influence of the necessity of treating crowds of mingled deserving poor and indistinguishable spongers, acts disastrously upon the physician's disposition and manners The very work wherein gentle kindness is as the sunshine's benediction over the gracious harvest fields of benevolence is transformed into bitterness and harshness What is more disgusting than arrogance and dictatorialness in a physician? What is more common in hospitals and dispensaries? A dog judges of his master's mood by the manner and the *timbre* of voice, although he understands hardly a word of language proper Every hospital patient, likewise, forms quick conclusions as to the man's character under whose care he comes, and instead of gratitude for the service rendered the ungentlemanly physician is breeding through the community a condition of mind that bodes no good for medicine The patient thinks himself sharp to secure some benefit from grudging surliness, and the overworked, non paid, half-excusable doctor is glad to get through his job in one or another wretched way 'He has the European habit and style'—such is the patient's verdict The patients know well enough when they are looked upon as 'clinical material'"[2]

In the city of Philadelphia, in this respect the worst cursed city on the continent, the Bureau of Charities offered its assistance to see that impostors should be excluded from the dispensaries The physicians in charge declined, saying, "We want the impostor for his influence, we want the doors left wide open, let everybody come" In this we have an exhibition of the willingness of men, and must I say physicians, to compromise principle, to compromise the good of society and the State, not to say the profession to their own individual selfish aims I therefore appeal to you as citizens of this, the *greatest city* of the *greatest nation*, to use the intelligence of the physician to guide you in your duty as men to reform this evil which menaces society Not solely because it robs the doctor of paying patients, but because it robs the individual—the recipient—of his self reliance, of his self respect, places barriers between him and honor and turns his face toward the dust!

This side of the free dispensary evil, this pauperizing of dependents, this robbing the poor of their right and title to respectability, appeals to you, it appeals to every medical man in Chicago, and if we who are connected with the evil, and likewise those who are not, shall choose to lie supinely upon our backs and wait, we will find that the awakened intelligence of society will visit upon us the sad *necessity of becoming followers in a reform we should have* led The study of scientific charities is fast carrying the seed of truth where it will bear most fruit, and if we would regain the respect and social standing accorded our fathers we must awaken to the demands of the hour Stated plainly, the evils which require correction are as follows

---

[1] "Hospitalism," by A M Gould, M D Phil

[2] "Hospitalism," A M Gould, M D, Phil

1 Prevent the physician or surgeon, who does dispensary work from using his office as a '*cats-paw to rake the chestnuts from the fire*"

2 Prevent every one from receiving treatment at dispensaries except those actually too poor to provide for them selves

This will decrease attendance 50 per cent I say 50 per *cent* on authority[3] of all those who have made investigations I must question the reliability of the estimate made by Dr Davis This should also stop the use of dispensary patients as decoys for private waiting rooms and make dispensary work honorable

To this end it is necessary that there shall be selected a board of *censors* with *sense*, and who shall become *incensed* if abuses continued

THE DISPENSARY EVIL—INJUSTICE OF THE DISPENSARY

By E H DORLAND, M D, Surgeon to Lakeside Hospital, Chicago

Our subject defines itself It is not for us to discuss a doubtful proposition, but the *dispensary evil It is then* assumed, believed and recognized, that the free dispensary is an evil and that it requires no argument, no array of facts in this presence, to convince our hearers that the free dispensary is an evil It may be further assumed then that the scope of the discussion is to be confined to the exposition of the evil, and to the means to correct that evil While the profession is, in the main, responsible for this *dispensary* evil, the individuals, the organizations, churches or what *not, that furnish* the money to equip and maintain the free dispensary make a great mistake and do the *medical pro fession* a great injustice There are so many ways of *spending* money for the benefit of the whole community without wronging any part of it, that with slight exception, the man who endows a free dispensary does vastly more harm than good to the community, and directly wrongs the medical *profession* From a humanitarian standpoint one heavily endowed and well-equipped laboratory for the promotion of sanitary science would do more for Chicago than all the free dispensaries in the city The *motive* of the man of money, or the charity ball or the high toned *gambling scheme of the* church social, may be good but their efforts, and the result of their efforts are bad The well-meaning, but misguided minister who urges, even implores his church on 'Dispensary *Sunday*" to contribute a goodly sum for the free dispensary, *is enjoying* the delusion that he is working for a noble charity, and a side-factor is the dispensary doctor, who is working the church for advertising purposes and who is specially *active* and conspicuously officious on these occasions Many of us have observed a *man with a Solomon* Levi appearance, a prominent bidder at a church fair free dispensary push, pay $20 for a thing worth 20 cents An allusion to these "tricks of the trade" is sufficient, it will bring to mind the long and disgusting *list of* practices under the guise of charity that it is hoped that enlightened charity will banish from good society *in the near future* There are degrees of this evil, there are comparatives and superlatives *of this evil* There are two special divisions of the *injustice* of the free dispensary to medical men First, the direct injustice in that it takes a very considerable number of patients from their offices that could and would pay something for treatment, second, that *far greater* and more damaging injustice, that of prostituting a profession consisting of a body of learned men, men constituting preëminently the learned profession, to a standing below *that of* a trade, or even a day laborer, in that their services can be had for *nothing* The free dispensary educates people to expect something for nothing, than which *no* greater evil to a community can be done This phase of the subject should be *continuously* emphasized as the people can see and appreciate this side of the subject more readily *and clearly than* any other One of the most humiliating spectacles in the *whole round* of this dispensary evil, and one that does the medical profession the greatest wrong and injustice is that of the man who perpetrates the farce of diagnosing and prescribing for ten, twenty-five or fifty cases *in an hour* If it was for legitimate *teaching for the* boys on the benches, *two* cases properly handled, properly and correctly diagnosed and skillfully prescribed for, would serve the purpose infinitely better Another form is exhibited in the voluminous writings of the dispensary doctor The free dispensary literature, and reports of cases treated at free dispensaries, are wholly untrustworthy, and are wholly worthless *to the student of medicine I believe* I voice the consensus of opinion of the medical gentlemen of my acquaintance when I say that I believe that there has never been such a volume of stuff in the shape of reprints and clinical reports as at the present time flood the offices of the profession I believe further that I state a fact in saying that from 60 to 90 per cent of this "stuff" is not worth the paper it is printed on to the profession, and that the light of it is most observable when used as kindling with which to light the evening fire on the grate, by the warmth of which to read *books written after an exhaustive study of the* subject in hand, and in which scientific facts are stated and the doctor left to draw his own conclusions The obvious injustice to the profession exhibited in the rough, gruff, unseemly and boorish manners of the dispensary doctor is another great wrong and misrepresentation of the medical profession Practice in the dispensary unfits a man for practice among refined people *Of these* people that crowd into the free dispensary the doctor knows nothing, knows nothing of their habits, manner of living, thinking, speaking, working, *eating, drinking, or their* environment in any way The whole free dispensary tends to teach the people to *hold us in* contempt The spectacle of doing business *free* exists in no other walk of life, and it has always been true and is true to day, that the people do not appreciate that which costs them nothing The teaching factor in the free dispensary is as near worthless as anything can be It is a very rare thing *that a physician* who enjoys an experience in a refined private practice attends a free clinic If there is nothing there desirable for him to learn, can that instruction be of *any real* value to the medical students? If the dispensary doctor is there for his own instruction it would *seem that it* takes him a long time to "learn his trade," whatever he treats, whether it be eyes, or throats or wombs or feet

The impression is kept very prominently before the people that they will be examined and treated by the great professor at the free dispensary, and it seems that some of our medical men favor and prefer the title of ' Professor" to that of ' Doctor " This impression, this figure head of the "*Great* Professor" is, in the main, a gigantic fraud practiced upon the people As in politics, so in dispensary professorships, a man of money, or influence, or *ability holds the office, but* some one else does the work We can teach the people that the free dispensary is for paupers, that the service at a free dispensary is not at all like that of a private office, that the acting free dispensary doctor is not the best doctor, that he is a man of little or no experience and is there to experiment Let the dispensary *doctor, if he* is sincere do what he can, and he can do a great deal more than he does do, *to* weed out and kick out the dispensary parasites In this corn and *hog city of ours* we have a large class of people of very little refinement and less taste that will accept the free-dispensary service and is wholly unworthy of it in every particular The free-dispensary doctor will perscribe for this class of people and belittle and humiliate himself and disgrace the profession in doing so Charity is greatly exaggerated and overdone in Chicago but no charity is so terribly abused as the free dispensary A careful estimate will show that there is no legitimate need for more than one fourth *of the free dispensaries* that now exist, unless it is to advertise the doctor that is giving his life for the people It is often a most pathetic sight to observe the efforts *of* "Mrs" Free Dispensary Doctor, or her mother in-law, as solicitor of funds to maintain the free dispensary *It is* very apparent, too apparent in the main, that the free clinic is an advertising institution I venture the statement that the better you know the *free dispensary*, its professors and its methods, the less you will admire the free dispensary, its professors and its methods As ever, so now, bigotry is universally an evidence of ignorance Let us not deceive ourselves into the belief that unqualified statements and bold assertion are indications of erudition Let us withhold our approval and discontinue all patronage to the men that are willing to lend themselves to the perpetuation of this gigantic abuse and injustice There are plenty of better doctors than those that are mere teachers The profession is, to a degree, responsible for the bigotry, too prominently and painfully observable in the free-clinic professor The average free-dispensary promoter is just about the size mentally to be spoiled by the admiration and applause of first-year medical students We can do much to correct this abuse by raising the matriculation grade for all medical students Let a bachelor's degree be required to enter any medical college When this is done our young men will attend the full four or six years' course at the universities of medicine instead of stock company medical colleges University professors do not need to resort to any such methods The number of patients that are treated free has more than doubled per 1000 in the last ten years Are the people less able to pay for medical service than they were ten years ago? There is nothing within the confines of medical practice that has wrought such harm and injustice to the profession of medicine as the lesson the people have so readily and all too well learned —that they can get medical and surgical treatment for nothing

---

[3] Warner's American Charities chapter on 'The Destitute Sick Investigations in New York of several thousand dispensary habitues revealed that 25 per cent were found to be abundantly able to provide for themselves another 25 per cent had given the wrong address to conceal themselves This left 50 per cent who were rightfully entitled to participate and who were being robbed by the impostors

BOOK NOTICES

Medical and Surgical Report of the Children's Hospital, 1869-1894 Edited by T M Rotch, M D, and Herbert L Burrell, M D Boston Published by the Board of Managers 1895 8vo cl

This sumptuous volume with its elegant paper, beautiful illustrations and well-written text, tells the story of the founding, the development, and, we were about to say, the perfection of the hospital The contents of the volume are as follows

Division i—(*administrative*) 1 The History of the Hospital, by Francis H Brown, M D, who has been Secretary of the organization from the beginning in 1869 2 The Executive Management of the Hospital, by the lady Superintendent, Sister Caroline 3 The Convalescent Home 4 The Outdoor Relief Department

In Division ii (*medical*)—we have a series of interesting short essays 1 Typhoid Fever, by F Gordon Morrill, M D 2 Value of Milk Laboratories for Hospitals, by T M Rotch, M D 3 Relation of Aural Service to the Needs of a General Hospital for Children, by Clarence J Blake, M D 4 Malaria in Children, by E M Buckingham, M D 5 An Epidemic of Scarlet Fever, by Thos F Sherman, M D 6 Etiology of Chorea, by Chas W Townsend, M D 7 An Epidemic of Diphtheria Apparently Stopped by Use of Antitoxin, by F Gordon Morrill, M D

Division iii (*surgical*)—is divided in three parts, the first being a description of the work done in the surgical wards of the hospital, in the surgical out-patient department, and in the surgical appliance shop The second part gives a description of the standard routine of procedure in the classes of cases treated at the hospital This includes description of the arrangements for the operating room, sterilization and dressings, gymnasium, form of records and blanks, etc Third part contains a series of original papers by E H Bradford M D, R W Lovett, M D, Herbert L Burrell, M D, W N Bullard, M D, H W Cushing, M D, and E G Brackett, M D

Few hospital reports are of more practical value, and as an exponent of *fin de siecle* medicine and surgery its authors will take a front rank

A System of Surgery—By American authors Edited by Frederic S Dennis, M D, Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical College, New York, President of the American Surgical Association, etc, assisted by John S Billings M D, LL D, D C L, Deputy Surgeon General U S A To be completed in 4 im 8vo vols, 900 pp each, with index Profusely illustrated with figures in colors and black Vol iii, 908, pp, 207 engravings and 10 colored plates Price per vol, $6 cloth, $7 leather, $8 50 half Mococco, gilt back and top For sale by subscription Philadelphia Lea Brothers & Co

This volume has been continued on the same plane of excellence as its predecessors The plan of the work makes this volume include among its contributors the names of several well-known specialists outside the ranks of the surgeons The contributors to this volume include Drs D Bryson Delevan, Henry H Mudd, Charles B Porter, Willard Parker, Fredrick S Dennis, George E de Schweinitz, Henry D Noyes, John E Weeks, Gorham Bacon, Louis McLane Tiffany, William A Hardaway, J William White and Robert W Taylor

Dr White gives a great deal of space to the subject of castration in certain cases of prostatic hypertrophy, and Dr Dennis presents a conservative view of pulmonary surgery Dr Parker an excellent resumé of bronchial cysts, and Dr Taylor gives some very recent methods of bubo treatment, and we might easily say some very late views on the general subject of syphilis The volume as a whole is fairly representative of the existing state of the topics under consideration A book of this kind, as a rule, does not assume to promulgate original investigations, but only to record the science of the day as it is understood Whether the more ephemeral topics and methods shall be included largely depend on the judgment and tact of the editor In all such matters, Dr Dennis has so far displayed a taste and judgment creditable alike to his wise discretion and to his common sense We shall look with renewed interest for the appearance of the concluding volume

Diphtheria and Its Associates—By Lennox Browne, F R C S, editor Illustrated by the author London Baillière, Tindall & Cox Philadelphia J B Lippincott & Co 1895 8vo, cl

This monograph is one that will naturally attract much attention, not only on account of the deep interest attaching to the subject itself, but because of the high standing of the author There are thirteen chapters in the book, namely i History of Diphtheria ii, iii and iv Etiology v Pathology vi Bacteriologic Diagnosis of Diphtheria and its Associates vii Clinical Diagnosis of Diphtheria and its Associates viii Record of Illustrative Cases, etc ix Elements of Prognosis in Diphtheria x Treatment of Diphtheria and its Associates xi Laryngo tracheal Diphtheria Croup xii Hygiene and Prophylaxis xiii Formulæ for Remedies in Diphtheria

There is an appendix in which the serum treatment of diphtheria is discussed in all its bearings This section is an exhaustive summary of the existing knowledge of the subject The accidents of the serum treatment are not extenuated, but on the contrary, as will be seen by reference to another column, its use is distinctly condemned But leaving aside the question of serum-therapy, the book will stand as an able and authoritative exposition of the subject of diphtheria

Electro-Therapeutical Practice—A ready reference guide for physicians in the use of electricity By Chas S Neiswanger, Ph G Flexible covers, pp 30 Chicago 1895

This book is said in its preface to teach "plain facts and simple rules" for practitioners The method adopted by the author is, to say the least, peculiar The common list of diseases is presented, and under each name the manner of applying electrical treatment There is no half-way or faint-hearted system recommended in this book, for this pharmacy graduate has no pathologic or diagnostic doubts, but like the "plain, blunt man" that he is, he goes right on to apply electricity without let or hindrance to all kinds of diseases and conditions, from an abortion to a case of exophthalmic goitre There are some good points of technique, but as a whole the book belongs to a class that had better not have been written

Outline of Materia Medica and Pharmacology—A text-book for students By H M Bracken, M D Philadelphia P Blakiston, Son & Co 1895 8vo, cl Price, $2 75

The author informs us that it is intended the book "shall serve the purpose of a text-book, for use in the study of materia medica, to facilitate note taking in the lecture room, and to aid in the laboratory study of drugs" The metric system has been given the preference throughout The book has been carefully compiled, and in our judgment is destined to become a very popular text book Although particularly intended for students, the practitioner will find it instructive, especially with respect to the newer remedies, and as a convenient work of reference

SERUM-THERAPY IN DIPHTHERIA

Just as we were growing comfortably settled in the conviction that if there was anything in the doctrine of serum therapy, it was surely in cases of diphtheria that its strongest statistics were to be found, along comes one of the ablest Laryngologists of Great Britain, MR LENNOX BROWNE, and in an able discussion of the subject,[1] reviews the question adversely After stating as a result of his experience that with serum-therapy "a greater number of children have been found liable to attacks of cyanosis and fainting, with a correspondingly increased demand for nervines and stimulants," and that "complete recovery is for the most part found to be greatly delayed, and an unexpected fatal result at a late period is more frequent," he continues "When drawing attention at a meeting of the Clinical Society last December to an increased liability to the most grave complications of diphtheria, viz , anuria, nephritis and cardiac failure under the use of serum, we took occasion to express a hope that further experience might prove that the disadvantages of serum would be more than outweighed by its benefits "

Having carefully compared the results of 1,000 cases in which there were 284 deaths, and divided them into hundreds, he states that "the actual mortality was the same, namely, 27 It was 27 10 on the whole number—1163—treated during the year 1894 at the hospital whence our comparisons were made"

After a lengthy weighing of the result of his observations he thus concludes

"The foregoing observations as to the effects of serum treatment will, we trust, have made it clear that the injection of antitoxic serum into a patient attacked by diphtheria is not altogether free from an added danger, notwithstanding that the amount of active principle administered can be measured only by millionths, and we have seen that the power of this serum to do good and *per contra* its capacity for inflicting injury is in proportion to the duration of the disease—in other words, to the degree of the toxæmia

"As a corollary, we might be able to pronounce that the power of antitoxic serum to act as a prophylactic against a possible attack of diphtheria is in proportion to the rigor and healthy blood condition of the individual in whom it is employed, but the very minute dose administered for this purpose is evidently capable of being soon broken up by cellular action in the healthy

"We can, therefore, understand the general admission as to the evanescent character of the immunity so obtained Moreover, reports of cases are not wanting in which noxious and even fatal results have followed the use of serum when employed as a prophylactic

"On all these grounds, therefore, we do not feel justified in recommending serum for this purpose More real methods of preventing the spread of diphtheria are to be found in improved sanitation, in prophylactic surgical treatment already detailed, and in efficient isolation and disinfection "

It is pointed out that in many of the continental hospitals where the results of serum-therapy are asserted to show such remarkable diminution of mortality, that the former mortality statistics in the same hospitals were greatly in excess of those obtained by strict adherences to the classical treatment so ably carried out in some of the British hospitals

The JOURNAL in thus giving its readers the conclusions of one of the ablest specialists of London, wishes once more to emphasize the necessity of making haste slowly in accepting every continental fad that is forced upon us Let the memory of the BERGERON treatment, and of the tuberculin be a sufficient warning, without making ourselves ridiculous by undue haste There are so many opportunities for having new theories tested on a large scale in the world's great hospitals, that the general practitioner may well exercise patience while the great problem is being worked out In the matter of diphtheria let us remember that wherever the disease is *immediately treated* by appropriate local remedies, recovery is the rule Frequent inspection of the children's throats, and thorough cleansing of the nasal passages, will prevent the disease in many cases Prevention is not only better than cure, but the dangers of hitherto unknown horse toxines, may be avoided

Larger and more extended experiments, which we would by no means discountenance, may indeed demonstrate the truth of the claims brought forth by those anxious to herald a new discovery, but in the meantime the general practitioner can afford to adopt more stringent precautionary measures, more active local methods, and WAIT!

---

THE NEEDS OF THE MEDICAL DEPARTMENT OF THE NAVY

The annual showing of the Surgeon-General of the Navy exhibits the medical corps of that service at a still lower level in its *personnel* than a year ago One by one, its men of experience are lopped off from the top by the statutory limitation of age, though in the full vigor of mind and body, while a rare addition to its foot at long intervals, of an occasional recruit fails to arrest its steady ebb Fourteen vacancies in a corps which only consists of 170 members, when its ranks are filled, at a time when employment is eagerly sought by young men in every vocation, are significant of something wrong in a body which was once recognized as the *corps d' élite* of the Naval Service

The examinations for admission are no more severe than formerly, and are probably not so exacting as in the days of the old Philadelphia Board, when it was considered high honor to pass its ordeal and when men were examined in anticipation of vacancies, which sometimes did not occur within the year, compelling the successful candidate, for whom there was no place, to submit again to a trial a year later Then faculties urged the brightest of their graduates to go before the Naval Medical Board, and rival colleges took pride in the number of their men who passed To-day there is not a school or teacher in the whole land that does not dissuade their young men from entering the Naval Service The reason is plain enough—the unsatisfactory position of the medical officer of the Navy, and the relative inferiority of his status and pay to those of his professional brethren in the Army The profession properly resents the degradation of the bearers of its diplomas to the level of school boys from the Naval Academy, and the studied contumacious treatment to which they are subjected throughout their whole career by the tyrants of the quarter-deck

The leading national medical organizations have appointed committees during the past year to urge upon the next Congress, now about to convene, remedial legislation looking to the elevation of the status, pay and emoluments of the Naval medical officer to those of the medical officer of the Army, though the Army itself has cause for complaint in the matter of its insufficient numbers, but its medical officers are officers in fact, as well as in name, and they are recognized and treated as such, without any of the wretched evasions and discriminations which prevail in the Navy An Army medical officer *commands* his hospital, a naval medical officer is only "in charge" of a naval hospital, though in it there may be two or three hundred officers, employes

MODIFICATION OF THE "RED CROSS OF GENEVA" AS THE PROPOSED SYMBOL OF MEDICINE

Some of our friends find time to work out the symbolism and esthetics of their profession When they do this cunningly and tastefully they well merit our thanks Accordingly, the editor of the *Boston Medical and Surgical Journal*, in his issue for Nov 14, has our gratitude since he appears to have hit upon a proposition that may meet with a very general approval His advice, in brief, is that the Geneva Cross, somewhat modified, be adopted as the emblem of medicine, whether in art, literature or organized undertakings

It appears that the question of proper insignia has been under consideration by officers of the medical department of the Army When their conclusion shall have been reached such selected insignia will probably also be accepted by the militia of the different States Possibly the medical department of the Navy will adopt the cross, with a suitable distinctive modification

The editor of that journal says "Recently published remarks concerning a distinguishing device for the medical department of the Army bring to mind the whole subject of medical symbolism, in both its civil and military application After extended research among the histories and other records of ancient and modern times, together with observation of customs yet extant among socio religious communities, a form has been found which appears to answer the requirements necessary to appropriate insignia by which to characterize medicine It is well known, to those informed in such matters, that the caduceous—the emblematic staff and serpents—also serpents in different postures and variously associated with other objects, and the cross in its many forms and combinations, are outgrowths of one and the same root Numerous other things, more or less used as symbols of medicine, such as the oak, palm, gallus, *et alia*, have the same origin Moreover, the Geneva Cross, of the Red Cross Society, is now recognized the world over in its best practical application

"We have here, therefore, a proper symbol of the healing art, fitting in its origin, significance and actual use by civilized humanity The ordinary design might be improved upon by lengthening, very slightly, the arms of the cross, so that the square forming the center would be a trifle smaller than the corresponding part of the actual Geneva Cross This variation is recommended for the reason that in the common form of the red cross, the great mass of color in and about the center causes an apparent lack of proportion, by making the middle square look larger than it really is This optical illusion would be corrected by this suggested modification For use on military uniforms the cross might be of some handsome shade of red, made of durable material set in gold If the red cross is used as a medical emblem, it should be recognized that it is of international significance, and a red cross with gold about the edges is ornate and might serve for a collar device to designate a medical officer "

The red cross is an emblem of neutrality, and should be easily distinguishable at a distance, and thus protect those who by the treaty of Geneva are classed as non-combatants, though it is probable that, with the present long range firearms, non combatants, whether medical officers or newspaper correspondents, will have to take the common chances There is one other suggestion that may be made in the carrying out of the hints given in the foregoing paragraphs, namely, the central square made by the four outlying arms may be left uncovered, so as to receive a lettering or emblem suitable to the respective subdivision of the army, navy or militia This central square may be graded by the use of gold, silver or other materials, for higher and lower ranks, or other distinctive markings or colors may be developed according to the variant occasions for differentiation

THE EVILS OF A LIMITED TENURE OF OFFICE OF HEALTH OFFICER

By reason of a strong paper before the recent meeting of the British Medical Association, read by Dr Whitelegge, on the above subject, a concerted movement is being made in England to secure a fixity of tenure of Medical Officers of Health in a greater degree than already exists A far larger proportion of English sanitary officers has permanency of tenure than is the case in this country, but altogether too large a number feel the pinch of uncertainty and its accompanying handicaps The editor of the *Sanitary Record* comes trenchantly to the front on behalf of these slighted officials, whose very livelihood may be in jeopardy from the caprice or parsimony of the respective local boards of more or less ignorant and politically-inclined laymen Politics and health administration mix with as little facility as do oil and water—when they do mix, to any good purpose, it is by dint of prolonged *agitation* The agitation in this particular instance has been begun, and will without doubt be continued to the end In this country, no such beginning has been made and can scarcely be hoped for until we have, at least, as a starting-point for the building up of a consistent and uniform code of sanitary regulations, a NATIONAL DEPARTMENT OF HEALTH

The remarks of the editor of the *Sanitary Record* on fixity of tenure for medical men in sanitary life are, in part, as follows

That it is in the highest degree desirable that competent officers should be so far independent as to be able to act in the way they deem best for the public good without the fear of dismissal or of reduction of salary, should they, in the performance of their plain duty, give offense to a member of the Board, or to some person of local influence, no one can seriously doubt, but the question is by no means so simple as that of securing the like protection for the Sanitary Inspectors, for the duties of these latter officials, and the areas over which they exercise them, are not likely to undergo any very great change. But the medical branch of the sanitary service is at present in a state of chaos, presenting a serious obstacle to progress, which it would be folly to perpetuate. Though some few Medical Officers of Health have succeeded in combining the efficient performance of their official duties with private medical practice, their cases or their circumstances have been exceptional. The ordinary practitioner finds himself hampered at every step; his attention is divided, his time is not his own; the calls and interruptions of practice render continuous investigations wellnigh impossible, and every difficulty felt by the Medical Officers of Health at the mercy of a Board is felt a hundredfold more painfully by a man who can not afford to give umbrage to his patients, to say nothing of possible friction with other medical practitioners. Twenty years ago such appointments were a practical necessity, but it was, doubtless, in view of their gradual supersession in the not distant future by others of experts to larger areas, that these were made in the first instance for periods not to exceed five years. Some of these men have developed into experts, a new generation of specialists has arisen, and a number of whole-time appointments and of combined districts have been created without our being much nearer the realization of the ideal, since the appointments originally intended to be provisional are repeated on all sides, and those fulfilling the conditions required for permanency are still made temporary.

The question is one that only a strong Government can take in hand, but the present time seems most opportune. No doubt the army of small officers who add various sums from £5 to £100 to their incomes by accepting or assuming functions for which they have no special aptitude, just as they would take the more congenial work of a club or a poor-law appointment, will resist the change, but it must not be longer delayed, and for any medical officers who really have their hearts in the work, plenty of room could be found in the new combinations.

OVERDONE STERILIZATION

There is a golden mean in all things and even the most salutary and sanitary practices can be carried to excess. In what may be termed microbophobia, the extremes of caution as to the exposure to pathologic germs, there may be a danger on the other side; one may, in avoiding the Scylla of organic infection fall into the Charybdis of chemical poisoning, or starvation. These thoughts are suggested by a paper by DR. LOUIS STARR in the December number of the *American Journal of the Medical Sciences*, in which he gives details of three cases of infantile scurvy due to the exclusive use of sterilized milk; and he further states that he has seen five other cases in consultation within eighteen months. He attributes the disease to the alterations that occur in the milk during the process of sterilization, especially in the lactalbumin which has its solubility diminished, and in the fat globules which coalesce with each other and with some of the insoluble albuminous matters. All the cases recovered promptly on a diet of unsterilized milk together with raw beef juice and orange juice and tonics.

DR. STARR seems to have no doubt as to the chemic nature of the toxic agent, but the suggestion is not a very unnatural one that there may be even some organisms in the diet that are beneficial if not essential to its wholesomeness. It is, it is true, generally held that the enzymes or unorganized ferments play the chief part in human digestion, but the final word has not yet been spoken on the question and there may still be a possibility of a certain utility of the lower organisms in digestion in man as there is undoubtedly in the herbivora, or the microbes, while not acting directly in digestion may, by their presence and products, indirectly aid the chemical changes in the process. While admitting the probability of the chemical alterations caused by the sterilization process being sufficient to account for the phenomena of innutrition and scurvy that were observed, it may be as well also to not altogether lose sight of other possibilities.

In our warfare against pathogenic germs it is well to remember that, as a rule, they require a suitable soil for their development, a point of least resistance for their attacks, and that most of them are comparatively harmless where this is lacking. We send consumptives to swarm together in Colorado and California, and to their advantage, notwithstanding the concentration of infection we thus produce; and likewise, whenever we lower the systemic tone by seriously modifying natural processes and conditions we open the way not only to outer infection, but perhaps still more to the dangers of auto-intoxication from the toxins produced in the system which require its normal condition for their safe disposal.

There is an extreme in this matter, that, baldly stated, would seem to any one ridiculous, such as the carbolated kiss; but there are more common practices less radical than this that fall somewhat short of the sweet reasonableness that should govern the conduct of a scientific physician, and, as we have seen, even apparently rational procedures sometimes fail of being fully on the safe side.

It is not intended here to say anything against reasonable precautions, but simply to *call attention* to a possible danger from lack of a comprehensive view of all the possibilities in any particular case.

SALE OF MEDICINES IN ORIGINAL PACKAGES

The "original package" and 'interstate commerce" contention has now, after a season with almost everything else ranging from liquors to pianos, been attached to the sale of medicines. Iowa has a statute which requires, under penalty, that any itinerant vendor of any drug, nostrum, ointment or appliance of any kind intended for the treatment of disease or injury, who shall by writing or printing or by any other method publicly profess to cure or treat diseases or deformity by any drug, nostrum, manipulation or other expedient, shall pay a license of one hundred dollars per annum, to be paid to the treasurer of the commission of pharmacy This statute, it was argued in the case of State v Wheelock, decided by the Supreme Court of Iowa, Oct 10, 1895, is repugnant to the clause in the federal constitution which provides that Congress shall have power to regulate commerce among the several States The defendant here was an itinerant vendor of drugs and nostrums, without a license, within the meaning of the State statute, while the medicines he sold were in the original packages in which they were shipped into the State Thus was fairly presented this important question

To begin with, the courts admits that the power vested in Congress to regulate commerce among the several States is a power complete in itself to prescribe the rules by which that commerce is to be governed, that it is coextensive with the subject on which it acts, and can not be stopped at the external boundary of a State, but enters it, and is capable of authorizing a disposition of articles of commerce so that they become a part of the common mass of the property within the State But, citing several decisions of the Supreme Court of the United States, it says that it has been held that State laws which do not discriminate between residents and products of a State and those of another State, which are not designed to interfere in any manner with interstate commerce, as those, for example, which are in the nature of a simple tax upon sales of merchandise, imposed alike upon all persons, whether residents or non-residents of the State, are not repugnant to the constitutional provision in question However, after pointing out that there is no discrimination in the statute under consideration, the court goes on to state that its primary object is not to derive a revenue for the use of the State, but in large part, at least, to protect its citizens against solicitations and harmful practices of irresponsible and unknown traveling vendors of drugs and other articles intended for the treatment of diseases or injury, who, in carrying on their business, publicly profess to cure or treat diseases, injuries, or deformities and thus promote the sale of their wares to the credulous Indeed, the act here prohibited might be committed without any actual sale

The conclusion of the court is that the enactment in question is within the police power of the State Narrowing the discussion, it says that the right to sell, in original packages, medicines brought from another State, does not include the right to have sold by an unlicensed itinerant, who, to make sales, professes knowledge of the art of healing Statutes which apply to such sales are not, in any sense, regulations of interstate commerce, but a reasonable exercise of the police power of the State, which may be applied as well to articles of interstate commerce in the hands of the vendor, and offered for sale in the original packages, as to articles produced within the State

The amount of the license fee required by the statute, the court declares not to be excessive, and the regulations thereof, it pronounces reasonable

THE DEPARTMENT OF PUBLIC HEALTH

As announced in our Washington column last week, the Chairman of the Committee on the Department and Secretary of Public Health, Dr Jerome Cochran, has appointed an auxiliary committee in Washington, consisting of Drs H L E Johnson, S C Busey, C H A Kleinschmidt and J R Wellington The Association bill has not been introduced this session, but the old Bureau bill has been introduced in the House The Association does not ask for a Bureau, it wants a Department, and intends to be satisfied with nothing less

CORRESPONDENCE

The Atlanta Meeting

Rockford, Ill, Dec 6, 1895

To the Editor —Permit me to suggest that the Transportation Committee of the Association soon begin considering and agitating the question of railway rates to the meeting at Atlanta next May It is not sufficient that transportation be secured for the editors of medical journals who have secured a square or half page of advertising from railways and connecting lines to Atlanta These journals may "whoop up" the meeting, but the rank and file, the bone and sinew of the profession, will not get there unless some generous concessions are made by the transportation companies

Would it not be a good plan to secure a pledge in advance from the city or cities bidding for the Association to guarantee a cheap railway rate? The G A R the political and the secret society conventions do this, or begin work early to secure minimum rates The National Teachers' Association has just secured a rate of one cent per mile to Buffalo The Knights of Pythias are contesting for the same, and the G A R had this guaranteed in advance for the last three years There is no reason why the American Medical Association should receive *less* consideration from these corporations than other organizations I was going to say kindred organizations, but there is no Association that is akin to ours in any sense as far as regards great good to the common community of humanity, certainly the very antithesis of railway corporations in humanity's arena

The Journal has now secured a place and has a strength in affairs in the profession and out of it that will command attention It outranks all other medical journals and securing a large attendance at the meetings will secure a large subscription, and members will soon learn that the Journal fills all the requirements of the general practitioner, and that he can dispense with the subscription price of three or four for which he has been paying and apply the same toward liquidating the expense of his trip the Association meetings where he may, after a few successive attendances, acquire confidence enough to rise and express his views, not leaving the entire field of discussion to self-assured specialists or practical politicians and parliamentarians D L

Women Medical Missionaries

Boston, Mass, Nov 30, 1895

To the Editor —We are desirous of finding a fully qualified medical lady to go to Ceylon as a missionary of the American Board of Commissioners for Foreign Missions at as early a date as possible (not later than Oct, 1896), to open the work of the Woman's Medical Mission in North Ceylon The new buildings are in process of erection and will be completed according to the contract, furnished throughout and ready for occupancy within a few months The Medical Mission House for the residence of the lady doctors, is large and commodious The hospital will accommodate about forty patients The Nurses' Training Home will accommodate sixteen nurses and a matron Dr Louisa H Grieve (who is acting as a temporary supply until two permanent lady doctors can be secured for this work) has, at the branch dispensary, two days in each week, from fifty to one hundred patients each dispensary day The branch dispensary will be continued and the new dispensary, which is ten miles distant, will probably receive as many patients The American Board of Commissioners for Foreign Missions, the oldest and one of the most responsible Missionary Societies in the United States, which, on our recommendation, will appoint the lady doctors and have the general supervision of their work, will provide for the two medical ladies the usual allowances toward outfit, passage and salary, and will provide sufficient funds for the support of a staff of native helpers and for the current expenses of this Medical Mission for Women

Location The northern province in Ceylon, in which the Woman's Medical Mission is located, has a population of 300,000 people, all of whom speak the Tamil language All the women and children would be accessible to the lady doctors

Missionary Work Ten missionary families, connected with three societies, are carrying on missionary work There are about 3,000 native Christians who are communicants, and about 15,000 children under instruction in mission schools

Medical Mission Work Rev Dr and Mrs Dr Scott, both fully qualified doctors and missionaries of the A B C F M, have the oversight of the Medical Mission for men, which is located about a mile distant from the W M M Last year they treated over 4,000 patients, and they are now enlarging their hospital accommodation They have expressed their willingness to act as consulting physicians to the W M M

Funds The value of the land, buildings, furniture, equipment, medicines, instruments, and cash in hand of the W M M is over $20,000, and the annual income is estimated at about $3,000

Climate The climate is an even one, the thermometer ranges from 78 degrees to 93 degrees in the shade The rainfall averages about forty inches in a year The dry heat is less enervating than the moist heat of many other places in Ceylon and India Missionaries have lived and labored, in not a few instances, for thirty, forty, and in some cases even fifty years in this Province

If any fully qualified medical ladies who are readers of your journal, and who have work in the foreign field in view, would write to us, we would gladly give them any further information they might desire regarding this work

Yours truly,

Mary and Margaret W Leith

The Oldest but Latest Fad—Hypnotism

To the Editor —You will agree with me that it is a difficult matter to make *one cause* explain all phenomena Sometime in the past I wrote an article for the Journal under the heading, "Modern Insanity" and in a jocular way put it as a cause of many unique acts At that time I had not "read up" on "Hypnotism" Since reading the last number of the Journal I have reason to modify some of my views Hypnotism in its latest phase assists wonderfully in explaining a phenomena heretofore not understood For instance *One* who is a *multiple personality* can say in regard to his unusual acts, that Number 2 or Number 3, did the act, and therefore Number *one* is excusable Whether or not he could make a court or jury believe him is another question The average juror looks upon himself as a *unit* and may be hard to convince that any other individual is *more* Evidently the "Fool Killer" is dead or has ceased work How a medical man can be led astray by such idiotic "fads" as spiritualism, hypnotism, clairvoyance and other superstitions is hard to understand, and how a man can believe in hypnotism and yet not believe in "faith cures" is still another mystery The idea that a man can influence another hundreds of miles away without any means of communication is not mysterious but simply untrue The believers in hypnotism all agree that a man can not be hypnotized who is not willing Does this not prove that hypnotism is not a *remedy?* Can a man by will power alone resist the influence of remedies? Can he keep calomel from purging or ipecac from vomiting by will power? Does it not "make you tired" to think that leading men in the profession will not only listen to this preposterous "fad" but will write it up, and indorse it in the leading medical journal in the United States? I am a little surprised that the editor allowed the "fad" space When a man loses his identity and becomes two or three or a dozen different men then it is time to quit When I am in a happier mood I may say more along this line, but for the present am done Very respectfully submitted,

W P Howle, M D

Oran, Scott Co Mo

The Sun Glass as a Cautery

Washington, D C, Dec 10, 1895

To the Editor —I notice in the last issue of the Journal, a reference to the use of the sun glass as an actual cautery Permit me to call attention to the fact that this is one of the oldest cauteries Pliny, writing in the first century, Book xxxvii, chap 10, (Bohn's edition), says

"I find it stated by medical men that the very best cautery for the human body is a ball of crystal acted on by the rays of the sun"

It is unfortunate that Pliny forbore to give his authority for I can find no other reference to this method of cautery in the ancient writings that I have consulted Perhaps some of the learned readers of the Journal may inform us

Truly yours, An Old Member

Sulfonal in the Vomiting of Pregnancy

Allison, Iowa,

To the Editor —I have found this medicine a sure relief for this most obstinate trouble I have been using it over a year, have recommended it to neighboring physicians and never knew it to fail Those who have tried it say it works like magic It will relieve hiccough as effectually as well My method of giving is 10 to 15 grains (60 to 1) dissolved in two tablespoonfuls boiling water, and given as hot as the patient can bear it Sulfonal will stop vomiting of most any character, the quickest, safest and surest of any remedy n the category of medicine I believe every physician hould know this and hope the Journal will pass it around

S E Burroughs

PUBLIC HEALTH

Hygienic Examination of Water —At the twentieth meeting of the Society for the Care of the Public Health, at Stuttgart, in September, Flügge's opinions were embodied in the following conclusions 1 The usual hygienic consideration of water, based solely on the clinical, bacteriologic and microscopic examination *of submitted samples are in almost* all cases worthless 2 A single examination of a water must consist first of an inspection and an expert investigation of the source and nature of the surroundings In many cases this alone will decide as to its safety for use Usually a rough, physical examination and a determination of the iron and the hardness are a desirable addition Seldom is a further clinical, bacteriologic or microscopic examination necessary to make the decision sure In case of a new supply of ground water the freedom from germs must be especially assured 3 For the continued control of water supplies, the bacteriologic and sometimes the clinical analysis is advantageous The hygienic importance of noteworthy results of analysis is generally to be gathered only from the repeated inspection and examination of the sources of supply —*Deutsche Medicinische Wochenschrift*, Oct 31, 1895

The House We Live In.—This is the advice of the late lamented Prof J M Coates "Think deliberately of the house you live in, your body, make up your mind firmly not to abuse it, eat nothing that will hurt it, wear nothing that distorts or pains it, do not overload it with victuals or drink or work, give yourself regular and abundant sleep, keep your body warmly clad At the first signal of danger from the thousand enemies that surround you, defend yourself Do not take cold, guard yourself against it, if you feel the first symptoms, give yourself heroic treatment, get into a fine glow of heat by exercise, take a vigorous walk or run, then guard against a sudden attack of perspiration This is the only body you will ever have in this world A large share of the pleasure and pain of life will come through the use you make of it Study deeply and diligently the structure of it, the laws that should govern it, and the pains and penalties that will surely follow a violation of every law of life or health"—*Indian Med Rec*

Boiled Water a Preventive of Autumnal Fevers —The *Bulletin* of the Tennessee State Board of Health, for November 20th, contains a discussion of the prevention of the fevers that follow a hot and dry summer in the southern belt of States From the first settlement of Tennessee and the surrounding States it has been noted that a long, hot, dry summer or autumn was the sure precursor of the unusual prevalence and virulence of malarial fever This axiom has never failed in its forecast It is equally true now as it was in the early quarter of the *present century* Those who have been wise, even from earlier days, have found their *advantage* in the boiling of their drinking water Moreover, it is *now* known that the great prevalence of the fevers of the fall is not dependent wholly upon the climate, high temperature and decaying vegetation, but more upon the condition of the water supply in the regions affected *To quote* the pen-picture as sketched in the *Bulletin* "The long continued drought converts beautiful creeks into rocky beds, with loops of *stagnant pools* The springs often go dry The wells are almost empty Thus the water becomes foul from seepage, and no longer fit for drinking" It is *important*, therefore, to press home the simple preventive measure of water boiling upon the attention of the millions inhabiting the richest fields of the South and *Southwest* This vast region has been captiously condemned by many writers because of the *autumnal fevers* '*It* has been pronounced a malarial cursed region always doomed to mental *inferiority thereby* In all districts above described, the practice should be universal of *boiling all water* intended for drinking also this water should be cooled in covered vessels, thus avoiding contamination by any impurities in the atmosphere" The closing paragraph of the *Bulletin* is, in effect, as follows "If this simple and cheap means of changing very unhealthy water into innocent drink were universally adopted in all the malarious districts throughout Tennessee, the country would be as free from malarial affections as are the cities In our cities the few cases of autumnal fever that occur, especially if they be called typhoid, attract much attention and alarm In the country they are hardly noticed, because of their common occurrence At present, it may be safely affirmed that a hundred thousand Tennesseans, or neighbors, living within a city, are in better health than the same number dispersed through the hills and valleys of two or three beautiful counties In the city sanitation has become a main object with the people In the country they are still asleep" *Boil the water*

Health Reports —The following health reports have been received by the Supervising Surgeon General, Marine-Hospital Service

SMALLPOX—UNITED STATES

Arizona Nogales, Dec 1, 1 case
Michigan Detroit, Rochester and Park townships, Nov 23 to 30, smallpox reported
Louisiana New Orleans, Nov 23 to 30, 11 cases, 1 death

SMALLPOX—FOREIGN

Nogales, Mexico Dec 1, 1 case
Madrid Nov 12 to 19 9 deaths
Montevideo Oct 26 to Nov 2 8 cases, 1 death
Odessa Nov 9 to 16, 7 cases 1 death
Rio de Janeiro Oct 19 to Nov 2, 130 deaths
Rome Nov 14 to 21, 1 death
Rotterdam Nov 18 to 23, 4 cases
Warsaw, Oct, 26 to Nov 16, 2 deaths

CHOLERA—FOREIGN

Bombay Oct 29 to Nov 5, 6 deaths
Calcutta Oct 19 to 26, 86 deaths
Ceara Oct 24 to 31, 2 cases, 2 deaths
Osaka and Hiogo Oct 26 to Nov 2, 1 death
Yokohama Oct 25 to Nov 1, 4 cases, 4 deaths

YELLOW FEVER—FOREIGN

Cienfuegos Nov 24 to Dec 1, 4 deaths
Rio de Janiero Oct 19 to Nov 2, 18 deaths
Vera Cruz Nov 21 to 28, 1 death

RIO DE JANEIRO, Nov 5 1895

Supervising Surgeon General WALTER WYMAN, SIR I have the honor to remit report for the week ended Nov 2, 1895

There were ten deaths from accesso pernicioso, an increase of 2 9 from yellow fever an increase of 5, 54 from smallpox, a decrease of 26, 2 from Beriberi, a decrease of 2, 8 from enteric fever, the same as in the foregoing week, 45 from tuberculosis, a decrease of 10, and none from measles or whooping-cough From all causes there were 338 deaths, a decrease of 65

Yellow Fever—With the late increase in the temperature, there are appearing more cases of this disease, though, as yet, there is nothing to cause alarm, there appears to be a general uneasiness on this subject

Smallpox—In this week there is a great decrease both in deaths and cases of this disease, though it is still rife enough, and in the last three days it is still declining, what was to be expected with the hot weather In Victoria it still persists though it is further toward the equator, to the south and in the interior towns it is declining according to telegraph reports Respectfully yours,

R CLEARY, M D,
Sanitary Inspector, M H S

NECROLOGY

EPHRAIM W BULL, M D, of Concord, N H, died Sept 27 in the ninetieth year of his age He was a benefactor of his fellow countrymen in the discovery of the Concord grapevine and some others not so well known A writer in the *Independent* writes of his career as follows "Dr Bull was a native of Boston and physician there until ill health compelled him to give up his practice, in 1862, and remove to Concord, where he bought a small place about a mile from the station He was a lover of flowers and fruit and a close observer of nature The stories differ as to how he discovered the parent of the Concord vine The common one has been that Dr Bull noticed a wild vine of the *Vitis Labrusca* species growing on a fence, the fruit of which seemed a great favorite with the birds The skin of the berries was thin and tender and the flesh sweet and pulpy He removed it to his garden where it still remains, and grew thousands of seedlings from it, one of which became the Concord A visitor to the place has stated that Dr Bull told him he found the original vine on the place, removed there by a former owner Another account says that the Concord itself was the vine found growing along a woodland path However, the fact remains that it was Dr Bull who long and patiently experimented to improve and make the best of the native vine"

J Edwin Michael, M D, dean of the University of Maryland, died at his home in Baltimore Dec 2, of Bright's disease Dr Michael was born in Hartford county, Md, May 13, 1843 His parents were extensive land owners After receiving his early education in the schools of the county and being prepared for college by a private tutor, he entered Princeton, graduating in the class of 1871 He then came to Baltimore and entered the medical department of the Maryland University, from which he graduated in 1873 He was not known as a brilliant student at first, failing twice in anatomy, the branch he afterward made his specialty After leaving the University he traveled through Europe, taking courses in medicine in Vienna and Wurzburg On his return to this country Dr Michael settled in Baltimore, where he built up a large practice In 1876 he was elected demonstrator of anatomy in the University of Maryland and professor of anatomy and clinical surgery in 1880 In 1890 he was elected to the chair of obstetrics, immediately following his election to the deanship of the University He was a member of the American Surgical Association and ex president of the Clinical Society of Maryland At the time of his death Dr Michael was president of the Medical and Chirurgical Society of the State

David M Miller, M D, of Elizabeth, N J, who died at his home Dec 3, was prominent as a surgeon in Union and adjacent counties of his native State He was born in 1858 in Jersey City, and educated in arts at Princeton College, and obtained his medical degree from the College of Physicians and Surgeons, New York, in the class of 1883, and soon after settled permanently in Elizabeth

Prof Voitov —The death is reported from the Crimea of M Voitov, Professor of Bacteriology in Moscow, who has fallen a victim to his favorite science

Luther Pattee, M D, of Manchester, N H, died Nov 27 He was born in Warner, N H, Dec 1, 1831, and was the son of Asa Pattee of that place After a thorough preparation under the direction of various medical men he entered the medical school at Woodstock, Vt, from whence he was graduated in 1853 After practicing medicine in Canada for several years he removed to Manchester, where he remained until 1870, at which time he went to Boston After practicing in that city nearly five years he returned to Manchester, where he has since resided

A J Saylor, M D, of Frankfort, Ind, Dec 1, aged 45 —— John A Jones, M D, of Mansfield, Ohio, Dec 3, aged 64 He leaves an estate valued at $200,000 ——A J Hobart, M D, of Columbus, Iowa, Dec 6, aged 67 ——H K Palmer, M D, of Pueblo, Colo, Dec 7, aged 65 He was a brother of Senator Palmer, of Illinois

SELECTIONS

Physicians in the French Ministry —The new French Ministry includes three representatives of the medical profession M Berthelot, the Minister for Foreign Affairs, is a member of the Institute and of the Academy of Medicine, he took the M D, degree in 1865 M Viger, the Minister of Agriculture, and M Combes, Minister of Public Instruction, are also Doctors of Medicine MM Berthelot and Viger have each already formed part of several ministries M Combes, who now for the first time holds a portfolio is Vice-President of the Senate, in which he sits for the Charente Inférieure —*British Medical Journal*

Military War Trains —The Canadian Pacific Railway, after many months of labor, has constructed at an enormous cost two special military or war trains, comprising fourteen cars for men, two cars for cooking, two Pullman cars for officers, two cars for arms and stores, and two dining cars The officers' cars are luxuriously fitted out, and contain state rooms, lavatory, smoking room, etc Each train is composed of eleven cars and engine, and gives ample sleeping accommodations for 306 men and 15 officers, although over 100 more men could find room The men's cars are well finished and furnished with modern improvements The kitchen car has all the utensils of a large sized hotel, and requires six cooks and two helpers This one car can turn out over one thousand five hundred meals a day During a trip from Halifax to Vancouver on the war train, 5,500 meals for officers and men were prepared The Canadian Pacific Railway expect to cover the distance from the Atlantic to the Pacific in five and a half days —*British Medical Journal*

Anthrax Septicemia in Man —Blumer (Bulletin of the Johns Hopkins Hospital, vol vi, Nos 54 and 55) describes an unusual case of anthrax septicemia in a man, associated with acute endocarditis and peritonitis due to anthrax bacilli The patient was a laborer 59 years old, employed in a hair factory, who scratched his right eye with his hand while working with hair from South America The following day the eye was swollen and on the second day still more so By means of incision a thin fluid was obtained from the eyelid which was found to contain anthrax bacilli in pure culture Four days after the onset of the swelling, there was some fever while the edema had extended over the face and head, especially the right side A day later, symptoms of interstitial disturbances and of peritonitis developed Death occurred six days after the first sign of any swelling about the eyelids had made its appearance At the autopsy there was found, in addition to the edema of the subcutaneous tissue, a recent vegetative mitral endocarditis, a serohemorrhagic peritonitis, and acute anthrax lesions of the intestines The bacteriologic examination showed anthrax bacilli in the heart's blood, the spleen, the peritoneum, the liver and the lung The especially interesting features in connection with this edematous form of anthrax, which is certainly very unusual in this country, are the clinical symptoms of intestinal lesions and peritonitis and, anatomically, the development of an anthrax endocarditis upon a previously normal valve

A Case of Tuberculous Parenchymatous Keratitis —Zimmermann (*v Graefe's Arch f Opthalm*, Bd XLI, No 1) records a case of parenchymatous keratitis which he observed clinically and subsequently subjected to microscopic examination The clinical course was that of a parenchymatous kerato-iritis, while the microscopic findings showed a well-marked tuberculosis of the cornea, the sclera, and the iris, the posterior portion of the eye being free from tuberculous changes Except some ozena there were no other disturbances in the health of the patient, who was free from heriditary influences The espscially interesting feature in this case is the demonstration of a well marked tuberculosis in the cornea with giant cells and tubercle bacilli In spite of the negative clinical history and objective examination the author believes that the process is not due to a primary, but to a secondary infection of the eye

MISCELLANY

Fatality from Overeating —The New York papers contain an account of a remarkable case of gluttony with a tragic ending Last Sunday a man indulged in seven pickled pig's feet, or "Trilbys," as they are called Twenty-four hours later he was dead, *causa mortis* acute indigestion and colic

Increasing Volume of Medical Work by Missionaries —The Church Missionary Society is one of the largest and best endowed of the organizations of that kind in England and in the world It is constantly making use of the medical man as a missionary and conservator of their forces in the numerous fields in the uncivilized world In 1894 there was a considerable hospital extension, there were 5,000 in-patients under hospital treatment, and 870,000 out patients These are probably the largest annual totals ever presented by this or any other similar society

Tuberculosis Loves a Shining Mark —The fell leveler phthisis has his relentless hold upon the brother of the Czar of all the Russias, and the condition of that prince is precarious The following is the latest item of news by cablegram

Drs Simanovski and Sheresleffski, court physicians, have been summoned to Abbas-Tuman, in the Caucasus, to attend the Grand Duke George, the czarowitz, whose condition has become very much worse The dowager czarina, the grand duke's mother, and her daughter, the Grand Duchesse Xenia, and her husband, are also hastening to the czarowitz' bedside

Bad Basis for Expert Opinion —It is not competent, the Supreme Court of Minnesota holds, in the case of Miller v St Paul City R Co, decided Oct 15, 1895, for a medical expert to give in evidence an opinion as to the cause of a person's physical condition or injuries, based in part upon information which he has derived from private conversations with a third party The opinion rejected in this case was based on an examination made by the expert on the morning of the day it was given and on the statement and the history of of the case which the attending physician furnished him at the time the examination was made

Medical Counts and Barons —Among the titled personages of France who have gone into medical pursuits are Baron Henri de Rothschild, Counts de Sinety and Goyan, and the Duke de Rivoli The *Gaulois* states of the Count de Goyan that he is a prominent royalist, formerly a member of the Chamber of Deputies, and has taken the degree of Doctor of Medicine at the Paris Faculty with the object of giving himself up to the treatment of the sick poor In this, Count de Goyan has followed the example of the Duc de Rivoli (also a former Deputy), Count de Sinety (member of the Jockey Club), and M Rembielinski (well known in Paris society) All these gentlemen began the study of medicine after the age of thirty, and went through the prescribed course, passing their examinations and taking their degree in the ordinary way Baron Henri de Rothschild, who is also preparing for the medical profession, entered himself as a student when very young He has a pronounced taste for surgery, and his present intention is said to be to found a surgical hospital at his own expense

Albany Medical College Alumni Association of Greater New York —A large number of representative medical men, many of them prominent in this and adjoining cities who are graduates of the adjoining Albany Medical College, met at the residence of Dr Horace S Hanks on Madison Avenue on the evening of Dec 5, and organized an association with the above title The following officers were elected President, Dr John W Warner, Vice-President, Dr Horace S Hanks, Secretary, Dr Warren C Spaulding, Assistant Secretary, Dr Robert F McFarlane, Long Island City, Treasurer, Dr Allen S Fitch Governors, Dr Henry F Müller, of Brooklyn Dr L N Lanehart, of Hempsted, L I, Dr Robert E Finney, Dr John A Cutter, of New York Inasmuch as there are over 100 graduates in greater New York these gentlemen feel a certain pride in honoring their alma mater and have taken this course to do so The first annual dinner is to be given Thursday, Jan 9, 1896

Bacteriology and the Farmer —The address on medicine at the annual meeting for 1895 of the Canadian Medical Association was delivered by Dr Edward Farrell, of the Halifax Medical College His discourse led him to a consideration of the rapidly increasing money value of bacteriology as a utilitarian, rather than a purely scientific pursuit In order to show what science can do in building up a trade, he called attention to the extraordinary fact that Denmark at the present time almost controls the market of England in the supply of the best articles of butter The farmers of Denmark have no special advantage over the farmers of England other than this, that in Denmark the government has established scientific schools in which the subject has been closely studied Their bacteriologists have succeeded in isolating the various types of germ that produce special changes in the course of butter production, and by the artificial application of these they control and direct the fermentive process Dr Farrell urged upon the association that, inasmuch as medicine had given bacteriology to the world, the association was in duty bound to urge upon the government the advantages of schools of experimental science constructed upon a liberal plan and generously supported Regarding the details, wherein the bucolic and pastoral interests are linked with the work of the bacteriologist, the address made some reference The interesting whole may be read in the *Montreal Medical Journal* for September, of which the following is a part

In most countries it is the farmer who is the real wealth producer In this country farming is by far the most important industry, to it we look for the production of the food supply of the world When we consider the enormous amount the export of the product of the farm returns to this country we can gather some idea of the immense importance that agriculture is to us It is not necessary, then, to prove that everything that tends to give a more successful yield to the labor of the farmer should claim the special attention of the government I am glad to see that the fact is being recognized, though slowly, that the pursuit of agriculture requires an education in science, and so we find that schools of agriculture, experimental farms, and other means of teaching scientific farming are growing up among us But we are only waking up to the importance of this special scientific training, and though we lead the mother country in this respect (for this subject is to a large extent neglected in England), still we are only making a small part of the effort that should be made in this direction In many European countries, by reason of the fact that science is fostered and supported by the government, its influence upon agriculture, manufacture and the arts is more quickly recognized and applied than in England or America This new science of bacteriology has an especial relation to agriculture As we now know that bacteria have a direct influence upon human life and its diseases, so the life of other animals and plants must be equally under the power of bacterial growth To show the extent to which this is true it is only necessary to name some of the diseases of animals that are known to be due to microörganisms, such as glanders, tuberculosis with its poisoning power on meat and milk, anthrax or wool-sorters' disease, actinomycosis or lump jaw In addition to these there must be other diseases due to bacteria in the various animals used for human food and the raising of our food products in a perfect and healthy form is most important to the trade interests of the country Then there must be the special bacteriology of each plant with its various blights, a thorough knowledge of which must be necessary to successful agriculture The products of the dairy, butter and cheese, are governed in the changes that take place in their manufacture by what is known as fermentation We now know that this fermentation is a complex process brought about in its different forms by various kinds of microörganisms and that each organism has the power of influencing the color, taste and quality of the product"

The Journal of Experimental Medicine (Quarterly) —Messrs D Appleton & Co, of New York, announce that in January, 1896, will appear the first number of *The Journal of Experimental Medicine*, a periodical devoted to original investigations in physiology, pathology, bacteriology, pharmacology, physiologic chemistry, hygiene and practical medicine Dr William H Welch, Professor of Pathology in the Johns Hopkins University, is to be the editor of the new journal and with him will coöperate a board of twelve associate editors as follows,

For Physiology—H P Bowditch, M D, Professor of Physiology, Harvard University, R H Chittenden, Ph D, Professor of Physiologic Chemistry, Yale University, W H Howell, M D., Ph D, Professor of Physiology, Johns Hopkins University

For Pathology—J George Adami, M D, F R C S, Professor of Pathology, McGill University, W T Councilman, M D Professor of Pathologic Anatomy, Harvard University, T Mitchell Prudden, M D, Professor of Pathology, Columbia College

For Pharmacology—John J Abel, M D , Professor of Pharmacology, Johns Hopkins University, Arthur R Cushny, M D , Professor of Materia Medica and Therapeutics, University of Michigan, H C Wood M D , Professor of Materia Medica, Pharmacology and Therapeutics, University of Pennsylvania

For Medicine—R H Fitz, M D Professor of the Theory and Practice of Physic, Harvard University, William Osler, M D , F R C P , Professor of Medicine, Johns Hopkins University, William Pepper, Professor of the Theory and Practice of Medicine, etc , University of Pennsylvania

In addition to the above forty-two gentlemen have consented to act as "collaborators"

Practical Notes

Extirpation of the Spleen—Schalita (*Arch f Kl Chirurg*, Bd XLIX, H 3) describes a case in a woman, 36 years of age, who had always been well, but in whom there had gradually developed a fluctuating tumor in the region of the spleen that filled the larger part of the left half of the abdomen A laparotomy was made in the linea alba, and a large quantity of fluid of a brownish color was evacuated through a trocar Splenectomy was then made and recovery ensued The tumor, which was as large as a man's head, was attached to the inferior surface of the spleen This tumor or swelling is regarded as the result of hemorrhage either from the rupture of an aneurysm of a branch of the splenic artery or from a subcapsular hemorrhage due to other causes, in consequence of which the cyst gradually formed Examination of the blood for some time after the splenectomy did not show any changes in the corpuscles

Treatment of Pneumonia by Digitalis—The author, who has tried in sixty-four cases the treatment of pneumonia by digitalis according to the method of Petresco (de Bucarest), sums up the results he has obtained under the form of the following conclusions

1 Digitalis in large doses forms one of the most powerful therapeutic means against pneumonia

2 It causes a favorable action on the heart, lungs and blood

3 In large doses, digitalis shortens the duration of pneumonia and gives an increase of the leucocytes

4 A dose of one gram of the powdered leaves, and daily doses of four to five grams, are borne without convenience

5 Hydrotherapy (cold water) assists *in these conditions* the action of the digitalis—Naegeli-Akerblom *Centralb f Innere Medic* 1895 No 32 *Revue Internationale* No 22

Diseases of the Prostate—Dr Gabriel Colin ends a general review on the treatment of diseases of the prostate in the *Revue Internationale de Médecine et de Chirurgie Pratiques*, with the following conclusions

1 It is important to be able to promptly diagnose prostatic hypertrophy, and to employ from the beginning such vigorous treatment as will arrest the disease or cause it to retrograde in its progress If the bladder empties itself easily, a medical and hygienic treatment will be sufficient, if it does not, one will have to have recourse to catheterism, repeated frequently, so that the bladder may never become overdistended

2 In case of enormously enlarged prostate, great difficulties in catheterism, false passages, retention with distension, free hematuria, or serious infection, catheterism, Guyon's *mandrin sonde a demeure* will almost always suffice to meet these accidents

3 When it is well proven that these methods have failed or are insufficient (but only then) a more active surgical interference should be attempted We have the choice, according to the case, between the operations that we have studied (exceptional operations for exceptional situations)

Such are, I believe, the rules and the course to be followed by every conscientious physician, bearing in mind that we ought to go from the simple to the compound, commencing by the ordinary and current methods before proceeding to more serious interventions, and that it is the duty of every surgeon to operate without hesitation when he has the proper indications, but always to wait for these

The recent operations, of which we have said some words, do not permit us to lose sight of what we may deduce from the old and methodic treatment, the rules of which have been so masterly studied by Prof Guyon Imbued with these principles, we will be prepared in the present state of urinary surgery and therapeutics to afford the most important aid to our sufferers from prostatic diseases

Poisoning by Creolin—Dr O Pinner, physician to the Jewish hospital at Hamburg, reports in the *Deutsche Medizinsche Wochenschrift* what he believes to be the seventh recorded case of poisoning by creolin His case was that of a female 60 years of age, who had attempted suicide by swallowing seventy-five grams of creolin It was at first not known which of the preparations called creolin had been taken, but the druggist from whom it was purchased subsequently stated that he only sold Pearson's The woman was found unconscious in her room and was taken to the hospital two hours after the attempt on her life She was then comatose, with livid face, moist skin and blue lips, her right pupil was larger than the left, and there was no reflex action on the cornea Her temperature was 36 6 degrees C , her pulse 112 and regular, and her respiration deep and snoring, with tracheal rales In the pharynx there was a large quantity of white mucus, the palatal arches and the posterior wall of the palate were covered by a grey superficial coating There was a strong smell of creolin in the breath By the stomach-pump 300 grams of a thick, grey fluid mixed with mucus were withdrawn, and pressure on the pylorus caused thick, brown drops of pure crolin to come through the tube The first urine (150 grams) was of a light yellow color, without albumin, sugar or indican, the bromin water test showed traces of tar acid in it Microscopic examination revealed nothing abnormal Milk given through an esophageal tube was immediately vomited, but was eventually retained

An hour after admission into the hospital there were well-marked symptoms of shock, for which injections of ether were successfully made There were also copious diarrhea, and the stools had an odor of creolin Some hours later the patient regained consciousness and afterward became better She complained of severe pain in the epigastric region and in the pharynx The urine (80 grams) was now of a dark green color, had an odor of creolin, and contained traces of albumin, by the tribromphenol reaction it was estimated that 7 5 c c of tar substances were present in 100 c c There was no hemoglobinuria, and only a small quantity of leucocytes and red corpuscles and some casts The patient slept very well during the first night, and on the following day there was an obvious improvement, the pulse temperature and respiration being normal, although she still complained of headache, want of appetite and hoarseness, and an erosin on the epiglottis and the arytenoid cartilage was observed with the laryngoscope *On the fourth day there was more* diarrhea, the stools still smelling of tar products The urine continued for a week to be of a green color and contained 1-5 per cent of albumin, with much indican After four weeks the patient was able to leave the hospital in perfect health and did not show *any trace of injury from the poisoning* Notwithstanding the alarming symptoms of the first few hours, the patient very soon recovered, the creolin being obviously removed by the kidneys, which, though disordered for a short time, did not sustain any permanent injury. Creolin, therefore, according to Dr Pinner, must be regarded as a comparatively innocuous substance, although it is remarkable that such extremely severe symptoms followed almost immediately after the poison had been swallowed Creolin, he says, used to be considered harmless because it could not be absorbed by the stomach, but in the above case the gastric juice very soon transmitted the creolin into a form which very quickly passed into the circulation and appeared after two hours in the urine

Death of One of Koch's Earliest Tuberculin Patients—Dr J G Adami, Professor of Pathology at McGill University, has given to the *Montreal Medical Journal*, September, an account of the autopsy made by him upon one of the first patients treated by tuberculin in 1890 The patient was nearly a year under Koch's treatment at the Victoria Hospital of Berlin, and under the usual periodic inoculations with tuberculin he began to regain appetite and body weight, his night-sweats passed away, and his general health appeared to be restored The patient, a native of Finland, aged 33 years, a highly intelligent man, a skilled mechanic in engineering, was taken down for the first time early in 1890 with cough, hemoptysis night-sweats and progressive emaciation The patient from Berlin went to Finland and thence, in 1893, to Montreal He remained apparently in perfect health until January of this year, when the cough returned, and all the old symptoms—night sweats loss of flesh and bodily weakness In March there was an hemoptysis, about half a gallon of blood being lost, there were two other severe hemorrhages later From this time until April 18th, he being now a patient at the Royal Victoria Hospital, there was constant slight expectoration of blood with but little cough On this last date severe hemorrhages recurred, in all about a quart of blood being lost Following upon this, there was rapid loss of vital power, and the patient died ten days later At the autopsy it was noticeable that there was no indication of tuberculosis other than in the lungs, save for some quite recent and minute ulcers in the jejunum and ileum The lungs, however, presented very characteristic tubercular changes There were firm adhesions at both apices—so firm that on the left side the knife had to be employed to separate them Both apices showed old tuberculosis in the shape of well encapsuled caseous masses and small contracted cavities with dense envelopes and smooth but uneven internal aspect In addition, the upper two-thirds of the uppermost lobe of the right lung and the upper half of the upper lobe of the left lung were greatly consolidated contracted and presenting very well marked interstitial fibroid change Here evidently in both apices were to be seen the results of treatment in 1890-91—abundant signs of arrest of the tubercular process It was, however, clear that the process had only been arrested—for the rest of the lung tissue was the seat of numerous rather large miliary tubercles, which from their distribution were broncho pneumonic—distributed along the course of sundry bronchi Injecting the pulmonary arteries with water led to the escape of the fluid through one of the main bronchi of the upper lobe of the left lung Following this up a long cavity was entered into containing a globular laminated clot over what was the seat of rupture of the artery Some difficulty was experienced in finding the actual lesion, the artery filled with thrombus escaping detection for some little time Bringing all these facts together it would seem most probable that the second attack of advancing tuberculosis was not a second infection, or infection anew, but originated in the old arrested foci of the disease, where the process lighting up again in the walls of one of the old incompletely contracted cavities had been followed by dissemination of the virus throughout the air passages, and had prepared the way for rupture of arteries passing along the walls of the cavity

Hospital Notes

The annual report of the Mercy Hospital, conducted by the Sisters of Mercy, in Chicago, shows that 1,378 patients have been treated during the year ——At a meeting of the trustees of the new Western Hospital for the Insane held in Springfield, Ill, Dec 9, it was decided to erect the institution in Rock Island The site is said to be the handsomest one for hospital purposes in the State

Society Notes

The Third International Congress of Psychology will take place at Munich, Aug 4-7, 1896 President, Prof Stumpf, Berlin, Vice President, Prof Lipps, Munich, General Secretary, Dr Schrenck-Notzing, Munich The International Committee of Organization includes the names of many of the most distinguished psychologists of the world Bain, of Scotland, Baldwin, of Princeton, Bernheim, of Nancy Delboeuf, of Brussels Donaldson, of Chicago, Ebbinghaus, Breslau, Ferrier, London, Fullerton, Philadelphia, Stanley Hall, Worcester, Hitzig Halle, James, Harvard, Lehmann, Copenhagen, Liégeois, Nancy, Witmer, Philadelphia, Mendelssohn, St Petersburg, Monokow, Zurich, Morselli, Genoa, Myers, London, Newbold, Philadelphia, Preyer, Wiesbaden, Richet Paris, Schäfer, London, Sedgwick Cambridge, Sully, London, Ward, Cambridge The invitation to membership is extended to all interested in psychology, and the membership fee is 15 marks The work of the Congress is to be carried on in four Sections, viz Psychophysiology, including cerebral anatomy and physiology, and psychophysics, Normal Psychology, Psychopathology, Comparative Psychology Those interested in the work of the Congress and desirous of learning the details of the preliminary program will receive the invitation and announcement on sending name and address to Dr C G Chaddock, 610 N Garrison Avenue, St Louis, Mo

Mitchell District Medical Society —The midwinter meeting of this Society will be held at Bloomington, Ind, Thursday and Friday, Dec 26 and 27, 1895 A sufficient number of papers have been promised to insure the success of the meeting The address on the evening of the 26th will be delivered by Prof Daniel R Brower, of Chicago, on ' The Marks of Disease in the Habitual Criminal and the Remedy, Illustrated by the Stereopticon " The program will be issued Dec 20 ——The annual meeting of the Syracuse, N Y Academy of Medicine was held Dec 3 The following officers were elected for the ensuing year President, John Van Duyn, First Vice President, Eli Van de Warker, Second Vice President, D M Totman, Secretary, T H Halsted, Treasurer E L Mooney ——The annual meeting of the Baltimore and Ohio Association of Railway Surgeons was held in Pittsburg Dec 3 The following officers were elected President, J M Spear, Cumberland, First Vice President, S S Good, Meyersdale, Second Vice President P B Short, Secretary and Treasurer, J A McKean ——The monthly meeting of the McLean County Medical Society was held in Bloomington, Ill ——The fifty-first semi annual meeting of the Northwestern Ohio Medical Association was held at Findlay, Ohio, Dec 12 and 13 ——The sixty-first annual meeting of the Fox River Valley Medical Association was held in Aurora, Ill Dec 10 Officers were elected as follows President, H W Richardson, Marengo, Vice President M M Robbins, Aurora, Secretary, J W Bumstead, Dundee The next meeting will be held in Elgin

Detroit Notes

The Children's Free Hospital is now assured, thanks to the $125,000 that the noble philanthropic citizen Mr Hiram Walker gave, which gift he has set aside for the purchase of the ground and building, and whatever surplus remains, to be devoted to current expenses The Children's Free Hospital Association was first organized in 1886 and was connected with Harper Hospital, but as the facilities were inadequate, it was moved to a large building corner of Seventh and Fort Streets The Association is under the government of a Board of lady residents well-known in the noble work of charity, assisted by an Advisory Committee of prominent business men The affairs of the hospital are under the direction of a Superintendent assisted by a head nurse A house physician resides in the hospital During the first year, the hospital cared for 80 children, second year, 136, increasing each year until the number of admissions reached 259 the past year The percentage of children discharged cured each year has averaged from 50 to 60 per cent of admissions improved from 20 to 25 per cent, unimproved about 5 per cent, while the death rate has never exceeded 10 per cent of admissions, which is a strong argument in favor of an institution of this character if one were needed, when it is taken into consideration that the majority of children treated in it would drag along without any medical treatment or tender care bestowed upon them until death relieved them of their misfortune The medical staff is composed of prominent physicians of the city, each a specialist, with Dr C A Devendorf as chief of staff In connection with the hospital there is an outdoor clinic, established in 1893, where patients not sick enough to be admitted to the hospital, yet needing care, are treated free of charge

The proportion of children admitted this year exceeds the average and at present there are 32 children in the hospital under treatment and convalescing, while over 250 have received treatment in the outdoor clinic since Jan 1, 1895 The new hospital, now almost completed, has all modern conveniences The boiler-room being entirely separate from the main building, and all rooms will receive the sunlight The hospital will accommodate 64 children, and will be ready for occupancy April 1, 1896

The Wayne County Medical Society at its regular meeting Thursday, Dec 5, listened to a very interesting paper on "Anesthetics," by Dr Kenneth Gunsolus, in which he took up the discovery, history and use of anesthetics The majority of the members were of the opinion that chloroform was the preferable drug, excepting in such cases as it was counter-indicated

Detroit Medical and Library Association —At the regular meeting of this Association, the secretary, Dr Anderson, read a paper by Dr Charles A Oliver, of Philadelphia, entitled, "The Action of Hydrobromate of Scopoleine Upon the Iris and Ciliary Muscle" Dr Daniel La Ferte read a paper entitled, "Club Foot" The doctor also exhibited a patient upon whom he had operated by the Phelp's method

Health Office Report for week ending Dec 7, 1895 Deaths under 5 years, 31, total 78 Births Male 43, female 41, total 84 Contagious diseases Diphtheria Last report 38, new cases 26, recovered 25, died 9, now sick 30 Scarlet fever Last report 19, new cases 11, recovered 9, died none, now sick 21 Small-pox Last report 2, new cases none, recovered 1, died none, now sick 1

St. Louis Notes

Weekly Report of the Health Office —Report shows a continuance of the direful effect of diphtheria in the occurrence of 17 deaths, and 4 deaths attributable to croup There were 2 deaths from scarlatina, 4 from typhoid, and 1 from cerebro-spinal fever during the week

The St Louis Medical Society —The program for Dec 7 announced a continuance of the discussion of the subject of hematomyelia, demonstrations of a method of diagnosticating diabetes by the condition of the blood, by Dr Ludwig Bremer, and a paper on "How to Cure Acute Middle Ear Disease more Quickly," by Dr Robert Barclay Dr Bremer's demonstration was most interesting as bearing upon the possibility of detecting diabetes under circumstances where there was an object in concealing the disease, as in examination for life insurance The method consists of a staining of the blood which produces a marked macroscopic differentiation between normal and diabetic blood It was claimed that after sugar had ceased to appear in the urine as a result of dietetic measures, by this method it could still be detected in the blood

The City Board of Health has framed a resolution looking to the appointment of a corps of competent physicians whose duty it shall be to make daily visits to the public schools and examine all ailing children, and children that come from homes where sickness exists The prevalence of diphtheria is taken as the warrant for this measure

The Health Commissioner has caused to be printed for gratuitous distribution a pamphlet devoted to a popular exposition of the means of preventing, avoiding, and suppressing communicable diseases, with a resumé of the laws respecting the duties of physicians when in attendance upon cases of contagious disease, as well as of the city ordinances related to the duties of the principals and teachers of private and public schools in such cases Diphtheria is first given attention, and then follow scarlet fever, tuberculosis, smallpox and typhoid fever The public diffusion of knowledge of the duty of physicians and teachers in cases of contagious disease will assist both classes in the performance of what is often a disagreeable task because of the frequent dissatisfaction arising out of the necessity to placard a house or to exclude children from school The pamphlet is most opportune, and can not fail to have a decided influence now and hereafter in restricting the spread of disease

The Missouri State University Laboratory is now well started in the work of producing the antitoxin of diphtheria, under the approval of the State Board of Health The Board is also taking steps to collect statistics concerning diphtheria and the results of the new treatment

The Marion Sims College has been made defendant in a suit to recover anatomic and pathologic specimens, by Dr. Louis Bauer The college asserts that Dr Bauer donated the specimens in question to the college museum, and therefore refuses to release them until ownership is proved

The Barnes Medical College has broken ground on Garrison Avenue for its new building

A New Law concerning the punishment of crimes committed by persons under the age of 18 has received its first application here during the week, and has given rise to some discussion The law is framed to prevent the commitment of youthful criminals to the penitentiary, and to place them in the Reform Schools There can be no question of its general wisdom in cases of minor crimes, but it is pointed out that a boy just under 18 can commit murder in the second degree, and the crimes of arson, criminal assault, and robbery in the first degree, and his punishment be fixed by the law at only three years in the Reform School

The Annual Reunion of the editorial staff of the *Medical Fortnightly* will take place at the Mercantile Club, Thursday evening, Dec 12

Washington Notes

Weekly Report of the Health Office —The report of the Health Office for the week ending Nov 30 is as follows· Number of deaths (still-births not included) White, 63, colored, 44, total, 107 Death rate per 1,000 per annum White, 17.5, colored, 26.0, total, 20.2 Death rate per 1,000 per annum corresponding week last year, 16.2 A slight rise took place in the number of deaths reported at the Health Department during last week as compared with the preceding week The mortality was 107, as against 99 reported the week before The annual death rate was 20.2, which is 3.6 below the annual average for the District of Columbia The notable feature of the week's health history is the continued abeyance of the dangerous contagious diseases, there having been but one death from diphtheria The mortality from brain maladies reached 10, of which 5 were from apoplexy There was a material increase in the deaths from acute lung diseases, 16 of them being from pneumonia and 7 from congestion of the lungs The deaths from typhoid fever were 4, as compared with the same number the preceding week, while in the corresponding week of last year, there were 5 deaths Aside from these exceptions, the general health of the city is favorable, with an annual death rate materially below the normal

Gold Medal for Dr Taylor —Dr Thomas Taylor, of this city, has recently received through the Georgetown custom house a gold medal, which was awarded him by the International Society of Hygiene in recognition of the value of his original investigations on butters and fats and the edible mushrooms of the United States in the interest of hygiene Dr Taylor furnished by request a paper which was read at the last annual meeting of the society, held in Rome, Italy, 1894

Washington Board of Trade —At a recent meeting of the Board of Trade Dr Samuel C Busey was elected a member of the Board of Trustees Dr W P C Hazen has been added to the Committee on Public Health Acting on the recommendation of the Committee on Public Health the Board has appointed a Special Committee to prepare a sanitary code for the District The medical men on the committee are Drs Geo L Magruder, Chairman, and Health Officer W C Woodward

Whisky Inspection —The chemist of the District has completed an analysis of fifty specimens of whisky secured by the Excise Board The research shows an entire absence of

and investigation here, but only the practical study of the chemic processes taking place in the human body in health and disease Adjoining the chemic room on the north is the room devoted to bacteriology, the most active department on account of the importance which bacteriologic investigation has attained in recent years Close attention will be devoted in this work to a study of the conditions under which bacteria thrive and the influences that can be brought to bear to cause their destruction The room is equipped with microscopes of the highest power, and large incubating ovens in which the microorganisms can be safely cultivated The rooms of the Director and Assistant Director, on the second floor, will be used as offices and for their own personal studies On the third floor there is a single large room which will be used in teaching the post-graduate work requiring the aid of the laboratory There are four rooms on the fourth floor One of them is fitted up as a library, and will be used as a meeting-room for the Fellows and Associates of the laboratories At the head of the staff is Dr William Pepper, Director The Assistant Director is Dr Alfred Stengel, and instructor in medicine and assistant physician to the University Hospital The members of the staff are trained specialists, and are as follows Chemical Department, Dr Casper Wistar Miller and Dr George Stanley Woodward, Microscopic Department, Dr Alonzo E Taylor, Dr Thomas S Kirkbride, Jr, Dr J Dutton Steele, Bacteriologic Department, Dr Samuel S Kneass, Physical Department, Dr Joseph Saylor, Dr David L Edsall, Dr Samuel McClintock Hamil

A BANQUET and testimonial was given in honor of Dr John S Billings, who has recently removed his residence to this city and been appointed to the new chair of Hygiene in the Faculty of the University of Pennsylvania, he is also Director of the University Hospital The dinner was given at the Hotel Bellevue, Philadelphia, Nov 30, 1895. Dr L Wier Mitchell presided as chairman and speeches were made by Drs J M DaCosta, S Weir Mitchell, John S Billings, J R Chadwick of Boston, Robert Fletcher of Washington, A Jacobi of New York, and William Osler of Baltimore A list of foreign contributors were read and a cheque for the amount of $10,000 was given to Dr Billings with some most appropriate remarks by the Chairman

THE annual meetings of the Geological Society of America, the American Society of Naturalists, the American Physiologic Society, the Association of American Anatomists, and of the American Psychological Association will be held in Philadelphia, on Dec 26, 27 and 28, in the halls of the University of Pennsylvania Prof E D Cope is Chairman of the Committee on Arrangements, Dr Horace F Jayne Treasurer, and Persifer Feazle Secretary The remaining members being Drs Harrison Allen, Edward J Reichert, and W R Newbold

AN UNUSUAL case was reported to the Academy of Surgery by Dr Thos G Morton at its December meeting A healthy woman, 34 years of age, engaged in house work, sneezed violently and soon afterward appeared much prostrated A few hours later she was taken to the Pennsylvania Hospital in a state of collapse, and she soon died At the autopsy, there was found in the superior aspect of the stomach, near the smaller curvature, a ragged opening as large as a five-cent piece, but without much expulsion of contents of stomach owing to location An unhealed ulcer of smaller size was also found in the vicinity of the first one There had probably been adhesion between the stomach and diaphragm as a result of the ulceration process, and this adhesion was torn apart by the violence of the movement of the diaphragm in the art of sneezing

AT THE College of Physicians, Dec 4, Dr John B Deaver read a communication on "Some Salient Points in the Diagnosis, Pathology, and Treatment of Appendicitis" The paper was based upon two hundred operations for appendicitis performed by the lecturer with only two deaths, both of which occurred in the first series of one hundred cases, giving a mortality of 1 per cent after abdominal section for appendicitis He bases the diagnosis upon the three cardinal points of suddenness of onset, rigidity of muscles upon right side, and pain and tenderness in right inguinal region He had found some cases with pain complained of on left side, and in these cases he had found the appendix toward the left side of the pelvic region The abscess may discharge into the bladder, therefore, the presence of pus in the urine does not always decide the diagnosis in favor of pyonesis When the tip of the appendix occupies the pelvis, symptoms of vesical irritability occur and are of diagnostic value He advocated early operation with removal of appendix before the stage of pus formation He did not think it wise to operate upon a patient in collapse, but where an operation is to be done he advised a thorough operation with removal of the appendix in all cases The practice of simply opening the abscess and draining, he pronounced incomplete surgery He said in conclusion that there is no medical treatment that will cure appendicitis, and quoted Osler's remark that, in these cases, "the surgeon is often called too late but never too early"

THE PUBLIC SERVICES

Surgeon George W Stoner M -H S, sailed for Europe on the *Kaiser Wilhelm II*, last week He will be absent several months

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from November 30 1895 to December 6 1895

Capt William H Arthur Asst Surgeon, is relieved from duty at Ft Columbus, N Y, and ordered to Ft Myer, Va, for duty

First Lieut John S Kulp, Asst Surgeon, leave of absence granted is hereby extended one month

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending December 7, 1895

Asst Surgeon George C Hubbard detached from instruction at the Naval Laboratory, New York, and ordered to the 'Vermont'

P A Surgeon E R Stitt, detached from the 'New York," and ordered to the coast survey steamer "Bache"

P A Surgeon G H Barber, detached from the "Bache,' and ordered to the "New York"

Marine Hospital Changes Official list of changes of station and duties of Medical Officers of the U S Marine Hospital Service for the fifteen days ended November 30 1895

Surgeon C S D Fessenden placed on waiting orders, Nov 22, 1895

Surgeon F W Mead, granted leave of absence for thirty days, Nov 21, 1895

P A Surgeon W P McIntosh, to proceed from Boston, Mass, to Portland, Me for temporary duty, Nov 25, 1895

P A Surgeon W J Pettus, relieved from duty at Buffalo, N Y, and directed to proceed to Cape Charles Quarantine, and assume command of Station, Nov 16 1895

P A Surgeon G M Magruder, granted leave of absence for thirty days, Nov 20 1895

P A Surgeon T B Perry, relieved from command Cape Charles Quarantine and directed to proceed to Buffalo, N Y, and assume command of service Nov 16, 1895

P A Surgeon W G Stimpson, granted leave of absence for thirty days Nov 20 1895

Asst Surgeon I E Cofer, placed upon waiting orders from Dec 1, 1895, Nov 21 1895

Asst Surgeon J A Nydegger, when relieved from temporary duty at Mobile, Ala to rejoin station at Savannah, Ga, Nov 27, 1895

Asst Surgeon W I S Stewart, granted leave of absence for fourteen days, Nov 29 1885

Asst Surgeon E K Sprague relieved from temporary duty at Key West Quarantine and directed to rejoin his station at Mobile, Ala, Nov 27 1895

Asst Surgeon Emil Prochazka to proceed from Detroit, Mich, to Buffalo, N Y, for temporary duty, Nov 16, 1895

Asst Surgeon J B Greene, granted leave of absence for thirty days, Nov 20, 1895

ADDRESS

THE INTERNATIONAL SCIENTIFIC LANGUAGE

The Annual Address read before the Association of American Medical Editors, May 7, 1895

BY JOHN B HAMILTON, M D, LL D
CHICAGO

Gentlemen of the Association —As I look around me to-day, and see the distinguished membership, I can only say that he who would interest this audience, or inject into our annual meeting a thought out of the common run, must have either extraordinary ability or remarkably good luck I shall therefore only attempt to discuss a question which has been more or less prominent and with which all are more or less familiar

All are not born lexicographers like our brother Dunglison, nor do they achieve lexicography like our brother Foster, or our Vice President Gould, and as for having it thrust upon them—why, that depends on the enterprise of our friends the publishers, and the same may be said of philologists Most medical editors are more concerned with the simple proposition, that in all cases the "nominative case shall govern the verb" in the articles they publish, than in that deeply interesting philologic problem of whether the Chinese and North American, or the Semitic, Indo European and Turanian languages were first to follow the hieroglyphs

The truth is that the progress of science has demonstrated the great advantage—nay, the necessity—for an easier means of communication between the scientific men of the world, than is now found

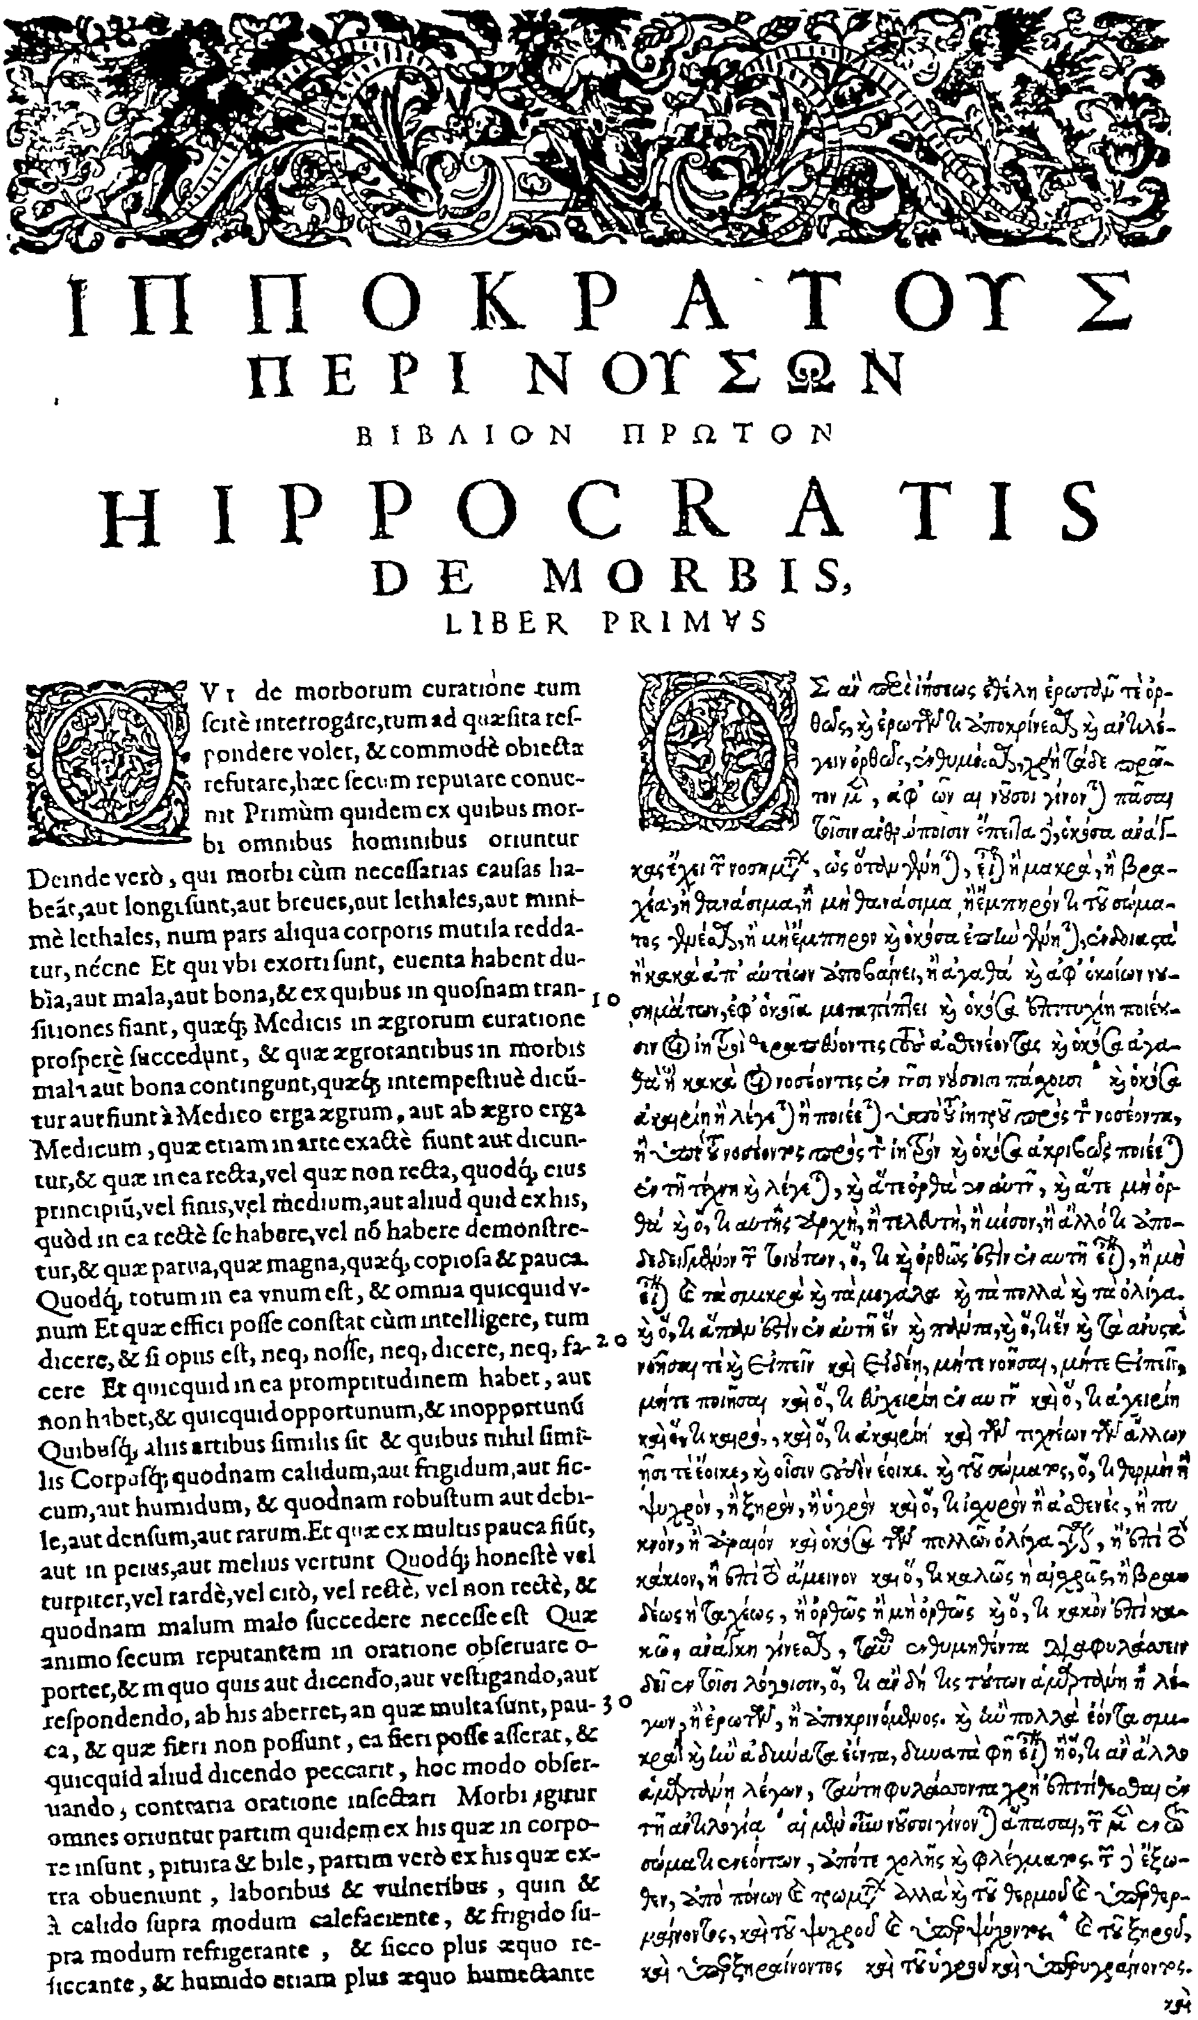
Although at some of our International Medical Congresses the number of official languages have been reduced to three, viz English, French and German, yet even that limitation was not narrow enough to bring all together, for comparatively few are able to understand more than two spoken languages It is granted that it may be done, and that here and there are brilliant linguists in our profession, who not only understand and speak two, but four or five, like our Surgeon General Sternberg of the Army, or Gihon of the Navy, or the laryngologist Braun of Trieste, who seems equally familiar with five languages This admission of possibility does not imply that it is likely that any considerable number of scientific men will ever set themselves to work to memorize the immense vocabulary that is necessary to accomplish such a feat, and there can be no question but one's time might be employed to better advantage if we can only agree upon what particular language we shall adopt

Unfortunately, there are so many side issues The old Adam in men, which makes them selfish, and which selfishness is so often mistaken for patriotism, makes each nation so tenacious, so absolutely certain that each has the very best language that can by any possibility be constructed, that they are but little nearer coming together on the point than they were at the time of the confusion of tongues at the Tower of Babel—and the seeming impossibility of agreement led to the construction of an alleged language called *Volapük* which, up to this time, has been spoken by nobody and only written by doctrinaires The Volapuk is a language that to most men is at once so difficult and forbidding, that it has made little or no progress since first invented by Herr Schleyer in 1879 But when we reflect that it has taken centuries to create the existing languages, we see that the propagandists of Volapük have more to contend against than intrinsic ugliness, lack of harmony or difficulty of acquirement

This inherent slowness necessarily dampens our personal interest, for no one can take a very deep interest in that very remote posterity that may speak Volapuk and enjoy it Naturally then, we turn to the question of whether we shall use a living or a "dead" language The objection to the use of a living language is mainly that it is difficult to secure agreement, although the diplomatists long ago settled the matter by making French the universal language of diplomacy The fate of nations and their international relations are too important to be trifled with, and we see that with few exceptions all diplomatic conventions hold their proceedings in the French language

Dr Achille Rose in this country, and several medical authors in Europe favor Greek The Greek language has constantly undergone changes from its origin As a population has always remained in Greece, it is a mistake to consider Greek as a "dead" language The idea of change is essential to our idea of life, from the seed to the plant in the vegetable world, from the egg to the animal in the animal world, and in language a constant change, as restless, as varying as the waves of the sea This change in the Greek is well shown in the cuts I show you here Plate 1, p 1066, is the fac simile of the first page of the chapter of Hippocrates' "De Morbis," as published by Chouer in Geneva in 1657, and plate 2 is the chapter of Aretæus of Cappadocia, "De Causis et Signis Acutorum Morborum," published at Leyden, 1730, and plate 3 is from the recent work of Georgios A Kostomoire, published at Athens, 1887

This last work is on "The Ophthalmology and Otology of the Ancient Greeks, from the Most Ancient Times Down to that of Hippocrates" One would suppose on general principles, that Hippocrates was ancient enough for all ordinary purposes, but Kostomoire has shown us something of the immense riches of medical literature anterior to Hippocrates It is as well to remove Greek from the list of dead languages, because the Greek language has had a continuous existence from the days of Homer That



ΙΠΠΟΚΡΑΤΟΥΣ
ΠΕΡΙ ΝΟΥΣΩΝ
ΒΙΒΛΙΟΝ ΠΡΩΤΟΝ

HIPPOCRATIS
DE MORBIS,
LIBER PRIMVS

QVI de morborum curatione tum ſcitè interrogare, tum ad quæſita reſpondere volet, & commodè obiecta refutare, hæc ſecum reputare conuenit. Primùm quidem ex quibus morbi omnibus hominibus oriuntur. Deinde verò, qui morbi cùm neceſſarias cauſas habeat, aut longi ſunt, aut breues, aut lethales, aut minimè lethales, num pars aliqua corporis mutila reddatur, néene. Et qui vbi exorti ſunt, euenta habent dubia, aut mala, aut bona, & ex quibus in quoſnam tranſitiones fiant, quæq; Medicis in ægrorum curatione proſperè ſuccedunt, & quæ ægrotantibus in morbis mali aut bona contingunt, quæq; intempeſtiuè dicuntur aut fiunt à Medico erga ægrum, aut ab ægro erga Medicum, quæ etiam in arte exactè fiunt aut dicuntur, & quæ in ea recta, vel quæ non recta, quodq; eius principiũ, vel finis, vel medium, aut aliud quid ex his, quòd in ea rectè ſe habere, vel nõ habere demonſtretur, & quæ parua, quæ magna, quæq; copioſa & pauca. Quodq; totum in ea vnum eſt, & omnia quicquid vnum. Et quæ effici poſſe conſtat cùm intelligere, tum dicere, & ſi opus eſt, neq; noſſe, neq; dicere, neq; facere. Et quicquid in ea promptitudinem habet, aut non habet, & quicquid opportunum, & inopportunũ. Quibuſq; alijs artibus ſimilis ſit & quibus nihil ſimilis. Corporiſq; quodnam calidum, aut frigidum, aut ſiccum, aut humidum, & quodnam robuſtum aut debile, aut denſum, aut rarum. Et quæ ex multis pauca fiũt, aut in peius, aut melius vertunt. Quodq; honeſtè vel turpiter, vel tardè, vel citò, vel rectè, vel non rectè, & quodnam malum malo ſuccedere neceſſe eſt. Quæ animo ſecum reputantem in oratione obſeruare oportet, & in quo quis aut dicendo, aut veſtigando, aut reſpondendo, ab his aberret, an quæ multa ſunt, pauca, & quæ fieri non poſſunt, ea fieri poſſe aſſerat, & quicquid aliud dicendo peccarit, hoc modo obſeruando, contraria oratione inſectari. Morbi igitur omnes oriuntur partim quidem ex his quæ in corpore inſunt, pituita & bile, partim verò ex his quæ extra obueniunt, laboribus & vulneribus, quin & à calido ſupra modum calefaciente, & frigido ſupra modum refrigerante, & ſicco plus æquo reſiccante, & humido etiam plus æquo humectante

ΟΣ ἂν περὶ ἰητρικῆς ἐθέλῃ ἐρωτᾷν τε ὀρθῶς, καὶ ἐρωτῶντι ἀποκρίνεσθαι καὶ ἀντιλέγειν ὀρθῶς, ἐνθυμεῖσθαι χρὴ τάδε· πρῶτον μὲν, ἀφ' ὧν αἱ νοῦσοι γίνονται πᾶσαι τοῖσιν ἀνθρώποισιν· ἔπειτα δὲ, ὁκόσα ἀναγκαίως ἔχει τὸ νόσημα, ὡς ὅταν γένηται, εἶναι ἢ μακρὰ, ἢ βραχέα, ἢ θανάσιμα, ἢ μὴ θανάσιμα, ἢ ἔμπηρόν τι τοῦ σώματος γενέσθαι, ἢ μὴ ἔμπηρον· καὶ ὁκόσα ἐπὴν γένηται, ἐνδοιαστὰ ἢ κακὰ ἀπ' αὐτέων ἀποβαίνει, ἢ ἀγαθά· καὶ ἀφ' ὁκοίων νοσημάτων, ἐφ' ὁκοῖα μεταπίπτει· καὶ ὁκόσα ἐπιτυχίῃ ποιέουσιν οἱ ἰητροὶ θεραπεύοντες τοὺς ἀσθενέοντας· καὶ ὁκόσα ἀγαθὰ ἢ κακὰ οἱ νοσέοντες ἐν τῇσι νούσοισι πάσχουσι· καὶ ὁκόσα ἀκαιρίῃ ἢ λέγεται ἢ ποιέεται ὑπὸ τοῦ ἰητροῦ πρὸς τὸν νοσέοντα, ἢ ὑπὸ τοῦ νοσέοντος πρὸς τὸν ἰητρὸν· καὶ ὁκόσα ἀκριβῶς ποιέεται ἐν τῇ τέχνῃ καὶ λέγεται, καὶ ἅ τε ὀρθὰ ἐν αὐτῇ, καὶ ἅ τε μὴ ὀρθά· καὶ ὅ, τι αὐτῆς ἀρχὴ, ἢ τελευτὴ, ἢ μέσον, ἢ ἄλλο τι ἀποδεδειγμένον τῶν τοιούτων, ὅ, τι καὶ ὀρθῶς ἐστιν ἐν αὐτῇ εἴρηται, ἢ μὴ εἴρηται· καὶ τὰ σμικρὰ καὶ τὰ μεγάλα, καὶ τὰ πολλὰ καὶ τὰ ὀλίγα. καὶ ὅ, τι ἅπαν ἐστὶν ἐν αὐτῇ ἓν καὶ πάντα, καὶ ὅ, τι ἓν καὶ τὰ ἀνυστὰ νοῆσαί τε καὶ εἰπεῖν καὶ εἰδέναι, μήτε νοῆσαι, μήτε εἰπεῖν, μήτε ποιῆσαι· καὶ ὅ, τι εὐχερείη ἐν αὐτῇ· καὶ ὅ, τι ἀγχιείη καὶ ἐν τι καιρὸς, καὶ ὅ, τι ἀκαιρίη· καὶ τῶν τεχνέων τῶν ἄλλων ᾗσι τε ἔοικε, καὶ οἷσιν οὐδὲν ἔοικε. καὶ τοῦ σώματος, ὅ, τι θερμὸν ἢ ψυχρὸν, ἢ ξηρὸν, ἢ ὑγρὸν· καὶ ὅ, τι ἰσχυρὸν ἢ ἀσθενὲς, ἢ πυκνὸν, ἢ ἀραιόν· καὶ ὁκόσα τῶν πολλῶν ὀλίγα γίνεται, ἢ ἐπὶ τὸ κάκιον, ἢ ἐπὶ τὸ ἄμεινον· καὶ ὅ, τι καλῶς ἢ αἰσχρῶς, ἢ βραδέως ἢ ταχέως, ἢ ὀρθῶς ἢ μὴ ὀρθῶς· καὶ ὅ, τι κακὸν ἐπὶ κακῷ ἀνάγκη γίνεσθαι, ταῦτα ἐνθυμηθέντα διαφυλάσσειν δεῖ ἐν τοῖσι λόγοισιν, ὅ, τι ἂν δή τις τούτων ἁμαρτάνῃ ἢ λέγων, ἢ ἐρωτῶν, ἢ ἀποκρινόμενος. καὶ ἢν πολλὰ ἐόντα σμικρὰ καὶ ἢν ἀδύνατα εἴπῃ, δυνατὰ φῇ εἶναι ἢ ὅ, τι ἂν ἄλλο ἁμαρτάνῃ λέγων, ταῦτα φυλάσσοντα χρὴ ἐπιτίθεσθαι ἐν τῇ ἀντιλογίᾳ. αἱ μὲν οὖν νοῦσοι γίνονται ἅπασαι, τῶν μὲν ἐν τῷ σώματι ἐνεόντων, ἀπό τε χολῆς καὶ φλέγματος· τῶν δὲ ἔξωθεν, ἀπὸ πόνων καὶ τρωμάτων· ἀλλὰ καὶ τοῦ θερμοῦ καὶ ὑπερθερμαίνοντος, καὶ τοῦ ψυχροῦ καὶ ὑπερψύχοντος· καὶ τοῦ ξηροῦ, καὶ ὑπερξηραίνοντος καὶ τοῦ ὑγροῦ καὶ ὑπερυγραίνοντος.

CAPITOLO VI

PRESSIONE ATMOSFERICA

§ 1

La pressione atmosferica è uno degli elementi più importanti nella
costituzione del clima, epperò ha un grande significato fisiologico Sco-
perto il barometro, si potette constatare che in ragione noi ci eleva-
mo nell aria avvertiamo un abbassamento nella colonna barometrica,
esattamente proporzionato al peso degli strati d aria sottostanti Di tal
che si son potute osservare le differenze della pressione, alle quali sono
sottoposti tutti i corpi situati alla superficie del globo, ed in ispecie
il peso totale che il corpo umano sopporta, sotto la pressione di una
colonna d aria equivalente a 701^{mm}, che è il massimo, tenendo conto
dell altezza normale del barometro al piano del mare Considerando la
mobilità della grande massa aerea, e le continue vicende meteoriche
cui la medesima va soggetta, si sarebbe indotto a credere alla facile
mutabilità della pressione atmosferica Eppero, dice Lombard¹, esiste
per ciascuna località un altezza normale del barometro, e le oscilla-
zioni della colonna mercuriale sono di due ordini differenti le une si
presentano sotto forma periodica, e si riproducono in certe ore del
giorno, in certi mesi o stagioni, ed in certe circostanze di altezza
e di latitudine, altre al contrario, comunque si mostrino anche con
una certa periodicità in certe circostanze, di cui faremo parola, sono
pertanto essenzialmente irregolari, e molto più transitorie, essendo
sotto la dipendenza immediata dei venti e della umidità atmosferica
Intanto è mestieri si conosca che, tranne le grandi differenze che si
osservano nella colonna barometrica per le altezze, o nel caso di in-
tense correnti di venti, o di terremoti, o di tempeste, le modificazioni
della pressione atmosferica, le quali non sorpassino pochi millimetri,
non esercitano che una debole influenza sulla nostra economia
1°) Nello scopo di avere una media esatta dell altezza barometrica
normale si possono tener presente certe ore, le quali rappresentano le

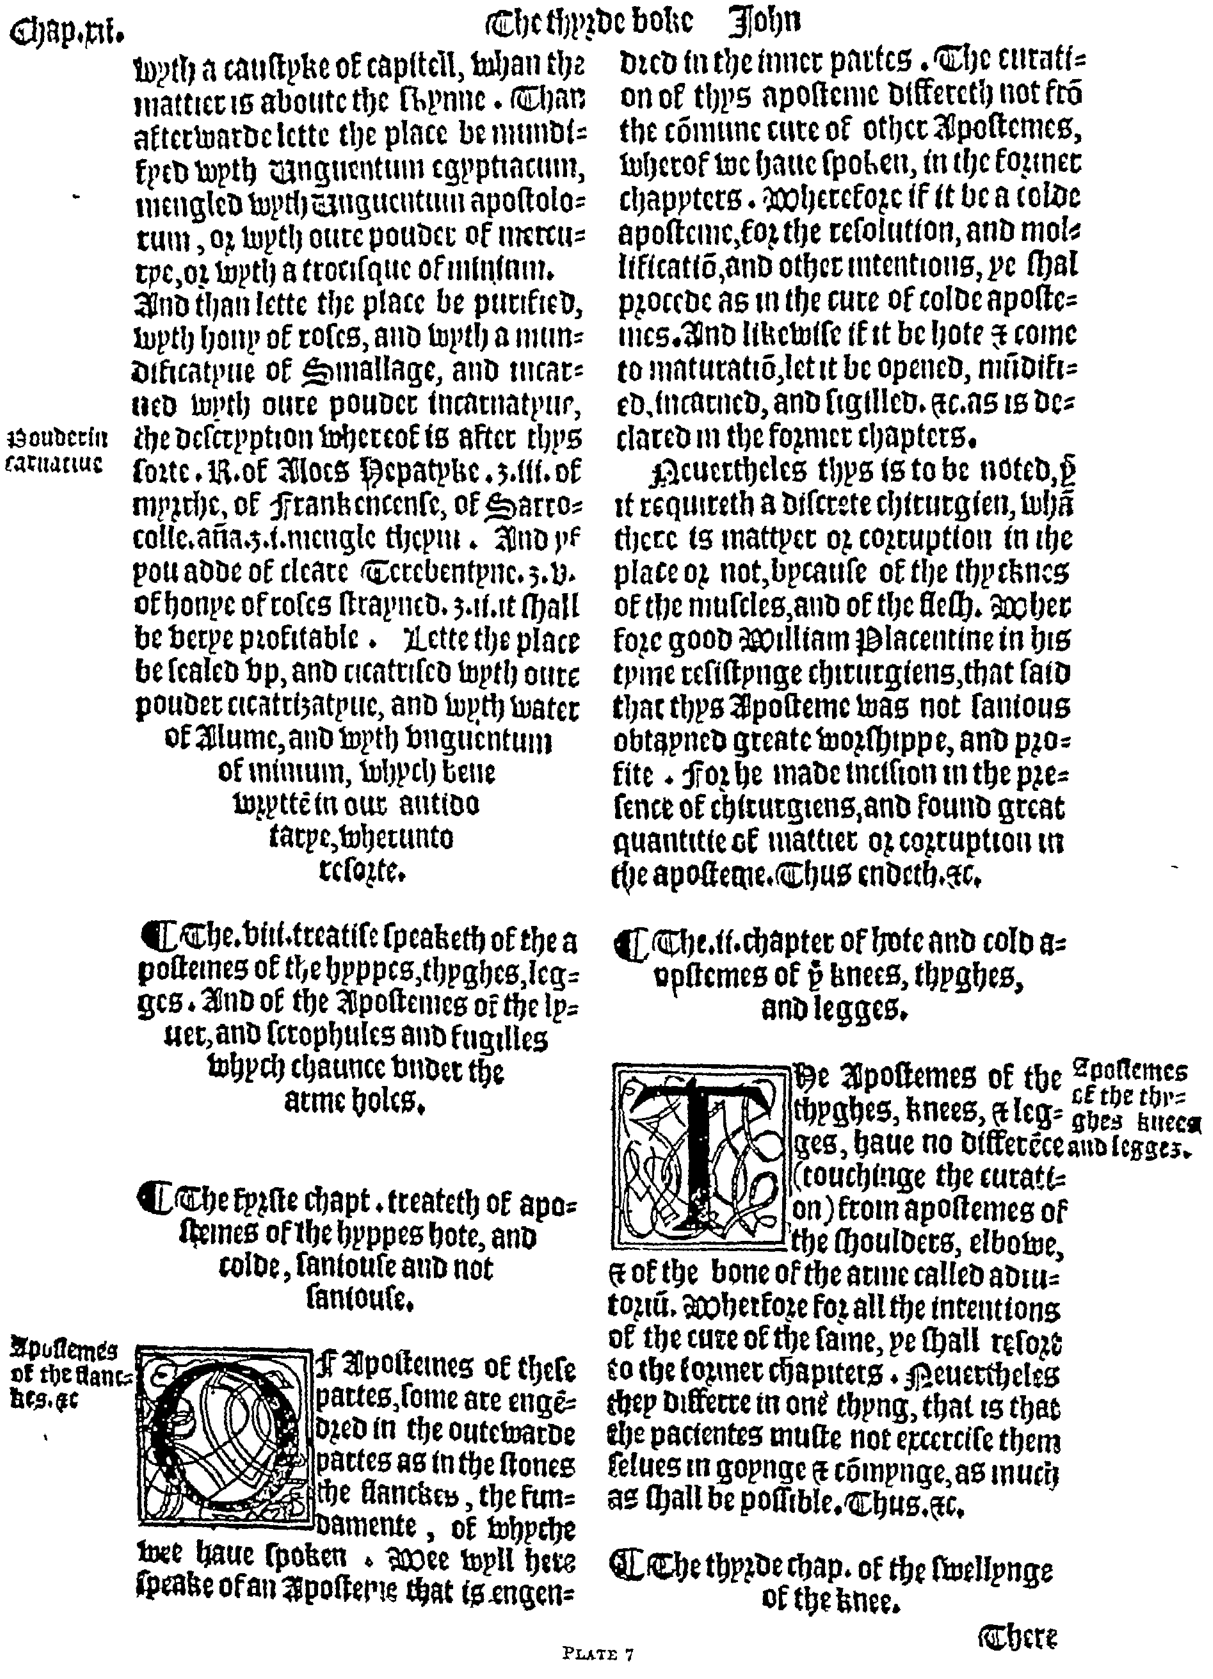
Plate 6

there have been many changes, that it is still changing, is positive proof that it is alive and takes note of the changes and mutations brought about by science and the flight of time

Dr Rose, whose enthusiasm for the Greek language seems stimulated by the romantic history of that interesting people, seems to think that we should adopt modern Greek because of that history The reason is not a valid one, the only real question before the scientific world is What language can we adopt as that one which will require the least expenditure of time and energy consistent with accurate transmission of ideas? The question of history has nothing to do with it. We are to consider the actual need and the best means of supplying it. Shall we return to Latin? Here there is no change and for nearly one thousand seven hundred years that was the scientific language of the world. Less than two centuries have elapsed since Latin ceased to be the common language of science. It was abandoned simply because it was inelastic, it failed to accommodate itself to the new inventions and discoveries which created a new world to be named, and myriads of objects quite unknown to the classic Roman. The



Chap.xi. The thyrde boke John

wyth a cauſtyke of capitell, whan the matter is aboute the ſkynne. Than afterwarde lette the place be mundifyed wyth Unguentum egyptiacum, mengled wyth Unguentum apoſtolorum, or wyth oure pouder of mercurye, or wyth a trociſque of minium. And than lette the place be purified, wyth hony of roſes, and wyth a mundificatyue of Smallage, and incarned wyth oure pouder incarnatyue, the deſcryption whereof is after thys ſorte. R. of Aloes Hepatyke. ℥.iii. of myrrhe, of Frankenceuſe, of Sarrocolle. ana. ℥.i. mengle theym. Lette the place be ſealed vp, and cicatriſed wyth oure pouder cicatrizatyue, and wyth water of Alume, and wyth vnguentum of minium, whych bene wrytte in our antidotarye, whereunto reſorte.

Pouder incarnatiue

¶ The. viii. treatiſe ſpeaketh of the apoſtemes of the hyppes, thyghes, legges. And of the Apoſtemes of the lyuer, and ſcrophules and fugilles whych chaunce vnder the arme holes.

¶ The fyrſte chapt. treateth of apoſtemes of the hyppes hote, and colde, ſaniouſe and not ſaniouſe.

Apoſtemes of the flanckes. &c

Of Apoſtemes of theſe partes, ſome are engendred in the outewarde partes as in the ſtones the flanckes, the fundamente, of whyche wee haue ſpoken. Wee wyll here ſpeake of an Apoſteme that is engendred in the inner partes. The curation of thys apoſteme differeth not frõ the cõmune cure of other Apoſtemes, whereof we haue ſpoken, in the former chappters. Wherefore if it be a colde apoſteme, for the reſolution, and mollificatiõ, and other intentions, ye ſhal procede as in the cure of colde apoſtemes. And likewiſe if it be hote & come to maturatiõ, let it be opened, mũdified, incarned, and ſigilled. &c. as is declared in the former chapters.

Neuertheles thys is to be noted, yͭ it requireth a diſcrete chirurgien, whã there is mattyer or corruption in the place or not, bycauſe of the thyckenes of the muſcles, and of the fleſh. Wherfore good William Placentine in his tyme reſiſtynge chirurgiens, that ſaid that thys Apoſteme was not ſanious obtayned greate worſhippe, and profite. For he made inciſion in the preſence of chirurgiens, and found great quantitie of mattier or corruption in the apoſteme. Thus endeth. &c.

¶ The. ii. chapter of hote and cold apoſtemes of yͤ knees, thyghes, and legges.

The Apoſtemes of the thyghes, knees, & legges, haue no differẽce (touchinge the curation) from apoſtemes of the ſhoulders, elbowe, & of the bone of the arme called adiutoriũ. Wherfore for all the intentions of the cure of the ſame, ye ſhall reſorte to the former chapiters. Neuertheles they differre in onẽ thyng, that is that the pacientes muſte not excercise them ſelues in goynge & cõmynge, as much as ſhall be poſſible. Thus. &c.

Apoſtemes of the thyghes knees and legges.

¶ The thyrde chap. of the ſwellynge of the knee.

There

PLATE 7

modern Italian, while still spoken best in the soft Tuscan sound, and is based upon ancestral Latin, differs as widely as Spanish or French from the original tongue I present you a page from Oribasius, which is from the famous press of Aldus, of Venice, printed in 1560, showing the Latin page of the sixteenth century, plate 4, and a section from Fazio's hygiene, printed in Italian, at Naples in 1887, plate 5 The wide departure from the Latin could scarcely be made more plain, and it is quite clear that even the Italian would scarcely find the Latin language easier to him than to the Spaniard, the Portuguese or the French

Indeed, we may easily see that there is a close correspondence between the French of the seventeenth century and the Latin where, as in this page of Lucretius, printed in Paris in 1692, we have side by side the Latin and the French, plate 6 Nor is the divergence of modern French very great from the Latin We may exclude English from consideration on account of its extreme difficulty It is not strange that it should be difficult when we reflect from what varied roots the English language is derived The Teutonic, Gothic, Celtic and French contribute to its common stock, while its scientific language is mainly of Greek and Latin parentage, and this conglomerate, more rich in words than any other, except perhaps the monosyllabic tongues of the Orient, are more varied and flexible than any other But the scientific foreigner can only acquire our language with extreme difficulty, and he rarely if ever learns to speak it without a betraying accent All arguments considered, I have come to the conclusion that the French language is that most easily acquired by other nations, and the one that can be used for the purposes of an international scientific language with least friction

As already mentioned, it is now the language of diplomacy and polite society throughout the world Nearly every medical man who learns a language in addition to his own, learns French This is absolutely true of all Latin nations At the International Medical Congress of Berlin, I never met a physician from Mexico or Central or South America who was unable to speak French, and I attended a dinner at Prof Martin's, where nearly every country was represented, and the language spoken was French, notwithstanding our host was German and we were in the great German capital In Roumania and Turkey the medical publications are largely in French, and in Buenos Ayres and Brazil medical pamphlets are usually published in French even if published in the native Spanish or Portuguese, and in many cases such documents are duplicated

It seems to me that laying aside all questions of sentiment, either of romance or patriotism, and keeping steadily to the utilitarian question confronting us, we must admit that we may meet more people on a common level by the use of the French language in all international gatherings, than by the use of any other known tongue The transition from Latin to French is so easy that almost anybody who has conquered the rudiments of Latin, may acquire a translating knowledge of French in a very short time

I quite agree with Dr Rose in the statement that in learning a language we must learn it by ear as well as by the eye, and instances are numerous where one with good translating knowledge of a language, has no knowledge whatever of its sound For this reason, if there were no other, the study should be carried on conversationally as well as by reading the written or printed word This applies with as much force to French as to any existing language

The changes in the French language in the last three hundred years are much fewer than in the English language of the same period If you examine one of the English black letter scientific books, such for instance as this section from an English translation of John de Vigo, printed in 1550, plate 7, you will doubtless have to look twice to realize that it is English, as it was written, but the French of the same period, while naturally changing somewhat, remains so nearly the same that it may be read without difficulty

I conclude, gentlemen of the ASSOCIATION, not with a certainty that the question is settled, but with the firm conviction that you are increasing the scholar class in our profession and that you will be able to unite on some language which we may all choose as our second language, to be used at our international gatherings to the glory and advancement of medicine throughout the world

LECTURES

OPENING LECTURE OF THE COURSE ON MILITARY HYGIENE

BY MAJOR CHARLES SMART

SURGEON U S A, ARMY MEDICAL SCHOOL WASHINGTON, D C

Hygeia was the Godess of Health, the daughter of Æsculapius Hygiene is the science of Health It was called by Prof Parkes the art of preserving health, but since he wrote the introduction to his classical work hygiene has been developed by study and observation into a science, and its art or the practical application of its laws has recieved the name of sanitation We are here to study the science and its practical applications, not only that we may protect the soldiers of the United States from the attacks of disease, but that we may preserve their physical powers at their maximum of vigor

The duties of an army surgeon are various They require him to be a many-sided specialist When a soldier becomes sick the army medical officer has to treat him as his attending physician, when accidents or injuries occur he has to be prepared for the emergency as operative surgeon, but at all times he has to watch over the health and strength of the command as its sanitary or health officer In this last respect his duties do not differ materially from those of the health commissioner of a municipality The health officer of a city has to guard the community against the introduction of infectious diseases by a system of quarantine or of careful inspection If any infectious disease, such as smallpox, scarlet fever measles, diphtheria, cholera, or yellow fever, should make its appearance in the city, nothwithstanding his precautions, he must endeavor to prevent its spread by isolation, disinfection and other special means, meanwhile determining, if possible, its derivation and the measures to be adopted to prevent the occurrence of other cases from the same source He has likewise to guard the city against any outbreak of disease from local insanitary conditions, or in other words, to see that all nuisances are abated He has to look after the wholesomeness of meat, milk and vegetables, and the condition as to purity or adulteration of various articles of food He has to keep guard over the water supply, whether general from the city reservoir or local from wells or springs, and to provide for the satisfactory removal of offal, garbage, waste water and night soil Lastly he is responsible for the accuracy of the vital statistics of the community To enable him to perform these various duties he has the assistance of a staff of expert employes, including sanitary, police and plumbing inspectors, bacteriologists, analysts and statisticians

The army medical officer has similar responsibilities, but he has no such staff, he must be prepared to undertake by himself any or all of these duties as the occasion may require Hence the necessity on his part for a more intimate knowledge of the methods of practical hygiene than is usually conveyed in the curriculum of a medical college

It is only in recent years that the status of the army medical officer as a health officer has been officially recognized It is true that in the early years of the republic he was charged by the Regulations to do everything in his power to eradicate contagion, but this meant only contagion in the hospitals, the contagion of hospital gangrene and of the deadly typhus fever, and gave him no power over the general well being of the troops The Regulations of 1828 provided that when troops were in quarters the surgeon should from time to time inspect the rooms and kitchens, the quality and preparation of the food, and the location and condition of the vaults, reporting defects and suggesting improvements to the commanding officer, who was thereupon directed to take such action as seemed to him necessary and proper The surgeons did this honestly and faithfully, inspecting and recommending until they became tired of making recommendations that were never carried into effect, for the commanding officers of those days seldom considered it needful or proper to take any action, but instead often regarded the medical officer as officious and meddlesome, and his report and recommendations as reflections on their administration For many years the Regulation was, therefore, a dead letter, but in progress of time the popularization of sanitary science became such that military commanders began to have a better appreciation of sanitary recommendations, and as a result we have now vastly improved conditions and lessened rates of sickness and mortality At the present time most military officers are as interested in the sanitary condition of their men as are the medical officers themselves

I have told you that the duties of the military health officer do not differ materially from those of the civilian officer, they are both based on the same principles It may be well, therefore, to outline briefly some of the salient features in the history of hygiene that you may the better appreciate the value of sanitation in improving the condition of the human race Ordinarily medical men in dealing with medical history drop back to Hippocrates, the Father of Medicine, who lived in the fifth century before Christ, but hygiene was known and hygienic rules followed long before his time Among the Greeks the very name *hygeia* suggests its existence as far back as the mythical time of Homer's Iliad, while about the same time in the wilderness of southern Syria the leader of the Israelites elaborated a system of sanitary rules for the protection of the nation which he had formed out of the Egyptian bondsmen In doing this, however, it is probable that he gathered up into one system of sanitary law all the knowledge of the subject then possessed by the priests and learned men of the Egyptians He insisted on cleanliness, the isolation of the sick and care in the selection of articles of diet, and in carrying into effect these rules, which was scrupulously done by the Jews in after ages, they oftentimes protected themselves from epidemics of disease which scourged their Christian neighbors

It is, however, to Hippocrates that the credit is usually given of having been the first teacher of hygiene He had established a sanitarium and college of medicine at the springs on the Island of Kos in the Aegean Sea, and his name and reputation were known throughout the whole of the civilized world, that is throughout the Grecian peninsula and in the settlements on the shores of the Mediterranean It is related that Pericles sent for him to come and save the city when the plague was devastating Athens and threatening the extinction of the people He went, and found magnificent dwellings and luxurious interiors, but the city as a whole saturated with filth He began his work of sanitation by draining and cleaning up, and endeavored to protect against seizure by keeping large bonfires, to which aromatics had been added, burning in the streets, thus recognizing, not an infection which he was destroying, but an unusual and harmful constitution of the atmosphere which he was endeavoring to alter This epidemic constitution of the atmosphere, in explanation of the existence of epidemic disease, has survived almost to the present day, lingering longest in connection with influenza, but the progress of bacteriology may be said to have now laid it to rest On his return to Kos he wrote his book on "Air, Water and Places," which is regarded as the first work written on the subject of hygiene

Rome received her instruction in medicine from Greek physicans, but she appears to have elaborated her own system of sanitation, for the great sewer of the Tarquins, which to-day helps to carry off the waste water of the city, was built 140 years before Hippocrates was born It opens into the Tiber by an arch twelve feet high, surrounded by three tiers of voussoirs Three hundred years later the Appian Way was commenced, and the first water from a distance was brought into the city by the Censor Appius Claudius Cæcus In another 300 years, or in the time of Augustus, the aqueducts bringing water from the Sabine hills were 270 miles long, 30 miles crossing the Campagna on lofty arches The Campagna at that time was covered with villas and country seats, malaria was unknown, for drainage and cultivation kept it in good sanitary condition Every care was taken of the health of the people and of the sanitation of the imperial city Later, hygiene degenerated into luxury, which has left a record in the ruins of the public baths The colonnade surrounding the Thermæ of Caracallus was a mile long, and enclosed trees, flowers, lawns, and a stadium for the exercise recommended to be taken after the bath, but if one were lazy the halls, theatre, museum, library, etc, within the building afforded other means of enjoyment At the present day the remains of this structure are, after the Colosseum, the grandest ruins in Rome

In progress of time the civilization of the Roman Empire was swept away by the inroads of the northern barbarians Alaric of the Visigoths captured Rome early in the fifth century, and Genseric toward the middle of that century completed its destruction The dark ages descended upon Europe, and nearly a thousand years elapsed before the dawn of our modern civilization began to illumine the mental atmosphere of the Aryan race.

Two diseases which affected humanity from the earliest periods of recorded history had much influence in stimulating a practical interest in preventive medicine. To leprosy we owe our present hospital systems, and to the plague our system of quarantine and maritime sanitation.

Leprosy was common among the Israelites throughout their history. They brought the disease with them from Egypt, and from the Egyptians also Moses no doubt obtained his rules for diagnosis and for the segregation of the lepers without the camp, as given in Chapter xii of Leviticus. General Lew Wallace, in his novel, "Ben Hur," gives a realistic picture of the life of those affected with leprosy at the beginning of the Christian era. Leprosy was introduced into Greece and Rome in the first century by troops returning from Syria, and thence it spread slowly, almost imperceptibly, to the colonies in France, Spain and Britain. A thousand years later it was epidemic in Europe, and continued so for many hundred years; even royalty was not exempt from its infection. Every town of any size had its hospitals for the isolation of the lepers. There were 95 in England and no less than 2,000 in France, and the laws regulating them and their inmates were strictly enforced. These undoubtedly contributed much to the suppression of the disease. A few survivals of its existence continue in Europe, notably in Norway. Its prevalence continues in Asia and many other parts of the world, particularly in the West Indies; in the Hawaiian Islands 2 per cent of the natives are said to be affected.

The nature of the plagues of ancient history is uncertain. Besides that which we now recognize as plague, they probably included all fulminant febrile infections. We do not know the nature of the plague of Athens in the time of Pericles, nor of that which devastated Rome thirty years earlier and which, according to Livy, destroyed most of the slaves, one-half of the citizens, many senators, priests, tribunes, and two successive consuls. Bubonic plague was was described as a foreign disease by the earlier Roman writers. Europe did not become invaded until the reign of Justinian A. D. 542, when it entered Constantinople from Asia Minor. After this there were repeated reintroductions or epidemics developed from sporadic cases. A great wave started at Genoa in 1346, and continued with periodic exacerbations for twenty years, during which 25,000,000 people were destroyed. At this time contagion was noted as a factor in its spread, and Boccacio tells us of the efforts made to preserve Florence by excluding the disease. Sanitary cordons, the equivalent of what in our day we call "shot-gun quarantines," were drawn around healthy places to preserve them, and around infected places to prevent the spread of the pestilence. Venice at this time was the commercial metropolis of the world. Her vessels brought home the products of the East, and occasionally among them cases of the oriental plague. In 1423 she built a lazaretto for infected sailors, but not until 1484 were laws enacted for the detention of vessels from infected ports prior to permitting the admission of the crew, passengers or cargo. The city of London suffered, as did all the other European cities. Sporadic cases were noted every year, and occasionally the disease spread with epidemic violence. In 1665 the city had been comparatively exempt for seventeen years; but in the summer of this year 70,000 persons died out of a population of less than half a million, two-thirds of whom had fled into the country. The great fire occurred next year, and the subsequent freedom from plague was attributed by many to this purification by fire and the subsequent rebuilding of the city on better sanitary plans; but about the same time the disease began to subside all over Europe. Continental cities ascribed their protection to strict quarantine, but England did not institute quarantine until 1720, when a deadly epidemic in Marseilles threatened the whole of Europe. The progress of civilization, of which sanitation is a part, has banished plague, and it is now found only in the country south of the Caspian Sea and in certain of the seaports in China. It ravaged Canton and Hong Kong in 1894.

The discovery of the protective value of vaccination was the first grand step made by preventive medicine after the modern revival of learning. On May 14, 1796, Dr. Edward Jenner of Berkley, England, vaccinated a boy from the sore on a milkmaid's finger, and on July 1, following inoculated him with smallpox. The protective influence proved by this experiment took the mortal sting from a disease which for ages had more than decimated the human race. It has been estimated that prior to this discovery one-sixth of those born fell victims to smallpox, and of those who survived many were deaf, blind and disfigured. The smallpox pitted face, so common in the early days of this century, is now a rarity among civilized nations.

The study of typhus fever in prisons, ships, camps, and the crowded slums of large cities, demonstrated the existence of a contagion or pathogenic influence which appeared to be called into being under conditions of over-crowding and insufficiency of fresh air, and led to an appreciation of the value of air space and ventilation as sanitary factors in dwellings. The advantages derived from the practical application of this knowledge were the suppression of typhus fever and hospital gangrene, and the lessened prevalence of consumption and of those cachectic conditions that originate in ochlesis or crowd poisoning.

Its further study, leading to the distinction between typhoid and typhus fevers, had also important sanitary bearings, for it ultimately showed that the germ of the former disease was to be found in the excreta. For a time exhalations from these were regarded as containing the infective material. The sewers of a city containing typhoid fever patients were, in the language of Dr. William Budd, "a continuation of the diseased intestines." Sewer air had therefore, to be kept from our houses, and to this effort to protect us from typhoid exhalations, we are indebted for many improvements in sewerage systems and house plumbing. Later when the propagation of the disease by water was discovered, the attention of practical sanitarians became directed to the protection and purification of water supplies, an agitation which is still in progress.

I have said that the plague gave us our quarantines for protection against exotic diseases. It is, however, to cholera and yellow fever that we owe the improved quarantine methods of the present day. Cholera made its first progress over Europe in 1830; and in its periodic visitations since that time it has always come from India, and generally by way of the Red Sea The annual pilgrimage to Mecca brought cholera as well as pilgrims to the Holy City of the Mohammedans, and pilgrims from Europe carried the infection with them on their homeward journey International conferences were called at various times to consider the best system of protection The most important of these was that of Constantinople in 1866, which established a quarantine under international auspices in the Red Sea to intercept infected vessels and prevent Mecca from becoming a great distributing center This did much to restrain the advance of the disease and to relieve the local quarantines in the the Mediterranean Later conferences, as at Vienna in 1874 and at Rome in 1885, did much to lessen the cruelties of a prolonged quarantine by recognizing the English view—that importation of the germ was of less material consequence than local filth and insanitary conditions in the invaded seaport Local sanitation then became the order of the day, with medical inspection of incoming vessels to determine the presence or absence of disease, giving free pratique if no case had occurred on the ship and if seven days had elapsed since leaving the port of departure, but if the ship was infected provision was made for the removal of her sick, the retention under observation of those who apparently were well, and the disinfection of the vessel and her cargo

Yellow fever gave us a similar quarantine or sanitary service in the United States The belief that yellow fever was indigenous in this country rendered our quarantines valueless for many years Since the War of the Rebellion, however, the disease has been regarded as an exotic, and since the widespread epidemic of 1878–79 it has been excluded from the country by an inspection service to determine the condition of the vessel, the detention of infected persons, and the disinfection of infected ships

The registration of vital statistics and the institution of boards of health were two most important agencies in the modern progress of practical hygiene The record of births, marriages and deaths was made at first for legal purposes only It was not until 1839, when Dr William Farr prepared the first annual report of the Registrar General of England, that the value of vital statistics in directing the work of sanitation became demonstrated The mortality returns were the most important in this respect They showed the excessive number of deaths among children under five years of age, the high death rate in cities as compared with the rural districts, and in certain parts of a city as compared with certain other parts of it, the high death rate among persons engaged in certain trades, and the high rates occasioned at times by certain diseases All these facts led to observation and study for their explanation, and these again suggested hygienic measures to remedy the insanitary conditions that were discovered England has the most efficient system of registration The local registrars report weekly to the headquarters in London, and from the office of the Registrar General are issued weekly, monthly, quarterly and annual reports The Registrars General in Edinburgh and Dublin publish similar reports for Scotland and Ireland respectively In the United States many cities and a few of the States have excellent systems, but taken as a whole this country is far behind in the registration of vital statistics Not so, however, the U S Army, for the Army medical officer reports all cases of sickness as well as deaths, and this it is which gives so much value to the statistical reports of the Surgeon General An excess of sickness over the average of the Army at any one post can be detected immediately, and the character of the reported cases generally gives some indication of the nature of the necessary preventive measures

Boards of health, or local sanitary authorities, were a result of the inquiry into the causes of excessive death rates as developed by the registration returns Their duty was to lessen such rates by preventing or removing the insanitary conditions that gave rise to disease or promoted its spread In this country boards were first appointed in our large and growing cities Much good was accomplished by them within their jurisdiction, but it speedily became evident that for efficient work there must be such a cooperation among the local officials as could only be effected by the intervention of the State After a time State boards of health began to be organized by various legislatures, and it is to be observed that much of this work of organization was carried out by medical men who had served during the War of the Rebellion Their duties and experience as Army medical officers had impressed upon them the value of preventive measures and each, having influence in his own State, became an important agent in promoting the progress of public sanitation Derby in Massachusetts, Rauch in Illinois, Hewett in Minnesota, Baker in Michigan, and many other pioneers of State medicine in this country were volunteer medical officers during the war

Many of the annual reports of municipal boards contain valuable papers in the form of reports of committees on the local water supply, drainage, sewerage, etc , and on the measures adopted for the suppression of epidemic diseases The reports of the State boards also are mines of sanitary information

But you will readily understand that just as there are subjects of sanitary import that exceed the jurisdiction of a municipality and require the intervention of State authority, so there are subjects so extensive as to reach beyond the lines of a particular State, although of the greatest importance to the well being of the people of that State One which is calling for federal legislation at the present time is the prevention of the pollution of rivers and other natural sources of water supply, the people of one State who drink the water having no authority over the sewage disposal of cities in an adjoining State by which it is contaminated To preserve the people of the whole country from insanitary conditions a perfect cooperation is needful among State and local authorities A good understanding prevails among medical and sanitary authorities, but these are too often powerless to accomplish the end in view Municipal authorities and State legislation view the sanitary proposition from the financial standpoint, and they are not likely to authorize the expenditure of funds for a special and costly method of sewage disposal that the water supply of some other State or city may be protected

The protection of the coast line against the importation of cholera, yellow fever, smallpox, etc , is also a subject on which there must be either a perfect cooperation among local authorities or a federal supervision, for an efficient quarantine at one seaport is of no value to a country if the disease effects a landing through the inefficiency of the service at another port There are also many questions concerning protection from indigenous diseases, such as consumption and typhoid fever, which are of interest to all the States, and which could be studied to better advantage under national auspices than by the individual and uncoordinated efforts of the several States

For these reasons most of the medical and sanitary men of this country are anxious to see established a National Board of Health In this respect the United States is behind the age The English have a central health authority called the Local Government Board, which comes, when necessary, to the assistance of the local health authorities Germany has its Imperial Board, which has become famous by the work of Dr Robert Koch in its laboratory Our Mexican neighbors have a Superior Board of Health for coordinating the work of the State boards, and even Japan, the latest national adjunct to modern civilization, has a Central Board of Health

In 1871 a number of sanitarians met for the purpose of organizing an American Public Health Association One of the objects of this Association was to secure legislation on behalf of the public welfare, and particularly to obtain federal recognition of the importance of the subject by the establishment of a National Board of Health But its efforts in this direction were neutralized by an argument based on the unconstitutionality of such a board In the cession of certain of their powers by the States to the Federel Government for the general protection, the police powers of the States were not included The right of the local authorities to be supreme in such matters prevented action by the general Government A few years afterward, however, the disastrous epidemic of yellow fever which devastated the South in 1878, so overcame the State's rights doctrine in connection with health matters that the strongest supporters of a National Board of Health were the members of Congress from the Southern States A bill establishing a board was passed in 1879, and this Board did excellent service in protecting the country from imported disease, and in promoting sanitary work in the various States Under the impetus given to sanitation during the few years of its existence boards of health were organized in most of the States, and these latter fostered the organization of local boards and kept up close official relations with them, so that nothing of a threatening character could occur in any part of the State without an immediate reference to the State Board for advice or assistance

The National Board was ultimately destroyed by the continued operation of the influences which opposed its organization The Marine Hospital Service now conducts the duties of maritime quarantine on the lines established by the National Board of Health, but this service does not fulfil the purposes of a federal board in questions of internal sanitation Medical men and sanitarians are therefore as earnest at the present time as they were in 1871 in their efforts to secure national health legislation, and as the President in his message to Congress last year indicated its necessity, there seems some prospect that this country may soon have a central or federal sanitary bureau or even a Department of Health, as urged by the American Medical Association

I have given you this general sketch of the progress of hygiene and sanitation that you may be better able to appreciate the relations of military to public hygiene, for the Army medical officer in time of peace has usually a civilian settlement attached to his station for which he must act as health officer, and in time of war the sanitary interests of large sections of the country may devolve upon him

At our next meeting I shall bring you into more immediate contact with the military branch of the general subject of hygiene and sanitation

---

REMARKS ON CLINICAL CASES

I PHLEBITIS AND PERIOSTITIS FOLLOWING TYPHOID FEVER, II ACUTE BRIGHT'S DISEASE, III POST-HEMIPLEGIC TUMOR

Lecture delivered at the Pennsylvania Hospital, Nov 9, 1895, Reported stenographically for the Journal.

BY J M DaCOSTA M D, LL D

PHILADELPHIA

EMERITUS PROFESSOR OF PRACTICE AND THEORY OF MEDICINE IN THE JEFFERSON MEDICAL COLLEGE

Gentlemen —You will be interested, I think, in seeing the progress of some of the cases that were before you at our last clinic, a series of cases illustrating sequelæ, of unusual occurrence in our day, of typhoid fever This young man was the case of femoral phlebitis, phlegmatia dolens it was formerly called, or milk leg, which an accurate pathology has taught us to now regard as phlebitis You will recall that I directed your attention to the course which this ran, how it began in the right leg, how that leg became tense, painful and swollen, how the swelling gradually subsided, except along the course of the femoral vein Now, it had hardly subsided before we began to notice swelling and tenderness in the calf of the other leg We next observed some swelling over the glands in the groin and tenderness over the left femoral vein, the most marked features, however, being the tenderness in the muscles of the calf Recognizing this as a phlebitis in this limb, we began the treatment as before, by elevating the limb, making applications of witch-hazel distillate, and administering the tincture of the chlorid of iron, internally I am happy to say that under this treatment, the inflammatory condition has subsided, the swelling and pain, and the tenderness in the calf, which at the beginning were such marked symptoms, have disappeared There is now no longer any tenderness along the femoral vein and the swelling of the glands has also gone In fact, the man is perfectly well except that he must be cautioned against standing much upon this leg for the present, or using it much in walking, for a certain amount of edema will result from using the limb too soon

The interesting fact in this case was the early and valuable diagnostic sign that we obtained from the tenderness in the calf, which indeed was the first manifestation of the phlebitic process The patient is now convalescent, but he may continue the tincture of iron three times a day, with a good diet

Having disposed of that case, we can briefly dispose of the case of periostitis following typhoid fever

Here, gentlemen, is the case, which I told you was regarded as one of periostitis of the tibia following typhoid fever There was much swelling over the front of the tibia extending along this bone, but tenderness upon pressure and pain were the most marked features There was slight elevation of the bodily temperature, which no longer is present This morning there is no tenderness, and the swelling of the covering of the bone has subsided, although the patient still complains of some soreness of the skin where the blister was applied He was, indeed, treated with blisters over the site of tenderness and he was kept at rest in bed, with the foot slightly elevated He is well, and nothing more need be done for him

ACUTE BRIGHT'S DISEASE OF THE KIDNEYS

The next case is one of acute nephritis, one of a kind we see frequently in practice

The patient is a sailor, 21 years of age, who has been much exposed at sea He was brought here with the statement that he had had some form of obscure fever at sea, of which the exact history can not be now ascertained Following this fever, he had an eruption of some character upon his legs and face We also know nothing about this eruption, although from his occupation we may have our surmises as to its specific character, yet we can know nothing about it The eruption upon the legs may have been caused by some local application of the nature of which we are not informed, it may have been some preparation of coal oil He says that he did use some application and that it was followed by this eruption besides a good deal of inflammation There was desquamation after he came into the hospital This was the only history we could obtain of the case

When he was admitted his temperature was 102° in the evening and a slight decline took place next morning The fever temperature gradually subsided, and this morning it is 100 6 ° When he came in, his face was very much swollen As you perceive, it is still somewhat swollen, but nothing like it was on admission His legs were swollen also, they are less swollen now You see this curious eruption upon the legs When my attention was first called to it, I was asked if it was smallpox in its declining stage, but it has none of the characteristics of smallpox I believe that it was due to some irritant, like coal oil, some application which was made while at sea Of course, as already hinted, as he is a sailor we might assume that it is due to syphilis, but as it is limited to the legs, this is against that view Moreover, he positively denies anything of the kind, or that infection exists Upon thinking over the case, it occurred to me that it possibly might be due to some strange blood eruption, like the eruption of purpura, but the fact that it is found only on one part of the body, the legs, and that it is papular instead of being petechial, decided against this also I then concluded that while the exciting cause was an irritating application, the subsequent course of the eruption was due to the course of the disease What disease? Well, from the general appearance of the man, his puffy face and evident anemia, I concluded that it was a case of Bright's disease The urinary examination confirmed this view Here is the statement Urine reddish, with a flocculent sediment, acid in reaction, specific gravity 1022, albumin present in large amount, no sugar Some finely granular and epithelial casts and much debris, urates, etc The daily quantity when he came in was twenty ounces, therefore scanty Yesterday he passed forty seven ounces

With this large amount of albumin and scanty urine, with swollen face and fever, there was no doubt that we had here a case of acute nephritis, one of the forms of Bright's disease If you ask, What did it follow? we can not here be certain, we simply take it as a case of acute Bright's disease, with inflammation in the tubular portion of the kidney and exudation and swelling interfering to a considerable extent with the function of the kidneys and causing scanty albuminous urine This condition may follow cold and exposure, it may follow acute rheumatism And especially is it seen in persons who are rheumatic and are then exposed to cold and dampness It frequently follows scarlet fever, and the thought may occur to you that this is a case of acute nephritis following scarlet fever It is true he had fever on board ship, and an eruption, the character of which we do not know, nor can we ascertain the nature of the feverish attack Gentlemen, we will have to leave this as a matter of doubt, but I rather incline to think that it was not scarlet fever The man himself states that he had no fever, but we know he must have had some because he came in with a fever But that is a matter of no great significance, the main point is the condition in which we find him at present Let us inquire into the future course of the disease and whether it will recur We will also take up the question of *treatment*

Acute Bright's disease is an inflammation of the cortical portion of the kidneys, they become swollen up, congestion and exudation occurs, serum and blood corpuscles enter the tubules and appear in the urine Epithelial, hyaline and granular casts and blood elements are detected with the microscope Under favorable circumstances and with good management, these all disappear Nine out of ten cases recover perfectly, the tenth case may not recover, that is to say, the condition may pass into a chronic nephritis and the large white kidney may result Recovery is therefore the rule in acute nephritis *under treatment*, but this presupposes care and treatment and does not take into account a possible occurrence—there is always a danger of these inflamed kidneys suspending action and producing uremia and convulsions Therefore, while the prognosis is, on the whole, favorable, it is so only under proper treatment If this can be obtained the prospects are that the albumin will slowly disappear from the urine and the kidneys slowly resume their functions But these patients, in the future, after fresh exposure, will be likely to show a small amount of albumin in the urine So much for the prognosis The diagnosis is an easy one The swelling of the face and limbs, the presence of albumin in the urine, the small quantity of urine, the presence of tube casts—all these make up a clear and distinct diagnosis of acute nephritis In what stage of the disease was this man when he reached us? Was he still in the acute stage, or had it passed? It had passed, the disease had reached its height before he came in Why do I say this? Because there was no blood in the urine During the first week or longer there is blood in the urine and blood casts, casts with blood cells on them, with very many leucocytes You recall the fact that this man's urine had no blood and no mention is made of leucocytes We must conclude then that the most acute stage had passed before he came into the hospital

Now as regards the treatment The most important points are to act upon the skin and the bowels and to keep the kidneys flushed, by diaphoretics, cathartics and diuretics You must use derivative treatment, while putting the patient upon the blandest diet, chiefly fluid, with a view, as I have just said, to keeping the kidneys flushed How is this to be effected? The best remedy in the treatment of acute nephritis with which I am acquainted is digitalis Indeed, it is an interesting fact in medical history that digitalis had a reputation in connection with disease of the kidney long before it had gained its reputation in disease of the heart In this case it is given as a diuretic, and I shall frequently have occasion to point out its value in the treatment of similar cases The preparation I prefer is the infusion, giving half an ounce four times a day Under this treatment the urine has increased from 20 to 47 ounces in the case before you In addition, so that nothing in the diet should irritate those inflamed kidneys, we placed the patient upon a milk diet, he has had an absolute milk diet and nothing else since his admission We usually allow in addition a certain amount of fluids, such as weak tea, or any natural diuretic water If you are not sure of the quality of the water, use distilled water, as the most important element in these waters is the water itself In this way you keep the kidneys flushed out by using water As long as the patient is passing 47 ounces daily, I am satisfied In addition we purged this man with one or two drachms of Rochelle salts, given each morning Then we also acted upon his skin, and there is nothing better for this than a vapor bath This can be easily arranged by means of a few hot bricks, but where it can not be carried out, you can resort to some diuretic Jaborandi or its alkaloid pilocarpin may be used, the latter in doses of one-sixteenth of a grain, given three or four times daily, would be very serviceable We have not used it here, as we used the baths instead

Under this treatment, there is no doubt of this man's ultimate recovery, provided he escapes uremic accidents, and I hope to be to be able to show him to you before he leaves the hospital without a trace of albumin in the urine I must speak of one more feature in these cases which I omitted, that is the fever The degree of the fever is not high, the temperature going as in this case, to 102° or 102 5°, but not much higher than this

POST HEMIPLEGIC TREMOR

Here is a man of whom as yet I know very little, as he has been in the hospital only a very short time His name is J S, he is 58 years of age, colored, a clergyman by profession The notes taken upon admission state that his family history shows no hereditary taint He has used tobacco in moderation, but no alcohol for many years He has been ill for nearly two years He is subject to attacks of cardiac asthma, or dyspnea, with pain around the region of the heart He has had a few attacks of epistaxis and also has had attacks of hemoptysis He says that suddenly, while preaching one day, he found that he could not raise his left arm or move his left leg, nor could he close his left eyelid Note this curious fact—all this happened while he was preaching His speech was not affected nor did he lose consciousness, in fact he hardly noticed that anything had happened to him He was admitted into the hospital about eighteen months after this occurred During these eighteen months his general health was fair and he regained some power in the left hand and in the leg also, but was able to walk only a short distance Just before admission he had another slight attack He did not notice this himself, but his daughter says that he became weak and his mind was distinctly clouded It is not known whether or not there was any additional loss of power

Since his admission, we have learned that he had lost flesh during the past year, that his mental condition had become enfeebled, that he has had attacks of giddiness, and that he is subject to slight headache, but this he has not complained of since he came into the hospital Headache has not been a prominent feature His temperature has been running about normal, with slight variations His respirations are 20 to 27 to the minute His pulse 86 to 90, somewhat irregular, every now and then intermitting a beat The radial artery is resistant to the touch When I listen to his heart, I find a distinct, harsh, mitral, systolic murmur, and an accentuated pulmonic second sound The apex impulse is diffused and only of moderate force There is some hyper trophy, but only of moderate extent That is with regard to the heart The urine is passed involuntarily and it is impossible to get at the exact amount, as he generally passes it in bed It contains a trace of albumin, of specific gravity 1018 and neutral in reaction The bowels are irregular The tongue is coated, flabby, and deviates a little to the left when protruded He has some control over the left arm, but note the tremor as he raises the hand He says it has trembled a great deal My impression is that there is a very slight tremor when the arm is at rest and a very distinct tremor when he attempts to move the hand The legs do not tremble This tremor is associated with loss of power to some extent in the left hand and arm Sensation is diminished on the left side You observe that these pin points on the fingers, separated a considerable distance, are felt as one Sensation is therefore diminished but not abolished on the left side

Now, gentlemen, what is the matter with this man? He can walk, but has loss of power in the left leg and loss of power in the left arm and hand There is stiffness in the muscles of the left arm, and some wasting We have tested the electrical condition of the muscles and find that there is beginning reaction of degeneration, though not marked There is diminished sensation and power, but not complete paralysis There is also tremor in the left hand What has happened here? What was the original disease and what has been its course, and what is occurring now? The original condition was one of cerebral embolism It was a clear case The loss of power came on suddenly in the arm and leg, occurring—and I lay great stress upon this—without loss of consciousness He went on talking, with complete loss of power on the left side of his body, showing that you may have hemiplegia without loss of consciousness When this occurs, in nine cases out of ten it is a case of cerebral hemorrhage Here you have an additional reason for this diagnosis in the disease of the heart A small plug has been washed from the mitral valves and carried into the smaller vessels of the brain and shut off the blood supply to the motor centers of the left arm and leg

What has happened since the embolism occurred? What often happens in these cases of cerebral embolism—the mental condition has been impaired Following loss of nutrition in the cortical centers and impairment of function, degenerative changes in this area have taken place While, as so often happens, there has been some recovery of power, the power has not been entirely restored But this loss of power is not so much what I wished to show you, as the tremor of the left hand, a spasmodic trembling often associated with disturbance of functions Now, gentlemen, this is a condition much more common in cases following embolism than in paralysis from rupture of vessels, and it indicates, in nine cases out of ten, a clot in the vessels rather than an effusion of blood

You ask the cause of the tremor? Why should the man have a trembling hand, a tremor that has been termed post hemiplegic chorea? It is extremely difficult to give any definite information upon this point The tremor with the spasm that may complicate it is due to a deficient blood supply in the motor centers in the brain, either of the cortex or elsewhere Disturbance of nutrition is followed by disturbance of function, and under certain circumstances by structural change and degeneration While this explanation is not easily proved, yet we know that a certain amount of blood supply is necessary to maintain a condition of healthy nutrition, without it, an altered nutrition with tremor and spasm occurs Now, you may ask where this lesion was located Considering the hemiplegic and hemi anesthesia on the left side, it affected the right side of the brain and points to the internal capsule involving the posterior thoroid

Let me briefly speak of the treatment of this case The patient is to be kept as well nourished as possible Keep the bowels acting and watch the kidneys In the early stage of the disease possibly iodid of potassium may do good, but where it has existed as long as it has here, we can not expect very much from it We will give him the syrup of hypophosphites He shall have gentle massage and good diet We will caution against exertion and advise rest Otherwise no special treatment is needed as there is no way of repairing these damaged valves which involve, by their ultimate effects, far more serious consequences than their original attack

ORIGINAL ARTICLES

NOTES ON RETENTION OF URINE FROM URETHRAL STRICTURE

Read before the third district branch of the New York State Medical Association

BY JOHN W S GOULEY, M D
SURGEON TO BELLEVUE HOSPITAL NEW YORK.

The purpose of these notes is to recall attention to some of the ready and simple methods of relieving sufferers from the distress caused by retention of urine due to urethral stricture This kind of urinary retention is seldom sudden, it is ordinarily preceded by difficult urination, whose increase—from month to month, from week to week, from day to day—is proportionate to the diminution of the urethral caliber at the diseased point, and also to the degree of muscular spasm of that part of the canal For several weeks prior to complete retention, although urination be very frequent, the bladder is not emptied, this constitutes incomplete retention of urine which, from its stagnate state, soon gives rise to cystitis At length the urine ceases to flow, there is then complete retention This urine, accumulating for thirty-six or forty eight hours, begins to slobber involuntarily, when the complete relapses into incomplete retention

The laity often regard involuntary escape of urine as cause rather than effect, and endeavor to repress the "undue flow" by sundry processes which, fortunately, prove ineffectual Meanwhile the vesical distension increases, and unless the patient invokes a physician's assistance without further delay, the urethra is likely to burst behind the stricture and give issue to the urine, which infiltrates and destroys the connective tissue of the perineum and scrotum In rarer instances of inordinate vesical distension, a fall, a sudden movement of the body, or a violent struggle during anesthesia has been known to cause rupture of the bladder

Long standing incomplete retention of urine with spasm of the bladder is much more serious than the retention which becomes complete in the course of a few weeks for, in the first-named condition, the upper urinary organs are often irreparably damaged and the prognosis is generally unfavorable It is before the advent of these untoward effects that the greatest good is to be accomplished Therefore, experienced physicians recommend the early treatment of stricture as preventive of retention of urine and its ill consequences, but their instructions are seldom followed, and the responsibility rests with all unruly patients who are too apt to seek advice at the last moment, when the bladder is distended to its utmost degree and the suffering is more than can be longer endured, even by the most stolid of men, after divers nostrums have been tried and found wanting in efficacy

It is too common in such cases to resort to cutting operations, which are indicated only after failure of careful catheterism with filiform bougies, or after repeated supra pubic capillary puncture of the bladder and aspiration of the urine In ordinary cases it is possible to give prompt relief by making some preliminary dilatation of the stricture, beginning with a No 1 soft, olive pointed bougie, and continuing the dilating process by passing successively Nos 2, 4, 6 and 8, after which it will be easy to use a No 7 curved web catheter that serves to allow the urine to flow slowly until about two thirds of the amount contained in the bladder shall have escaped The catheter is then plugged at its free extremity, is fastened in position, but is not retained more than thirty six hours, during which time some urine is drawn off every three hours, and the bladder finally emptied a few moments before the instrument is withdrawn After this the stricture is gradually dilated by using bougies of increasing size every third or fourth day until the normal caliber and suppleness of the urethra is restored Without preliminary dilatation by means of small bougies, it is usually difficult and often impossible to introduce a necessarily small web-catheter by reason of its undue flexibility as soon as it is warmed in the uretera The insertion of a metallic stylet in a small web-catheter is not prudent on account of the possibility to perforate the instrument and the urethra, even when the manipulations are carefully and gently conducted

Any stricture amenable to the method of treatment above described may be regarded as an easy case The physician is, however, liable to be called to minister to cases that are not manageable with regulation bougies Like cases have been related with the paradoxical title "The way to pass impassable strictures," or "How to pass a bougie when it can not be passed" These surgical bulls have come forth from time to time during the past three decades The meaning sought to be conveyed seems to be, in the first case—how to pass strictures that are impassable by ordinary instruments, and in the second case—the kind of bougie to use when the common sort fails. These ideas could have been more briefly expressed by—catheterism in difficult cases.

The difficult cases are those of very narrow, eccentric, tortuous, dense and resilicut strictures, which are accompanied by inordinate spasm of the muscular layers and are seated in the perineal region of the urethra. A second narrowing in the penile region is generally a troublesome complication which often necessitates internal urethrotomy.

A debauch, in wine or venery, is commonly the excitant of complete retention of urine. In such a case the urethral mucous membrane is likely to be swollen and sensitive, and to bleed freely as soon as a bougie is passed. As a general rule, when catheterism is not deemed expedient, the bladder is punctured above the pubes with a hollow needle, through which the urine is aspirated and, if necessary, the operation is repeated until suitable instruments can be used to treat the stricture.

One of the simple and ready methods of entering a narrow stricture, whose lumen is eccentric, is by means of a filiform probe-pointed whalebone bougie, elbowed at its extremity. This instrument is used as an explorer of the narrowed canal and is quickly passed through the stricture in nine out of ten difficult cases, and serves as a conductor for a No. 1 or a No. 2 conical curved steel staff, grooved along its convexity, and having a canal or tunnel two or three millimeters in length, beginning at the blunt point of the instrument and ending in its groove. Through this canal is threaded the bougie, which guides the staff into the stricture, dilating it sufficiently to permit the introduction of a larger tunneled sound, then a third, fourth, fifth, and so on, until divulsion occurs. After this a tunneled catheter is substituted and enough urine is drawn off to relieve the distress caused by distension. The bladder is not completely emptied until the second day. The object of delaying to empty the bladder is to guard against vesical hemorrhage, which is so likely to occur after the sudden withdrawal of all the urine in cases of long-standing distension of the viscus, particularly in elderly men.

It sometimes happens that stricture is so dense that it can not be dilated by the tunneled sound beyond No. 2 or 3. In that case a tunneled catheter No. 2 or 3 is substituted, and through this instrument the urine may be aspirated if necessary. Then a small web-catheter is passed and fastened in position for forty-eight hours, during which time the urine is allowed to trickle out, partly through and partly beside the instrument. On the third day it is generally possible to carry on dilatation with less difficulty and, if needed, the process of continuous dilatation may be repeated until the stricture shall admit a bougie of the size of the normal caliber of the urethra. When, however, a stricture seated in the perineal region can not be entered with any kind of bougies, after repeated trials, it is proper to resort to its external division, with the double object of curing it and of relieving the distended bladder.

For some years past there has been a pernicious fashion of dilating the strictured urethra to an excessive extent and of using the dilators with undue frequency. In the many cases so treated the consequence has been a total loss of the urethral suppleness due to sub-acute urethritis, with extensive infiltration of round cells and their subsequent transformation into scar tissue, so that the canal, although greatly increased in caliber, is in a state of permanent contracture.

Men of dissolute habits, like the cases presently to be stated, seldom return for radical treatment until they are again suffering from retention of urine. Narrow resilient strictures are not permanently cured by any method of treatment whatsoever, unless the treatment is followed by the persistent use of dilating instruments, once every week or ten days, for at least three years. Some patients need the use of such instruments for many years, if not for life,

The following recent cases may serve to illustrate the efficiency of tunneled sounds and catheters in difficult cases of urethral strictures with complete retention of urine.

W. L. S., 28 years of age, was admitted to Bellevue Hospital on the 8th of April, 1895, suffering much pain from retention of urine, which had become complete thirty-six hours before. He had had three attacks of urethritis, the first, twelve years, the second three years, and third, eight months, before admission to the hospital. The first attack lasted three months, the second, four months, and the third merged into a gleet which existed at the time of his final retention of urine. During the eight months prior to admission, he had repeatedly had complete retention of urine after great abuse of ardent spirits, but was each time spontaneously relieved, except after the last debauch, which began early in April, 1895, when, on the morning of the 7th of that month, the retention persisted, but he did not apply for medical aid until the following morning, and the physician employed undue force in using the catheter, with the only result of drawing blood instead of urine. With his bladder distended to the level of the umbilicus, the patient was conveyed to the hospital on the afternoon of the 8th of April. Exploration of the urethra revealed a narrow stricture in the region of the bulb, and a false passage anterior to the stricture. The urethra having been filled with oil, an elbowed filiform whalebone bougie was passed through the stricture and, reaching the bladder, was used as a conductor for Nos. 4, 6, and 8 conical tunneled sounds with which the canal was rapidly dilated, when tunneled catheters Nos. 7 and 10 were introduced, and eighteen ounces of urine drawn. The patient was then sent to bed after he had taken ten grains of quinine. No anesthetic agent had been administered. Three-quarters of an hour afterward he passed spontaneously five ounces of urine without, however, emptying his bladder. In two days the stricture was dilated to No. 12 (English gauge), on the fourth day, to No. 13, and on the eight day to No. 14 which has since been introduced every fourth day. The patient has experienced no untoward effect and has been able to urinate at ordinary intervals, in a large stream, and to empty his bladder. It is scarcely necessary to say that antiseptic precautions were taken in the treatment of this, as well as in the many other cases of urethral strictures received in the hospital.

E. T., 50 years of age, was admitted to Bellvue Hospital, on April 22, 1895, in a profound state of alcoholic intoxication, suffering from complete retention of urine of forty-eight hours standing. His bladder was distended beyond the umbilicus although urine had been slobbering out for twelve hours. He was an habitual excessive drinker and his final debauch had lasted three days He had had three attacks of urethritis in the course of fifteen years, and had suffered retention of urine three times during the twelve months prior to his admission Once the bladder was relieved of its burden of urine by supra pubic capillary puncture and aspiration There were two dense, narrow strictures, one in the penile, one in the perineal region of the urethra Very soon after admission he was successfully catheterized with a filiform whalebone bougie and tunneled instruments, beginning with No 2, and carrying the dilatation to No 6, when twenty eight ounces of clear urine flowed through the catheter, this being about two-thirds of his bladder contents An olivary bougie No 5 was then passed and retained in position twenty-four hours, the urine oozing beside the bougie after a few hours The usual dose of two grains of quinin was administered Dilatation of the strictures was continued every second day, and at the fourth and fifth sittings No 8 was easily introduced In the meantime the patient urinated in a good stream at regular intervals Dilating instruments were used every fourth day until No 13 could be easily passed The patient was advised to continue this treatment indefinitely, and was discharged at his own request on the 27th of May

The writer has employed this method of treatment, in upward of five hundred difficult cases of urethral stricture, with a degree of success that warrants an earnest recommendation of its more general use In the great majority of these cases *no anesthetic agent* was administered, because the operation is not very painful, because it is of short duration, because of the danger of vesical rupture incurred during the struggles of the semi conscious patient in the second stage of anesthesia, and because of the ill effects of some anesthetics—particularly ether—upon the kidneys The mortality has not exceeded three per centum and has been due mainly to advanced disease of the bladder, ureters, and kidneys

SUSPENSION OF THE UTERUS

THE OPERATIVE TREATMENT OF RETROFLEXION BASED ON A CONSIDERATION OF 200 CASES

BY HOWARD A KELLY, M D

BALTIMORE MD

At the meeting of the AMERICAN MEDICAL ASSOCIATION in Baltimore in May, 1895, I made an address before the Obstetrical and Gynecological Section on the subject of the "Operative Treatment of Retroflexion," taking as a basis of my remarks the 170 cases upon which I had operated since coming to Baltimore six years ago Since May I have added thirty more cases, bringing the total up to exactly 200 All but a few of these cases were operated upon in the Johns Hopkins Hospital, the others were patients in my private sanatarium

The mortality in the 200 cases has been zero, and there has not been a case of serious illness following the operation There has been one recurrence of the retroposition, making the failures one half of one per cent In about 5 per cent of the cases stitch-hole abscesses and separation of the lower angle of the incision occurred, this accident very rarely happens now with my present technique in closing the abdominal incision

The suspensory operation was abandoned in one case recently because the enlarged uterus was so friable that the stitches cut out as soon as they were tied

In all cases where the vaginal outlet was relaxed it was repaired at the same time the uterus was suspended, when there is both retroflexion and relaxation of the vaginal outlet, if I can do only one operation, I prefer to lift up the outlet under the pubic arch It is well known that I have always been an earnest advocate of the direct method of treating retroflexion by a small abdominal incision, bringing the uterus into anteposition and holding it there by two stitches through the anterior abdominal wall and the posterior surface of the fundus I am influenced by four principal reasons in continuing this method of treatment, which I originated nine years ago, these are

a A natural tendency to continue an investigation in the line already opened up (see *American Journal of Obstetrics*, January, 1887)

b The advantages of a direct inspection of the ovaries and tubes, as shown by the cases of inflammatory adhesions found at the operation, where it was not known that any had existed In one case I was fortunate enough to find a little papilloma, not as big as the end of my finger, starting out of the ovary When the uterus is adherent no other method can be so good, as this is the most direct way of dealing with the adhesions

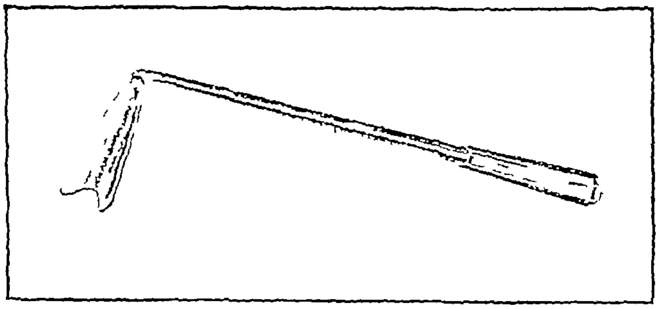

FIG 1—Elevator which serves to hold uterus up while first stitch is being passed

c The mechanical advantages of my suspensory operation acting directly on the posterior surface of the retroflexed fundus, are better than the same organ held forward by pulling on the round ligaments on both sides

d Probably the best reason of all is the remarkable statistics of my 200 cases without a single death, and with but one recurrence of the displacement in a patient in whom a tube and an ovary were removed at the same time

With this introductory statement I present my address substantially as given at the Music Hall last May, with the analysis of the first 170 cases The last thirty are more recent and may, therefore, be left out without disadvantage

I hope the illustrations which accompany my paper will help make clear some points which are difficult to describe away from the actual demonstration on the patient

I have adopted the same " Suspensio Uteri" as more correct than " Hysterorrhapy " which is a plastic suture of the uterus, or than " Ventrofixation" or " Hysteropexy," both of which, though widely used, give a false impression of the results obtained If the operation is properly performed the fixation (*pexy*) of the uterus lasts but a short time, after which the organ is found mobile with fundus well forward in an easy natural anteflexion, and with a marked space between it and the abdominal wall to which it was attached

The casts forming the basis of this report are all of my operations between Oct 16, 1889, and May 1, 1895, and they include all the cases I have ever operated upon by the method I shall here describe as the best

In my earliest efforts to hold up the retroflexed uterus in anteposition I utilized first the cornu uteri and then the anterior face of the broad ligaments, taking by preference the round ligaments close to the uterine attachment as recommended by Olshausen

Most of these cases held well, but some eventually dropped back and the old symptoms returned The reason for this (as I pointed out in my first paper in the *American Journal of Obstetrics*, Jan 1887, p 33), is clearly that the uterus is put in a position of mechanical disadvantage when the anterior face is drawn up against the abdominal wall above the symphysis

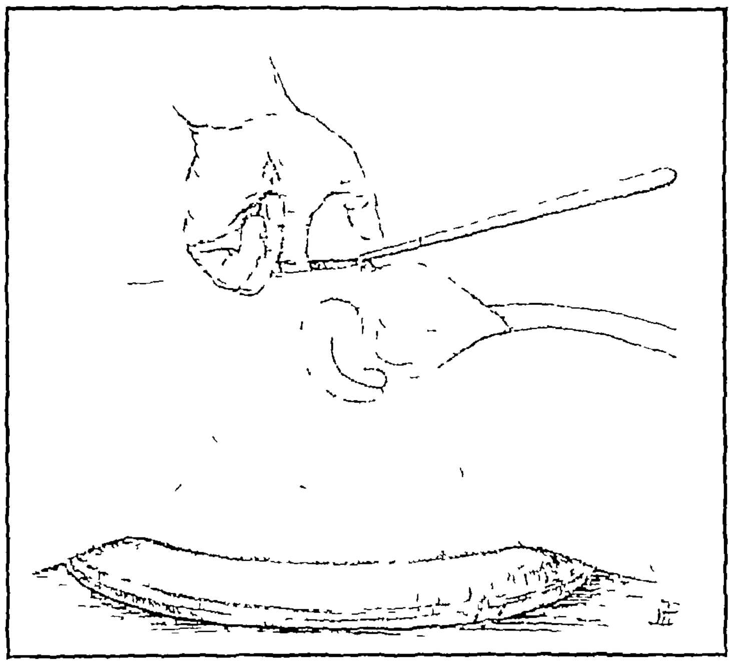

FIG 2—Elevator in and hand holding uterus in place while first stitch is passed through posterior surface of fundus

The best way to do the operation is to bring the uterus into anteflexion by passing the sutures through its posterior surface In this position a slight force will hold it better than a much larger one where the fundus thrown back by bringing the anterior face against the abdominal wall

Indications for Suspension—The indications for suspension of the uterus are the existence of a retroflexion which cannot be corrected or whose symptoms can not be relieved by non-operative treatment, such as packing, massage, and pessaries

I would use it in all those cases of retroflexion which, as Dr Beverly MacMonagle of San Francisco puts it, are more or less tied to the office of the physician by their ailment, patients who may go for years, better at times and then worse again for several weeks or more, and never feeling quite well

I would also urge a suspension where the menstrual difficulties, backache and bearing down pains, headache, loss of appetite, difficult defecation, and various general disturbances are persistent

The classes just cited are easily recognized because their pelvic symptoms are so prominent as to attract attention at once, but there is another class of neurasthenics equally important, whose local symptoms may be more or less in abeyance, and the first impression is that the neurotic condition is primary and fundamental, and the local disturbance merely accidental I know of no class of cases where a good professional instinct and good judgment come into better play in selecting the suitable case and rejecting the others

In a woman who is persistently neurasthenic, or in one who after repeated building-up efforts persistently falls back into a morbid neurotic state, where there is a retroflexion or retroposition, with definite pelvic disturbances becoming more marked at the menstrual period, I would without hesitation urge suspension

A young woman came under my care three years ago, through the courtesy of Dr I E Atkinson of this city She had been bed-ridden for four years, most of which time she had spent in a hydropathic establishment securing imaginary improvements. She was a typical hysterical neurasthenic, as she lay drawn up in bed with a miserable pinched look, apparently oblivious, but really taking in all that was going on about her

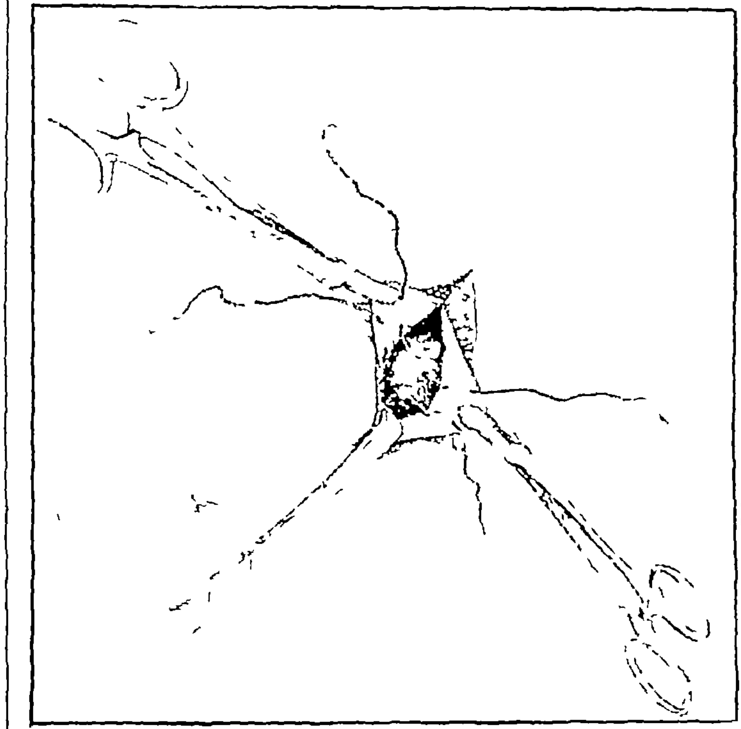

FIG 3—Two silk sutures in place in the posterior surface of uterus near fundus, not yet tied

She had that peculiar expression which is so easily read and which forbids any appeal to reason and high moral grounds as out of the question The only tangible trouble was a retroflexion, with tenderness and marked disturbances at each monthly period

I first shortened both round ligaments intraperitoneally by Wylie's method, and she began to improve in a remarkable manner, but one day about three weeks after the operation I found her again miserable and depressed, complaining of all her old symptoms Examination showed that the uterus had dropped back to its original position The abdomen was reopened and the uterus suspended by my present method She at once got better and is to day one of the finest and healthiest women mentally and physically that I have the pleasure of counting among my friends I have never seen a greater transformation in any one I would therefore operate for a retroflexion in the hysterical, neurasthenic patient with pronounced pelvic symptoms, and I would do it with the expectation of an occasional failure to give relief One cure like that above is worth even half a dozen failures, provided they entail no disability upon the patients

Operation—following is the method of operation

1 After due preparation, emptying the bladder and anesthesia, the abdomen is slightly elevated and an incision 3 to 5 cm long is made, beginning about 2 cm above the symphysis, down into the abdominal cavity

2 The peritoneum is then caught with artery forceps on each side and drawn out This is to prevent pulling in the peritoneum by the suspensory sutures and leaving none to close the incision

3 The retroflexed uterus is then hooked up and lifted into anteflexion by means of two fingers carried into the wound

4 One side of the incision is then elevated with two fingers, and the peritoneum and subperitoneal fascia caught with a curved needle carrying the suspensory silk ligatures The amount of tissue embraced is about one third of an inch wide and one eighth of an inch in depth

5 The same (ligature) is then conducted through the uterus on its posterior face below the fundus, and finally through the peritoneum and fascia of the opposite side, when it is tied, bringing the uterus up snugly against the anterior abdominal wall If the pelvis is deep and the uterus lies out of reach, it may be brought up and held in position while passing the suture, by means of an elevator such as is figured here This is introduced down into the pelvis in front of the uterus, which is pressed into it and held as against an artificial symphysis As soon as the first stitch is passed the elevator is laid aside After tying the first suspension suture, the second is easily put in, entering and emerging on the abdominal wall just above the first and piercing the posterior surface of the uterus just below the first, when it is tied it increases the anteflexion

6 The sides and front of the uterus are examined to see that no intestine is caught, and the omentum is drawn down, and

7 The abdomen is closed I do this by taking off the forceps and sewing up first the peritoneum with the finest silk, and then drawing together the fascia with one or two silver wire mattress sutures, finally closing the skin with a subcuticular suture of fine silk

The patient may rise sooner, but I find it better to keep her quiet from two to three weeks It is not necessary to wear an abdominal bandage, and I never put in a pessary afterward

It was necessary in one case to reopen the abdomen for a hemorrhage following the operation, this arose from the slipping of the ligature at the cornu uteri, the stump of an amputated tube and ovary There was no trouble from adhesions or incarceration of a knuckle of intestine in front of the uterus in any case

Out of 130 of these cases carefully analyzed for me by Dr George W Edwards for the results, within a few weeks of the operation 100 were reported well, 26 improved, 4 not improved The recovery was interrupted

By a transient mania in 3 cases, by bronchitis in 3 cases, by pneumonia in 1 case, by stitch abscess in 3 cases by hemorrhage from a repaired outlet in 1 case, by dysuria in 4 cases, by hysteria in 4 cases

The proportion between married and single women was about 2 to 1

I am not prepared at present to state the number of children born since operation There have been at least six pregnancies, and in but one was there any marked discomfort and dragging due to the attachments of the womb (*Amer Jour of Obs* 1894, p 370)

I do not know of any case in which the retroflexion has recurred after pregnancy

There has never been a hernia in any case

In women who have borne children the retroflexion is often associated with descensus and relaxation of the vaginal outlet It is useless to expect relief in these cases by simply suspending the uterus which, instead of being gently detained in easy anteflexion, simply drags on its attachments until they give way. In such cases the vaginal outlet must invariably be repaired too Sixteen out of 133 cases needed the vaginal repair In going over my statistics I am surprised to find so few needing this double operation and estimate the percentage at present as certainly much larger

In 7 cases both tubes and ovaries were removed for disease, in 9 cases one tube and ovary removed, in 3 instances I ligated either uterine or ovarian vessels, in 2 a myomectomy was performed, in 1 a nephropexy

THE DISEASES, DEATH AND AUTOPSY OF NAPOLEON I

BY EDMUND ANDREWS, A M, M D, LL D
PROFESSOR OF CLINICAL SURGERY IN THE CHICAGO MEDICAL COLLEGE
SURGEON OF MERCY HOSPITAL, ETC
CHICAGO

Napoleon has again invaded the nation, coming this time on a tidal wave of literature The magazines for two years have been full of him New books describing his campaigns have rapidly appeared, and now at last physicians are beseiged for opinions about his diseases and the causes of his death

The gigantic intellectual power of this man was such that even now, seventy-five years after his death, few writers can look calmly on his career and weigh him impartially for what he was worth They dispute about abont his acts, motives and morals, and take sides for and against him as if he were alive and still riding at the head of his armies

This folly has filled the air of history with a fog which obscures every part of his biography, medical or otherwise However, after much hard work I have so far gotten at the truth that I think I can give a substantially correct account of his diseases and of their influence on his career

The facts of his medical history mainly depend on five writers cotemporary with him, whose works are now old, rare and difficult to find, to whose accounts may be added numerous scattered facts preserved by non-medical persons

The earliest of these five writers was William Warden, surgeon on board H M ship *Northumberland*, which conveyed Napoleon to St Helena During the voyage, and for a month after, Warden was in close and friendly intercourse with the Emperor, and preserved many facts and conversations of his patient, who talked freely to him with a view to the publication of his ideas, hoping thereby to modify some of the prevailing English prejudices Warden published his little book two years later, and it was read to Napoleon by his attendants at St Helena

The Government detailed a naval surgeon named Barry O'Meara to act as Napoleon's physician at the island He was a well-educated man, as education went in those days He lived on the most friendly terms with his patient, but as he would not betray the professional secrets of the ex Emperor's acts and conversation, the Governor, Sir Hudson Lowe, was angry, so that he and the doctor got on very badly together, living in a state of illy suppressed animosity O'Meara was an honest and truthful man, but biased strongly in favor of Bonaparte He kept a faithful diary of facts and conversations for future publication, apparently with Napoleon's approval, and, as he suspected that the irate Governor would seize his sheets, he secretly sent off copies of them to England as fast as they accumulated His diary covers a period of nearly six years

Napoleon kept up a constant quarred with the Governor, whom he called a rascal, or hangman, a hired assassin, and many other names not very endearing After some five and a half years, the Governor sent O'Meara back to England, being suspicious that he secretly helped the Emperor to correspond with Europe O'Meara published his diary in 1822, a year after Napoleon's death, suppressing certain parts which he felt bound by professional obligation to keep private

On O'Meara's removal, the British Government requested Napoleon's uncle, Cardinal Fesch of Rome, to select a successor to O'Meara The Cardinal chose a Roman physician named Antommarchi, who was sent to the island and cared for the royal prisoner until his death in 1821, some nine month's after Antommarchi's arrival

He subsequently published a report, reasonably correct as to physical facts, but full of venomous hostility to the Governor

During the last two months of the patient's life Dr Antommarchi requested Dr Arnott, a naval surgeon at the island to consult with him, which he did and continued to do almost daily until the patient's death, some eight weeks later, in June, 1821 Dr Arnott's report of the consultations and of the autopsy was published He appears to have been a well educated and honorable medical man

Before his death Napoleon directed that a post-mortem examination be made, and that a report of his case be made out for his son

Eight years later, when that son reached his majority, Dr J Héreau of Paris, former surgeon to "Madame Mere," the Emperor's mother, and to the Empress, Marie Louise, carefully examined the reports of the four surgeons above mentioned who attended Napoleon at St Helena, and searched every other accessible source of information about his prior diseases and their causes This semi-official report was printed, and a copy presented to Napoleon s son when he arrived at his majority Héreau was an intelligent medical man, and though full of animosity against the English, and bitterly prejudiced against the Emperor's attending physicians, he handled the scientific facts of the case with an evident intention to be truthful

These five old books, with a few scattering facts from other cotemporary writers, contain about all that is left on record of Napoleon's medical history Naturally, the earlier allusions to his diseases are scanty While he was on the throne everything pertaining to the imperial health was a profound State secret, and for the most part his physicians were faithful to their professional obligations and died without revealing anything Héreau only wrote because the dead Emperor had commanded it, and his son and heir authorized it

Though the known facts were thus scanty, hundreds of rumors all along prevailed about his diseases and death

Napoleon himself constantly charged that he was being intentionally killed by the climate of St Helena, and left on record this sentence "I die prematurely, murdered by the English oligarchy and their hired assassins"

When the news of his death first reached Paris the wildest rumors sprung up and were believed One was that the Governor of St Helena, Sir Hudson Lowe, enticed the Emperor out for a walk and suddenly pushed him over a precipice into a chasm, when a sentinel shot him for being outside the dead-line Another stated that he was suffocated under a mattress, a third that he was strangled in his room, and a fourth that he committed suicide

Napoleon's suite returning from St Helena soon contradicted these wild stories, yet Dr Hereau, writing eight years afterward, said that it was still believed outside of Paris that he was poisoned To this day French writers occasionally speak of him as murdered by the English Dr Héreau himself says there was no murder and no suicide, but he thinks the tropical climate of St Helena was very deadly, and shortened his life

The facts about the climate are these The island is situated in the southern tropics, but the Emperor's residence was in a farm-house called Longwood, 2,000 feet above the sea, where the temperature was never above 75° F nor below 60° There were no marshes on those rocky hills, and no malaria The sea winds were unpleasantly strong, and Napoleon complained of their dampness and coolness and of the frequent showers, but the post-mortem showed that he did not die of any disease of the respiratory organs Decidedly it is a healthy climate for most persons We may therefore dismiss the climatic question with the rumors of murder, etc, and discuss more tangible facts

WOUNDS RECEIVED IN BATTLE

Napoleon's body at the autopsy showed the scars of several wounds, especially on the thighs and legs He told Surgeon Warden that he had eighteen horses shot in battle, and that he received several slight wounds which he seems to have concealed as far as possible One or two of them he even kept back from the knowledge of his surgeon, treating them himself by wrapping wet cloths around them The motive was probably this He found great advantage in giving his army the impression that he was an extraordinary and invincible being, having a supernatural star of destiny that insured victory and protected his person from death It was not judicious, therefore, to allow his troops to become too familiar with the idea that he might be shot and killed like any common man None of his wounds were serious, or left any injury to his health

HIS "MYSTERIOUS MALADY"

Field-Marshal Garnett Wolseley, present head of the British Army in his book entitled "The Decline and Fall of Napoleon," says that in his Russian campaign of 1812 the Emperor began to show the effect of some "mysterious malady" which injured his mental powers He would plan a campaign with all his old-time military genius, but when the fight was actually on, and before the close of the day, his energy flagged, he became drowsy and negligent and let the fruits of his victories slip away from him The Empress Josephine remarked that after great battles, even when victorious, he suffered great depression of spirits and expressed intense dissatisfaction with the results obtained At the battles of Dresden, Ligny and Waterloo, Field Marshal Wolseley says this mental failure showed itself plainly, and his generals noticed it On the day before Waterloo Gen Vandamme said, "The Napoleon we once knew no longer exists The victory of yesterday (Ligny) will yield no fruits" The Minister of War, Carnot, remarked in substance as follows "I no longer know him He used to be lean, shy and silent Now he is fat and garrulous He is sleepy, and his mind wanders He, the man of rapid decision, who resented the proffer of advice, now talks instead of acting, and asks opinions"

Wolseley states that at the battle of Waterloo Napoleon suffered pain in riding, and that he had a table set in the open air in a suitable position for receiving dispatches and issuing orders, where he sat for hours, much of the time asleep, leaning his head on his arms When it became necessary to get him away from the field, he was so drowsy that it was difficult to get him upon his horse

Now all his physicians agree that he was unusually abstemious in drinking, and there is not a shadow of proof that he took opium, so that his drowsiness did not arise from these causes At St Helena he was a poor sleeper, rising at three or four o'clock in the morning and using all sorts of devices to while away the unwelcome waking hours He had, therefore, no permanent lethargic disease

The truth probably is this, taking the Waterloo campaign for an example About a hundred and ten days previously he had landed from Elba In twenty days of intense labor and sleepless energy he had marched to Paris, overthrown the King and taken again his imperial throne There "he worked like a galley slave for eighty-four days," toiling fifteen hours a day to reorganize the Empire, raise an army, put down royalist uprisings, gather money ($20,000,000) for his campaign and march his troops to Belgium All this terrific labor he accomplished while suffering under a genito urinary disease which may have partly weakened his force of will He must have arrived in Belgium exhausted mentally, and physically to the verge of collapse by overwork and loss of sleep

Napoleon was not superhuman His drowsiness and illness at Ligny and Waterloo were presumably due to the above causes A medical man would hardly call his condition a "mysterious malady"

WAS HE AN EPILEPTIC?

In 1810, when Napoleon was in the height of his glory and England was full of the wildest rumors about him, one Louis Goldsmith published a book in which he gathered up every sort of story against him, regardless of its truth or falsity Among other things he said that all honest men would be glad to learn that Bonaparte was an epileptic His proof was the statement of a French theatrical actress named Mdlle Georges Weimar, who alleged that she had been called to spend the night with the Emperor at the palace of St Cloud In the course of the night he was attacked with convulsions, which so frightened her that she screamed aloud and roused the palace, causing the attendants and the royal family to rush in She stated that the Emperor, on recovering from the fit, discovered that her screams had caused the exposure, and that he drove her out of the apartment, throwing her clothes after her

Now it is not incredible that any one should have epilepsy, but the testimony of a prostitute is no proof of the alleged fact The story sounds exactly like one of the lies which prostitutes delight to tell when they seek to increase their importance by relating their wonderful adventures with great men

Goldsmith gives another tale equally destitute of authentication It is to the effect that Napoleon, walking in a partly lighted corridor, met an attendant whom he did not recognize, and that he became frightened, screamed aloud, and fell down unconscious These tales prove nothing

The only other evidences which I can find are these Surgeon Barry O'Meara, who attended him nearly six years at St Helena, mentions that on two mornings the Emperor told him that he was apprehensive of apoplexy, for he had experienced a nervous attack during the night and thought he had lost consciousness a few moments His servant thought he was faint on one of the occasions and threw cologne into his face to arouse him, causing his eyes to smart. This may have been a nightmare Dr Héreau says he was subject to twitchings of the left shoulder and of the corner of the mouth, and also at times to vertigo These symptoms might possibly be with Jacksonian epilepsy, but it is not probable

On the whole, if Napoleon were an epileptic from the date of Goldsmith's book in 1810, to his death in 1821, it must have been known to many physicians, surgeons, staff officers, secretaries, guards, valets, servants and members of the imperial family, and however faithfully they kept the secret during his power and prosperity, some of their tongues would have been loosened after his fall and death The rumors were universal on both continents, but there is probably no truth in them

HIS CUTANEOUS ERUPTION

The memoirs of the Empress Josephine state that Napoleon was "tormented" with an eruption of the skin, caught by using the rammer of a dead artilleryman at Toulon, who had scabies Bonaparte, himself made the same statement to Surgeon Warden, on the voyage to St Helena He said that at the outset of his military career, when he commanded some batteries at the seige of Toulon, two of his gunners were killed, one of whom had the itch Napoleon seized the fallen rammer and proceeded to serve the gun, whereby he took the disease, which was shortly cured by appropriate treatment This trival accident led to a pathologic error The parasitic nature of scabies was not then discovered, and as the patient some months afterward was attacked with a chronic eruption, probably eczema, which "tormented" him at intervals for the rest of his lifetime, he and all his surgeons, including Héreau, supposed that the original disease was imperfectly cured, and had "receded" or "struck in," and produced the general eczema, and also had attacked his internal organs, producing various troubles and among them the urinary obstruction Héreau says the eczema mainly attacked the outer sides of his thighs, but that when it was "driven in" by exposure to stormy weather his internal disorders became very distressing, so that the Emperor acquired a great dread of cold and wet This perhaps accounts for his leaving the field durthe rain storms at the battles of Dresden and Ligny

I assume that the eruption was eczema Josephine's statement that it "tormented" him implies that there was severe itching, which fact shows that it was not syphilitic, since eruptions of the latter disease do not itch He made free use of baths, probably to relieve the trouble, often taking his breakfast while sitting in his bath

HIS URINARY TROUBLE

During the Russian campaign in 1812, Napoleon began to have difficulty in expelling his urine It was attributed to the effect of the cold in causing a "recession" of his eruption to the internal organs It gradually got worse and continued throughout the rest of his life

In the midst of the most important business he was often obliged to retire suddenly to relive himself In field service he acquired the habit of leaning his head against a tree or a wall, and in that position with difficulty and pain forcing out his urine He seems to have suffered severely, for he once remarked to an attendant, "This is my weak part It is this which will ultimately cause my death"

These are the actions of a man who has a mechanical obstruction of the urine accompanied with cystitis The three usual causes are enlarged prostate, calculus, and stricture of the urethra He was too young to have a senile prostate Nine years after a few small calculi were found at his autopsy, but had they been there nine years they would have been very large There can be but little doubt that the trouble was urethral stricture with cystitis As his amours were very numerous, the stricture presumably had the usual origin in gonorrhea The urethra was not examined at his autopsy, but the bladder was opened It was found very much contracted, and contained a few small calculi The kidneys seem barely to have been looked at, but not opened The left one was narrower than the right, and lay turned over and adherent to the sides of the vertebra Presumably it was a kidney contracted by inflammation Nothing was known at that time about the relations of nephritis, albuminuria, and uremic poisoning Four years before his death, while his general vigor was still fairly good, he began to have dropsical swelling of the feet and legs, and as his heart was not diseased he probably had chronic nephritis The sequence of events seems to have been this

1 An attack of gonorrhea
2 A stricture of the urethra
3 A cystitis
4 Nephritis, with a few small calculi
5 Albuminuria, dropsy of the legs, and uremic poisoning in a moderate degree

This may have impaired the action of the brain and the mind, and caused some of the defects of skill in battle noted by Field-Marshal Wolseley There is no account that the stricture was ever surgically treated, yet it ought to have been, for the use of "waxed bougies" for that purpose was already well known Possibly the self-will and obstinacy of the patient prevented their application

CANCER OF THE STOMACH

For several years Napoleon had a gradually increasing trouble of the stomach which he believed to be cancer, inherited from his father, who died of that disease Apparently it had no connection with the urinary trouble He ate a reasonable quantity at meals but swallowed it quickly, often finishing in fifteen minutes He usually took at each meal half a bottle of the weak French claret, called "vin ordinaire," which shows him to have been much more abstemious as to wine than was common among French and English gentlemen of his day He said he was unable to drink freely on account of the rebellion of his stomach

As his stomach disease progressed he began to vomit, and that symptom increased to the end He had also severe pains about the liver and adjacent regions His physician, Dr Antommarchi, at length called in Dr Arnott, an English naval surgeon, in consultation, and they attended him together until his death from the stomach trouble, about eight weeks later

Napoleon left directions that a post-mortem examination should be made by Dr Antommarchi and that none of the English surgeons should touch him, or if any help was necessary Dr Arnott alone should assist

The Governor humored the dead man's whim by allowing this absurd dictation to be carried out, but he ordered five army and navy surgeons to be present and make a report of the autopsy Three other English surgeons were also present

Dr Antommarchi did the dissections and the others looked on The examination was miserably defective, but the art of making autopsies was then in its infancy Perhaps this was done as well as might be expected at that day, especially as there was no expert pathologist on the island

The report of the English surgeons differs in some minor points from that of Antommarchi, but in the main they agree

The body was measured and found to be five feet two inches and four lines in length, English measure, Napoleon being a very short man His head was twenty inches and ten lines in circumference, presumably the occipito-frontal circumference, for the reports do not state where the line was applied Héreau in some way derived the impression that the tape was applied just above the ears, and not at the usual place, around the occipito-frontal circuit The latter would have given a little larger measure Whichever it was, the head was a rather small one, in spite of the fact that the pictures of the artists generally exaggerated it, and made it look large Perhaps the very small stature made the head seem relatively large

The brain was not examined

The body was corpulent, notwithstanding the weeks of severe vomiting The fat was an inch and a half thick along the abdominal incision, and the omentum was loaded with adipose tissue

The stomach was the main seat of disease, the roof of the organ, that is the lesser curvature, was occupied by a cancerous growth, which extended from near the cardiac orifice to within an inch of the pylorus, and was lobulated along its anterior and posterior borders

Antommarchi's report calls it "cancerous ulceration" The English report describes it as "a mass of cancerous disease or scirrhus portion advancing to cancer" The phrases are obscure, but agree in the main idea of cancer The two reports disagree in the extent of it, but I have followed Antommarchi, whose observation was evidently the more precise The left extremity of the stomach and nearly all its lower curvature were healthy The cancer at its right extremity had crept around the entire inside of the stomach in a ring form, and had created there a stricture, which must have been the cause of the persistent vomiting The pyloric end of the stomach for one inch was free from the malignant growth, but its upper surface was perforated by a circular ulcer through all the coats Apparently some leakage of the contents of the stomach had at some time taken place, but a local peritonitis had stopped the effusion by causing a firm adhesion of the roof of the stomach to the liver, and of the whole upper surface of the liver to the diaphragm Incisions into the hepatic tissue showed a perfectly natural color The spleen was enlarged The lymphatic glands near the borders of the stomach were enlarged The heart was natural, the pleura showed small spots of adhesion and contained a little fluid The lungs showed only trifling diseased signs

Microscopic diagnosis had no existence in those days, but the gross facts, though badly observed and badly reported, show that cancer of the stomach caused the death, while the rather extensive local peritonitis caused by the circular ulcer assisted to extinguish the life

The tropical climate and the ocean winds, so much blamed by Héreau for shortening Napoleon's life, left no characteristic traces in the respiratory organs nor in the other viscera They did not hasten by a single hour the great ex-emperor's death

2520 Prairie Avenue, Chicago

THE LOCATION OF THE APPENDICULAR ABSCESS

BY M L HARRIS, M D

PROFESSOR OF SURGERY CHICAGO POLICLINIC

That the appendix is extremely variable in its location, and that abscesses formed about it may occupy areas widely remote from the usually described appendicular region, are facts which the surgeon who has operated often in cases of appendicitis has frequently encountered Attempts have already been made, particularly by Gerster (New York *Medical Journal*, July, 1890) and v Sonnenberg (*Deutsch Zeitsch für Chir*, Bd xxxviii, Heft 2 u 3) to classify these abscesses according to location, accessibility, etc Gerster describes five types of these abscesses, classified according to the point where they come in immediate contact with the abdominal wall, and are accessible to the knife without traversing the free peritoneal cavity

1 *Ilio inguinal Type*—The abscess lying anterio, externally beneath the parietal layer

2 *Anterior Type*—Lying more internally, in direct contact with the anterior abdominal wall

3 *Posterior Type*—Lying in contact with the posterior peritoneal wall

4 *Rectal Type*—Accessible through the rectum

5 *Mesocœliac Type*—Lying in the midst of loops of small intestine not in contact with the abdominal wall at any point

v Sonnenberg (*Deutsch Zeitsch fur Chir*, Bd xxxviii, *Heft 2 u 3*) describes four types

1 *Antero—external*—The loops of small intestine which almost always lie between the lower end of the cecum and the anterior abdominal wall become agglutinated early As the amount of pus increases these are pressed aside and the pus reaches the parietal peritoneum which forms the anterior wall of the abscess, the cecum with loops of small intestine form the posterior and upper and inner wall, while the iliac fossa limits it externally The appendix in these abscesses is usually found in front in the iliac fossa, or along the outer and lower surfaces of the cecum

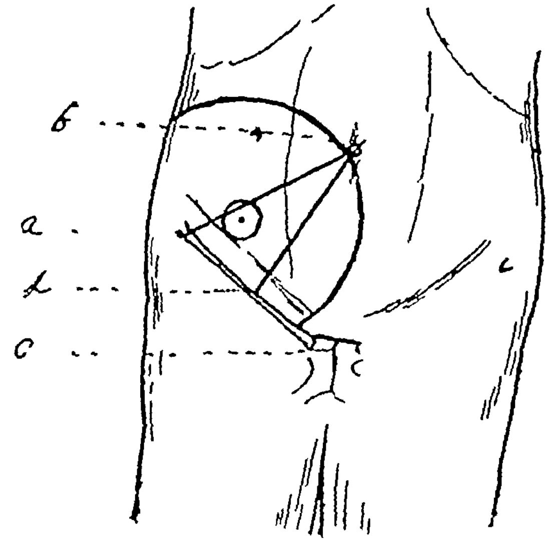

Fig 1—a ant sup spine of ilium b umbilicus c symphysis, d, Poupart's ligament

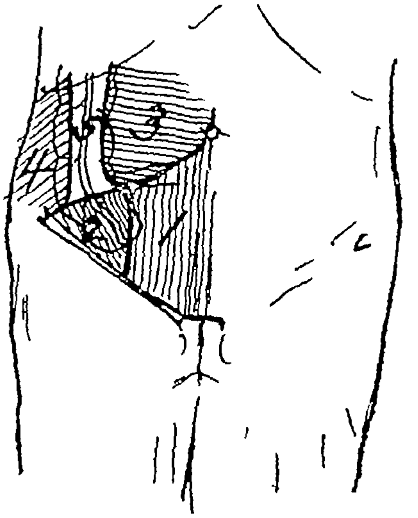

Figure 2.

2 *Posterior*—The abscess is limited in front by the cecum, and behind by the posterior abdominal wall

3 *Internal*—Abscess bounded externally by the cecum and colon, posteriorly by the mesocolon, and internally and below by adherent loops of small intestine

4 *Pelvic*—The abscess occupies the small pelvis, usually the right side or in the recto-vesical pouch in the male, or Douglas' cul-de-sac in the female

Without entering into particulars, it is sufficient to say these classifications are imperfect, some types which are quite common and possessing markedly distinctive features being omitted entirely and others imperfectly outlined Before considering in detail the various abscesses as they may appear about the diseased appendix, let us dwell for a moment on the location of the healthy organ A circle of an inch and a half in diameter—the size of a silver dollar—drawn about the center of the posterior surface of the cecum will touch the base or point of origin of the appendix in about 96 per cent of all cases It will thus be seen how constant is the location of the base of the appendix The average length of the adult appendix is 9 cms , or three and one-half inches A circle, then, of four-inch radius, drawn about the same center as our smaller circle will give us a very large area in the abdominal cavity, anywhere within which we may find the apex of the normal appendix located (Fig 1)

The appendix may radiate in any direction from its base or point of origin, although it is found to extend in certain directions much more frequently than in others

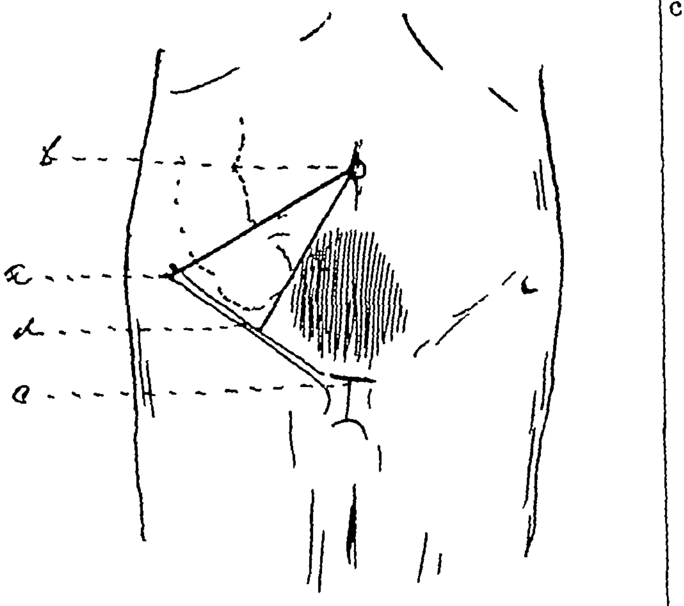

Fig 3 —Shaded part represents location of exudate or abscess as determined by physical signs All drawings are from actual cases

If we examine the anatomic relations within this large circle, we will find that the space may be subdivided into five separate areas, each having distinct and well-defined boundaries The appendix may be found in any one of these five areas, and when an abscess forms about the inflamed organ, it is the particular area in which the appendix is located which gives to the abscess or exudate its characteristic location and outline, which limits its extension in one direction and favors it in another, and which should guide us in the selection of the best point for incision and direct to some extent the technique of the operation

These areas, arranged according to the relative frequency with which the normal appendix is found to occupy them, may be thus outlined

1 *Area—infra mesenteric*—Is the space bounded above by the mesentery of the lower end of the ileum and externally by the inner and lower border of the cecum It is practically the southeast quadrant of the above described circle, and located within it we find the appendix in about 60 per cent of the cases The appendix may be superficially situated, approaching anteriorly or lie deeply on the posterior wall, it may extend directly inward, hugging the under surface of the mesentery at the ileum, or inward and downward, reaching often into the true pelvis The mesentery above prevents the extension of abscesses in an upward direction, but gives to them a tendency to extend downward and to the left

We may further subdivide abscesses in this area into three types (*a*) Those occupying the true pelvis, (*b*) in the midst of loops of small intestine (meso-celiac type of Gerster), (*c*) superficially situated near base of appendix (Internal type of Sonnenberg)

The pelvic abscesses are limited in the male anteriorly by the bladder, posteriorly by the rectum and pelvic wall and above by the sigmoid and loops of small intestine In the female they fill Douglas' cul-de-sac or occupy the ovarian region on one or both sides, where they are often with great difficulty differentiated from pelvic abscesses of tubal or ovarian origin The danger of infecting the general cavity on opening these abscesses from above is very great, and the advisability of draining through the vagina in the female, as in other septic pelvic troubles, comes into serious consideration

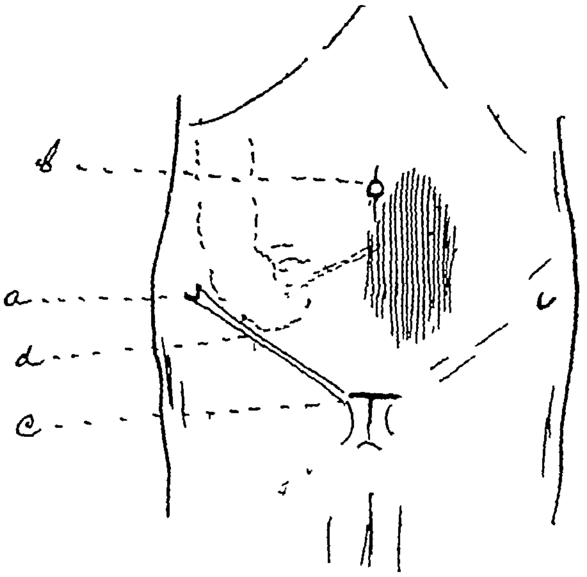

Figure 4

The inter-intestinal abscesses (Figs 3 and 4) are usually situated near the mid-line and are consequently best opened at this point Adhesions may have occurred to the anterior parietal layer so that the abscess may be opened without entering the general cavity, or there may be no adhesions whatever so that the free peritoneal cavity must be traversed in order to reach the abscess In the former case great care must be exercised in order not to open the bowel, and the greatest gentleness is necessary so as not to break down the protecting adhesions When no adhesions exist, the dangers of the case are greatly increased However well we may pack around with gauze, it is often impossible to prevent pus escaping into the general cavity, with a resulting fatal acute septic peritonitis It is in those cases that the advisability of doing a *deux temps* operation is to be considered. If the patient's condition will permit of the delay, pack with iodoform gauze for twenty-four or forty-eight hours until adhesions form, then open gently without disturbing them Should the appendix be found floating free in the abscess cavity it may be removed, but if it be firmly embedded in the exudate forming part of the abscess wall it should under no circumstances be torn out and removed, if by so doing we endanger breaking into the general cavity, thus leading to general sepsis

In the third subdivision the exudate usually comes to the surface, forming adhesions to the anterior abdominal wall, just internal to the cecum (Fig 5) The abscess is limited externally by the cecum and internally by the loop of ileum which almost always covers over the end of the cecum and the omentum They are usually best opened by a vertical incision over the inner border of the cecum Care should be taken not to separate the loop of intestine internally, particularly at its lower angle, as pus then escapes at once into the pelvis The appendix can nearly always be removed as it usually lies posteriorly or anteriorly, and it can be done without disturbing the internal wall of exudate which protects the general cavity

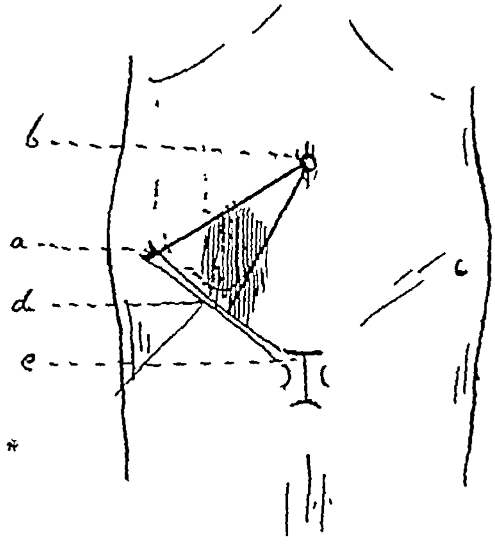

Figure 5

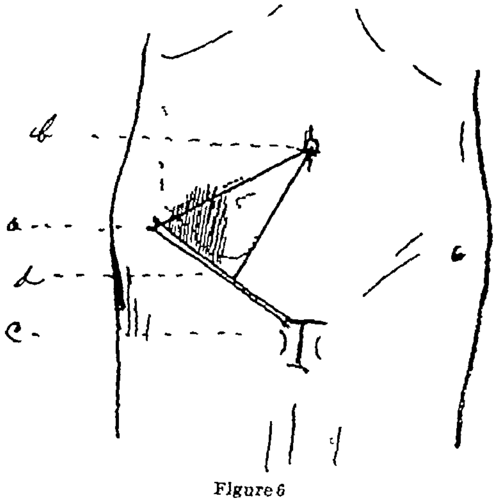

Figure 6

2 *Area—retro cecal*— Appendix lies in the little pouch posterior to the cecum, more or less curved or folded upon itself or extending downward and outward It is found here in about 23 per cent of the cases

Abscesses have the cecum in front, the same loops of small intestine internally, and the iliac fossa posteriorly and externally They come to the surface along the outer half of Poupart's ligament (Fig 6) They are best opened by an oblique incision parallel to the outer half of Poupart's ligament, coming down upon the outer border of the cecum, which should be raised up and turned inward The appendix can nearly always be removed, unless it should be too firmly imbedded in the exudate forming the inner wall

3 *Area—supra mesenteric*—The appendix lies above the mesentery of the ilium and internal to the inner layer of the meso colon (Fig 7) Abscesses are prevented from descending into the pelvis by the mesentery, they are limited externally by the meso colon and colon, and internally by agglutinated loops of small intestine They have a tendency to spread upward toward the liver, and have ruptured into the duodenum and the gall-bladder Adhesions to the anterior parietal peritoneum are the rule

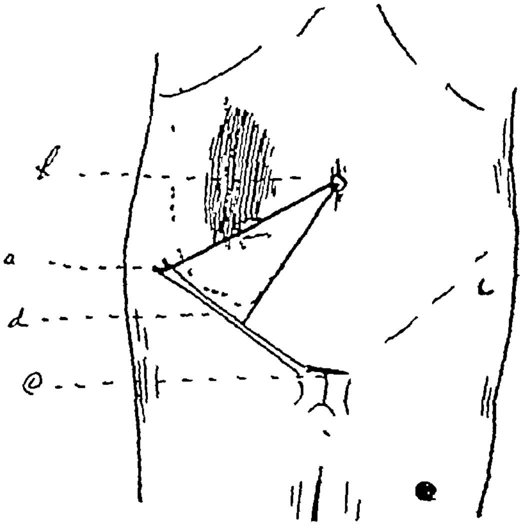

Figure 7

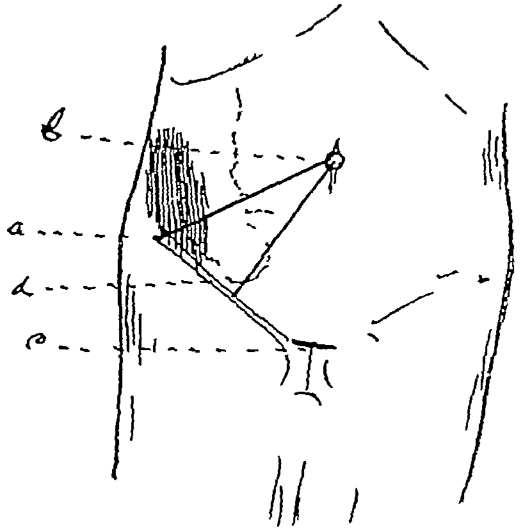

Figure 8.

These abscesses are best reached by an incision along the external border of the right rectus muscle, great care being taken not to break down the adhesions between the loops of small intestine to the inner side

4 *Area—external*—Is the space between the outer border of the colon with its outer layer of meso-colon, and the external abdominal wall The appendix may extend upward and outward into this space, its tip sometimes reaching nearly to the under surface of the liver

Abscesses here are quite characteristically defined (Fig 8), being limited internally by the meso colon and colon, which is usually adherent to the anterior abdominal wall, thus shutting off the general cavity, and externally by the parietal layer They spread upward to the liver, or even between the liver and diaphragm, and have repeatedly ruptured into the pleura and even the bronchi They may be reached by an oblique incision extending from above the crest of the ilium downward and inward, parallel to the outer third of Poupart's ligament, or, if the abscess is high up, by a longitudinal incision over its most prominent part, care being taken not to injure the ilio-hypogastric nerve The appendix can nearly always be removed, as there is no danger in separating the adhesions about it of opening the general cavity

5 *Area—retro colonic or extra-peritoneal* —In the cellular space posterior to the colon between the two layers of the meso-colon (Fig 9) Abscesses here are entirely extra-peritoneal The colon is pushed forward Pus may dissect upward about the kidney, producing a perinephritic abscess, or it may dissect downward beneath the iliac fascia and point below Poupart's ligament

The incision in these cases should be an oblique one, similar to the one described under the fourth area, but extending pretty well above the crest of the ilium

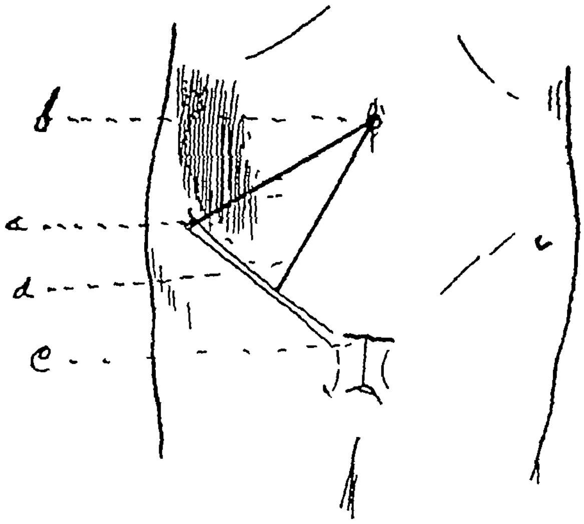

Figure 9

If it be determined beforehand that the appendix is retro-colonic, the peritoneum need not be opened, but when reached, dissected up posteriorly until the abscess and appendix are reached The appendix may be removed by this route without opening the peritoneum

If the peritoneum be opened before it is determined that the appendix is retro-peritoneal, the posterior edge of the peritoneum should be raised up and stitched to the anterior edge, when we proceed as if the peritoneum had not been opened

These five areas, having their distinct anatomic boundaries and relations, are what give to the abscesses their characteristic location, outline and direction of extension

The particular direction in which the appendix and abscess lie in each concrete case must be determined by accurately outlining the mass by inspection, palpation and percussion, and in no case should a careful rectal examination be omitted When the abscess is thus located, the best point for the incision becomes apparent and this should at all times, when possible, be made in a manner respecting the muscular layers and the direction of their fibers

THE VALUE OF PUPILLARY CHANGE IN SPINAL AND BRAIN DIAGNOSES

BY JAMES A LYDSTON, M D , Ph G
Ophthalmologist to St Joseph's Hospital Lecturer on Diseases of the Eye and Ear, Chicago College of Physicians and Surgeons Member of the American Medical Association Fellow of the Chicago Academy of Medicine and President of the Alumni Association of the Chicago College of Pharmacy
CHICAGO

The intimate relationship between the brain, the spinal cord and the eye, leads us to infer that the pathologic processes implicating the eye should enable us to diagnosticate various morbid processes primarily asserting thenselves in the spinal cord and brain And while we possess certain data more or less positive in their character, among which pupillary change is prominently figured, we are not always able to define positively by the disturbed pupillary reflex the site of such pathologic processes It seems, however, that an outline of the pupillary changes consequent upon spinal or brain lesion that are definite in character, should prove advantageous to the general practitioner as well as the ophthalmologist, consequently we will enumerate, as far as practicable, the diseases of the cord and brain with their accompanying pupillary changes which are conspicuously significant and explain their etiology Since the pupil is nothing more than a circular opening in the iris, it follows that this structure is an active participant in cases involving pupillary changes, and as the iris is intimately associated with the sympathetic, it is not strange that brain and spinal diseases should be associated with pupillary changes Thus spastic mydriasis is a condition which accompanies cerebral irritation arising from various causes, while a much more frequent type of mydriasis—paralytic mydriasis—due to paralysis of the oculo-motor fibers which innervate the intrinsic ocular muscles, namely, the ciliary muscle and sphincter pupillæ, which are usually both involved in oculo motor paralysis In this case the paralysis may be diffuse, that is, affecting several or all of the branches of the nerve or it may be isolated in character, implicating the pupil or in conjunction with the ciliary muscle Such paralysis occurs in syphilis, in chronic cerebral affections, or is toxic in origin Under the latter category we note the effects of the various mydriatics and those cases of absorbed products of putrefaction styled ptomaines, septicemia, etc

We have certain traumatic forms of accommodative paralysis, associated with pupillary dilatation, ascribable to local injury of the sphincter pupillæ and ciliary muscle In contused injuries, consequent on concussion, we frequently observe small lacerations accompanied by extravasations of bloody serum, etc , into the muscular structure, while increased tension causes paralysis by reason of pressure upon the sensitive nerve filaments, and, if unrelieved, atrophic changes eventually supervene Pupillary dilatation accompanying amaurosis is not dependent upon motor disturbances, but is rather a cessation of the physiologic pupillary reflex due to modified illumination

With respect to myosis, or contraction of the pupil, we note that spastic myosis, so called, occurs as one of the prodromal manifestations of meningitis, whereas, locally applied, the several myotic remedies of which eserin is the type, while pilocarpin ranks second, induce marked spastic myosis, while other poisons, such as chloral hydrate, opium, nicotin, stramonium, etc , likewise induce pupillary contraction And it is well to note here that paralytic miosis is a suggestive symptom of implication of the cervical sympathetic, paralytic in character, and is commonly noted in spinal lesion, especially tabes dorsalis And it is in this connection that the so called Argyll Robertson phenomenon finds its most fitting application, i e , the pupil fails to react to light, while it reacts synchronously with accommodation and convergence We must always remember that enlargement and contraction of the pupil do not perceptibly impair vision unless accompanied by accommodative paralysis To Horner belongs the credit of having first outlined the symptomatic phenomena characteristic of sympathetic paralysis, and he notes the following

1 Pupillary contraction due to paralysis of dilator fibers, which is determinable by shading the eye

2 Narrowing of the palpebral fissure as a result of drooping of the upper lid, which in turn is due to a paralysis of the smooth muscular fibers in this situation, called the musculus palpebralis superior of Muller, innervated by the sympathetic

3 The eyeball is perceptibly sunken and intraocular tension is lowered, while the fourth and most important sign is the notable fact of a variable fullness of the vessels on the two sides

Thus, in recent cases of paralysis, the face is flushed and warmer on the paralyzed side, while the contrary obtains in the later stages, the paralyzed side being cooler, blanched, and devoid of sweat, which is readily determined by inspecting the sweat-band of the patient in question

The underlying or predisposing causes of sympathetic paralysis are groupable as follows

1 Traumatism, such as accidental injury and operation wounds implicating the nerve in the neck, while central lesions are at the bottom of a percentage of cases Spinal cord lesions, e g , tabes and injury of the upper cervical portion of the cord, are likewise responsible in certain cases Since pupillary contraction is dependent upon the sympathetic, which receives its pupillary fibers from the ciliospinal center of the cervical spinal cord, it follows that irritation of this center or of the cervical sympathetic induces pupillary dilatation, and its paralysis or division pupillary contraction, while the same is true of the oculo-motor nerve, i e , stimulation of the oculo-motor nerve causes pupillary contraction, its section or paralysis pupillary dilatation, and inasmuch as pupillary reaction is either reflex or associated, and if it be reflex the necessary impulse emanates from centripetal nerve channels extending to the iritic nerves, and if associated arises from the pupillary fibers of the oculo-motor nerve which are agitated simultaneously with other oculo-motor nerve fibers, it follows that, excluding toxic influence of whatever cause, any abnormal pupillary change arises from pathologic conditions involving either the oculomotor nucleus or centripetal nerve centers, intimately associated with the iritic fibers

And since the nuclei of nerve fibers which act simultaneously, namely, the sphincter pupillæ, accommodative and convergence centers are closely related in the brain, being situated in the anterior extremity of the oculo-motor nucleus, it follows that any morbid process involving these centers will exhibit itself by abnormality of the pupillary reaction, combined possibly with disturbed activity (on part) of the extrinsic ocular muscles which preside over convergence, and in turn we can approximate the site of the pathologic process with comparative certainty by remembering the course of the fibers, emanating as they do from the oculo-motor nucleus, observing a downward course from the crus cerebri to the base of the brain, at which point they unite to form a single trunk opening at the anterior border of the pons varolii, extending thence through the cavernous sinus and superior orbital notch to the orbit Total abolition of the functions of the sphincter pupillæ, convergence and accommodation always signifying total destruction of both motor oculi nuclei or their ramifications The abducens and trochlear nerves which likewise are characterized by separate partial nuclei, after reaching the base of the brain, pass forward similarly to the oculo-motor nerve, extending through the cavernous sinus and superior orbital fissure into the orbit

Paralysis of a single ocular muscle with but one exception—ptosis, which sometimes occurs in cortical disease—always indicates that the site of disease is below the intracerebral tracts, that is, the cerebral cortex, association centers and their connecting fibers It is notable that in uremic amaurosis the pupillary reaction is intact, which points to the fact that the disturbance is located in the brain, i e , above the eye and optic nerve Atrophy of the optic nerve accompanying tabes frequently announces itself by pupillary change which asserts itself by the Argyll-Robertson phenomenon, in which the pupil still reacts to convergence and accommodation, but not to light, and is usually contracted, which, in conjunction with the test of Westphal, i e , the absence of the tendo-patellar reflex and its bilateral character, constitute diagnostic signs in the early stage of many cases of tabes

THE IMPORTANCE OF EARLY DIAGNOSIS IN SOME FORMS OF NERVOUS DISEASE

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY IRVING C ROSSE, A M , M D , F R G S
WASHINGTON D C

Only a few days since I was forcibly struck by the remark of one of my patients, now in the advanced stage of locomotor ataxia with progressive cortical changes, who tells me that on meeting his former physician he had refused his proffered hand, for the reason that he was one of several who for years had treated him for what they incorrectly took for rheumatism However questionable the act may be as regards politeness, there can be no doubt of its import to the patient when looked at from a diagnostic view-point Had the patient been treated by a skilled neurologist it is reasonable to infer that his condition would not be so lamentable as it is to day

I do not mention this incident in the way of fault-finding or unkind criticism of any one, but it seems hardly credible, in view of the numerous warnings from neurologists, that so many general practitioners who do not hesitate to recommend their patients to oculists, gynecologists or other specialists, should take a jump in the dark when a neurologic question is involved

Some years ago, one of my efforts was a paper presented to the American Neurological Association at Long Branch, in which I called attention to the frequency with which chronic, inflammatory and degenerative affections of the spinal cord are incorrectly diagnosticated and treated as rheumatism, even by practitioners otherwise well informed The observations therein mentioned, showing notable failure of diagnosis, consisted of cases examined for medicolegal reasons and each case was accompanied by more or less voluminous written testimony of physicians who have recorded such diagnoses as chronic rheumatism, rheumatism and heart disease, rheumatism and disease of the eyes, malarial poisoning, disease of the liver and spleen, sunstroke and resulting loss of sight, general prostration and debility, sciatica, and other vague pathologic generalities The certificates of disability were written by medical men from widely distant parts of the United States, and by surgeons of the Army and Navy Many of the patients in question have since died, and one having committed a criminal offense was, in my opinion, unjustly sentenced to penitentiary

Being a frequent occurrence in my own experience, my mind is filled with recollections of tabetic material where the attending physician has taken refuge in such a generality as malaria, or more commonly, the effects of grippe It is only necessary to relate a few examples by way of specification

A short time since I was called in consultation to see a young man who for several years had been actively treated for malaria Upon the advice of physicians he had taken much exercise, but growing worse, finally broke down on attempting to ride a bicycle I found the poor fellow in an advanced stage of locomotor ataxia, with gastric crises and trophic change of the stomach He lived but a short time

The second case was that of a United States Senator, whose wife was highly incensed at my diagnosis, although it was afterward confirmed by two of the best neurologist in New York During the last days of the Senator's illness he came under the care of a general practitioner who, to my surprise, tells me that he did not notice or examine for tabetic symptoms, and that the distinguished consultant he called in from Baltimore attributed most of the symptoms to the liver

In the third case, of a woman under the care of a general practitioner who had come to the end of his therapeutic tether, I found the patient with an alcoholic history, and in the last stage of sclerotic tabes On informing her husband of the hopeless character of the case, one of the numerous irregular practitioners who infest the National Capital was accordingly called in and proceeded to apply electricity, with which he claims to have cured twenty cases of locomotor ataxia A few days later, in looking over a newspaper I noticed the death of the patient

So far, indeed, has the notion of malaria been carried, that a few years ago a public man in Washington died of what was supposed to be malaria, contracted at the mouth of the Ganges river on a tour around the world, but which in reality turned out, at the necropsy to be cancer of the stomach

Occasionally, however, we find a man who has the scientific courage to say, "I don't know," and forthwith sends his patient to a neurologist, as was lately done in the case of a highly respectable woman suffering from paralysis of the extensor muscles of the left leg She attributed this condition to a sprain, but the extension of the paralysis to the opposite leg, and my familiarity with the patient's habits, led me to suspect alcoholic neuritis Under appropriate treatment she made a good recovery

In another case, of a young girl who had arrived at the age of puberty, but had never menstruated, I was called to witness what was supposed to be an obscure case of nervous disease of ovarian origin A slight strabismus with abdominal tenderness, and information from the attending nurse that the patient picked her nose and scratched her anus, exploded all notion of a "fancy" diagnosis and led to but one inference, namely, that of worms Suggesting this to my professional confrére, he relucantly wrote a prescription for an anthelmintic The morning following the administration of the medicine the intestinal parasite came away, the nervous symptoms rapidly disappeared and the patient made a good recovery

In connection with this subject I may mention the case of a small boy who was brought to me from one of the adjoining counties He had been under homeopathic treatment and had, on an average, ten epileptic seizures every day The symptoms indicated worms. After appropriate treatment he was two weeks without a manifestation of epilepsy, which entirely disappeared, and I have no knowledge of its recurrence

Quite different was the case of a comely young woman who consulted me several years ago for a variety of obscure nervous symptoms Something in her face suggesting an unhappy love affair, I asked if she was suffering from anything of the kind, to which she answered in a hesitating and evasive way that led me to suspect her truthfulness After some weeks of treatment she made but slow progress and I finally lost sight of her until a year afterward, when she came to my office and after much hesitancy and embarrassment told me that she had a confession to make, which was simply this An elderly woman, a so-called Christian scientist, had been using her for purposes of tribaism, and this woman had obtained such an influence over her as to break up many social and domestic relations, besides ruining her health As the woman had quitted Washington, my patient did not feel the restraining influence that formerly kept her from telling me this bit of personal history I saw nothing more of my patient for several months, when happening to be waiting for a train in a railway station in Paris, I saw her with her former old associate in crime, from whom she probably could not stay away I mention this case for the reason that one of the oldest practitioners in Washington remarked at the reading of a paper on sexual perversion, that he did not think the cases so common as I had reported, or he would have seen them This is one of many cases that have since come under observation or have been reported to me by other physicians

Much remains to be said on early diagnosis of that vast subject of epilepsy There is no disputing the fact that a small proportion of cases of this protean affection may yield to early and careful treatment I say protean in speaking of this terrible neurosis, for nothing could be more incongruous than the symptoms that go to make up a diagnosis in such apparently different attacks as that of epileptic vertigo, an attack of *grand mal*, or a manifestation of epileptiform mania

However much may be said upon the feasibility of early diagnosis of epilepsy by a person having the necessary technical requirements, its importance is a most serious matter in questions of forensic medicine, since the mistakes of a medical expert are more grave in their consequences than those of the ordinary practitioner

In the last year or two, in the District of Columbia, we have had sad examples of questionable legal proceedings in cases of aphasia, paranoia, and epilepsy, in which irresponsible individuals, exhibiting a morbid degradation of a suffering organism and morality in ruins, have become the victims of judicial predilection and the sentiment of the hour

The recent case of *Taylor*, an epileptic wife murderer, who also shot himself over the heart with suicidal intent, may be cited as a case in point In this case, hereditary predisposition and domestic chagrin were predominant features The father was a consumptive and the mother a paralytic, the significance of which is evident, if we accept recent statistics which show that in about 50 per cent of epileptics there is a family history of some nervous or pulmonary trouble Besides epilepsy the accused had a history of sunstroke, he had a scalp wound in the upper part of the frontal bone, and a depression from a horse-kick about the vertex of the skull, the pupils showed a want of responsiveness to light and accommodation, and ophthalmoscopic examination showed a choked disk The pulse was 130, sitting, he was neurasthenic and tremulous, had exaggeration of the reflexes, and insomnia Eroticism was another salient feature in the history, as the accused says that he missed copulation but thirty nights in five years Nymphomania seems also to have prevailed on the other side of the house

Viewing these facts and the proved infidelity of the wife, is it astonishing to any one, with even a small knowledge of psychiatry that the stress induced thereby should lead to impulsive and delirious acts of fury, such as suicidal and homicidal attempts, or even wife murder? At least ten instances of the latter crime committed by epileptics may be cited In fact, it may be said that no epileptic can be a kind and loving husband, because of egotism, suspicion, irascibility, and a tendency to violent and instantaneous impulses, and it is no temerity of language to say that some of the greatest crimes that have shocked human nature have been committed by epileptics It is not pretended that every epileptic is a candidate for insanity Nor is it denied that history furnishes instances of great epileptics, as Cæsar, Mahomet, Peter the Great, and Napoleon The alleged epilepsy of the last-named is, however, open to doubt If not digressing, I may say that having lately spent some time in France my attention has been called to evidence that inclines to the belief that the assertion is utterly without foundation

But, to come back to the case under consideration, in which I testified for the defense, the question of the prisoner's suicidal wound being brought in by the counsel, I was asked as to my experience in the collection of facts as to gunshot wounds, to which I answered that my experience was probably larger than that of any other man in the United States As this statement may seem strange in coming from a neurologist, I must specify the facts upon which it is based In addition to seeing numerous gunshot wounds in various military hospitals around Baltimore and Washington, during the Civil War, and in Europe after the Franco-Prussian campaign, I also handled, studied and described, thousands of specimens in the Army Medical Museum, where I was employed for several years as one of the collaborators of the surgical history of the war, and after that I examined for the Pension Office many thousand gunshot wounds of all kinds in applicants for invalid pension In stating to the court the result of my examination of the prisoner, I said "I came to the conclusion that he was a man of unsound mind and not sufficient master of his own actions to enable him to choose between right and wrong in the offense for which he stands indicted" The term "unsound mind," which appears to have caused the court considerable embarrassment, is herewith used advisedly, since it is used by the best medico legal writers and also appears in the newest legal authority, the "English and American Encyclopædia of Law" Dr William A Hammond and others testified substantially to the same thing as myself Yet an outsider hired by the government, whose chief qualification seems to be that he is an insane asylum superintendent in Pennsylvania, took the stand, and in testifying to the sanity of the accused, totally ignored the post-epileptic mental state and, among other amazing assertions, declared that there is no such thing as the clinical reality known as nocturnal epilepsy

Testimony of a similar nature was given in the case of *Beam*, who murdered his stepdaughter After about fifteen minutes' examination by the forementioned asylum superintendent, he was pronounced sane and handed over to the gallows, notwithstanding the fact that numerous lay witnesses swore to his insanity As this unfortunate man was too poor to employ medical experts in the way of rebuttal, I was asked, as a matter of charity, to examine into his sanity with a view to securing a new trial I learned from trustworthy sources that the father has been a senile dement for thirteen years in a public institution, and that the mother is a woman of irascible disposition, whose conduct has been erratic and suggestive of unsound mind The history of the accused showed the turbulent career of a paranoiac, who was influenced by such delusions of religiosity as reading sermons to cattle and to the dead in unfrequented graveyards, and in the still crazier notion of building a stairway to the moon, and of reforming all the prostitutes of Baltimore, one of whom he married by way of practical application

I found the prisoner of indifferent physical development with congenital deformity of the thorax, and syphilitic In addition to physiological signs of degeneration, the mental stigmata were marked There was not the slightest attempt at concealment or simulation, although the prisoner talked freely and somewhat incoherent He had a number of immovable delusions, one as regards a cat, another as to untold wealth in a gold mine he had discovered in Maryland, a third in regard to hypnotism, and a fourth as to poison, and there was a tendency to obsession

The main objection to granting a new trial on this case appears to hinge on the phrase "unsound mind," which though used advisedly in my affidavit seems to have a source of embarrassment to the court The term, "unsoundness of mind," employed by the latest and best authorities both in forensic medicine and law, is in fact of legal adoption and one that is preferred by lawyers to the term insanity, which they have come to look upon with suspicion

In the contested will case of Wallis vs Suhring, 134 Ind 447, in which unsoundness of mind and undue influence were alleged, the court instructed the jury adversely as to the term unsound mind, yet they found for the contestants, and on appeal the Supreme Court affirmed the judgment Seemingly imbued with the "wild-beast theory of insanity" and the residuum of by-gone legal superstition, which not so long ago considered it right to hang the innocent old witches of Salem, the court, in attempting to be its own insanity expert, utterly ignored the more advanced teaching of science Assuming these teachings to be true it is, therefore, not the perfection of reason to deny the meeting link between science and law, nor is it wise to reject their application to the purposes of justice

Something of the same spirit seems to have tinctured the mind of the bench in the case of the paranoiac, *Schneider*, some medico-legal details of which case I have recorded elsewhere[1] It is, however, only fair to the judges to say that they were largely influenced in this case by the unfortunate opinion of the medical experts employed by the government, who, in the light of subsequent events were shown to have been utterly mistaken

The foregoing cases furnish striking instances of the non-recognition and disregard of medical expert evidence by the average citizen, and, at the same time, stand in bold relief as judicial inconsistencies when contrasted with the *Sickles* case or that of the Treasury Department murderess, *Mary Harris*, who, a short time since, married her senior counsel In the District of Columbia, without a law to regulate the practice of medicine, charlatans and all sorts of mediocrities prevail to such an extent that the community at large show no discrimination between an educated medical man and a quack Consequently, in public estimation, the opinion of the so called doctor is just as good as that of the able and experienced In Germany, where the pig-headed and brass-handed rule of blood and iron comes down heavily, they manage such matters differently Owing to the civic spirit which pervades public and scientific men of that country, so much heed is given to medical intervention in matters of the kind under discussion, that of late we read of lust-murderers being declared insane, when we all know that such persons in the United States would not only meet with no mercy in court, but would, in all probability, become summary victims of a disorderly mob of lynchers

Many persons, however, say in reply that any consideration shown the defective individuals of whom we speak is harmful to society, and that, as a class, they are best disposed of after the manner of mad-dogs, which we do not hesitate to kill on the ground of public safety While such proceedings may obtain in American pioneer communities, a quarter of a century behind Europeans in realizing certain municipal and criminal problems, it is doubtful whether any argument can justify similar steps for the protection of society in these days of growing civilization and Christian enlightenment The horror inspired by crime calls for just indignation, but the pity felt for atavistic degradation and neurotic constitution of the insane, instead of being false sentimentality is in accord with the more enlightened civic ideas now rapidly spreading in our country

Aside from the personal responsibility affected by medical facts like the foregoing, the interpretation of many sensory, motor and trophic symptoms may bear upon questions of civil incapacity Moreover, other instances of questionable diagnoses come under the observation of the neurologist in which his work encroaches upon that of the surgeon Spasm or paralysis of the muscles are often erroneously named as causes of natural or structural defects, or mechanical injuries to the joints causing loss of motion, as witnessed in torticollis or in "angel-wing paralysis" Again, how many physicians overlook the apparently trivial and insidious prodromata of general paresis, the brain-fag, neurasthenia and polyuria of the overworked business man, and it may be asked, do ophthalmogists, as a rule, give due weight to the diagnostic importance of the condition of the eye-grounds in the matter of some chronic cerebro-spinal affections?

Although I have in this paper spoken of but a few nervous diseases, the idea I wish to convey relatively thereto applies forcibly to many other conditions What shall we say of the late diagnosis of appendicitis, cirrhosis of the liver, desquamative nephritis, and other medical and surgical affections where life may have been prolonged or saved by an early diagnosis? In fact, neurologic science can not be divorced from questions of diagnosis, so intimate are its relations with all other branches of practical medicine

My experience, in common with that of most neurologists, is that the diseases here mentioned are not recognized as early as they can and should be when due care is given to their semiosis In the matter of forensic medicine the questions in which diseases of this class are concerned are simply those of clinical diagnosis, and if we wish to help justice to make the best disposal of the irresponsible criminal, according to the more humanistic ideals of the present day, or if we expect to arrest or cure such dismal and discouraging cases as those afforded by the decay of the nerve elements, we shall never regret the attention and painstaking that enable us to make an early diagnosis

NOTES ON THE NATURE AND TREATMENT OF CHOREA BASED ON SEVENTY-FIVE CASES IN PRIVATE PRACTICE

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10, 1895

BY A D ROCKWELL, A M , M D
NEW YORK

If an apology is necessary for presenting for your consideration a subject so hackneyed as chorea, the nature of which so many able and careful observers have attempted to solve and about which discussion and theory have been worn threadbare, it is 1, that any disease, the source of so much anxiety and distress as chorea, can not be discussed too frequently 2, that my experience has been somewhat large and has been gleaned entirely in private and not in hospital practice, upon which nearly all considerations in regard to this subject are based, and 3, if I can not offer anything new in regard to medicinal or hygienic methods of treatment, I am in a position to speak with some authority and confidence upon the methods and results of electrical treatment, a subject even yet in its relation to this disease too little understood by the profession in general and almost altogether ignored by both teachers and writers on nervous diseases I have long desired to give the impressions of many years' experience in observing the course of chorea and treating its symptoms, and the invitation that I present before the Neurologic Section something pertaining both to neurology and electro therapeutics, affords me the opportunity that I have often wished for

---

[1] See Virginia Medical Monthly, Feb , 1895, also JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Feb 2, 1895

Chorea has by common consent been put in that class of diseases that presents no constant detectable change in any of the structures of the body, and is therefore termed functional in character It is, however, more than doubtful whether a functional disturbance, however slight and evanescent, can exist without corresponding disturbances in the nutrition of the nerve elements Microscopic changes have, it is true, been occasionally found, but not with sufficient frequency to enable us to rely on morbid anatomy to account for the disease, and the nutritive changes that in all probability do take place are too subtle for detection and may perhaps ever remain conjectural Age and sex, in their relation to chorea, tell us far more of its nature than all methods of post-mortem examination

The fact that chorea is almost entirely confined to early childhood and youth and occurs with far greater frequency in girls than in boys—in the emotional period of life and mostly in the emotional sex—renders it probable that the disease is in the vast majority of instances purely functional, dependent upon disturbances or shock to the motor centers of the brain To illustrate I once had under my professional care a young girl suffering from what appeared to be a slight neuritis of the radial nerve On one occasion she was suddenly asked a question in regard to certain facts which she desired to conceal In her efforts to disguise any appearances of surprise her facial muscles immediately passed beyond her mental control, and for a few moments the localized movements exactly simulated the familiar examples of facial chorea It was an excellent example of temporary chorea, having its source in a temporary disturbance in the cerebral convolutions

Neurasthenia is a functional disease, and it may be either acute and temporary or chronic and permanent Just as the fatigue and irritability of mind and body that accompany profound and concentrated mental and physical effort are dissipated by rest and sleep, so the familiar examples of lost muscular control following sudden emotional influences, disappear on the subsidence of the cause In both cases we have to do with facts of cellular nutrition, in the one case with temporary exhaustion, in the other with temporary irritation

Intensify and prolong the processes of cell exhaustion and cell irritability and we get in the one case true neurasthenia and in the other true chorea Another reason for rejecting structural change as the causative factor of chorea, lies in the fact that so far as we have knowledge, there exists no structural changes of the nervous and muscular system that will in itself produce chorea Embolism to which it has been ascribed produces, so far as we know, symptoms of a far different character It is associated with head-pain, vertigo and nausea—at least at its outset—hemiplegia of varying degrees of severity, and when right-sided, with aphasia together with other disturbances of speech Then it must be remembered, how serious are its sequelæ, how apt it is to recur and to what extent nutrition is impaired The occasional presence of embolic particles found in fatal cases of chorea hardly offers sufficient basis for such a theory But that chorea must be regarded as a disease of the central nervous system, either primary or secondary to peripheral irritation can hardly be questioned As all movement, as well as all thought has its origin in the brain, it is inconceivable that disordered muscular movement such as characterizes chorea can depend upon peripheral influences alone In deference to our inability to point out objective pathologic changes, we sometimes speak of the psychic origin of chorea, yet in the last analysis we fall back on disturbance of the motor cortex

In a large proportion of choreic cases, especially among the poor, anemia exists, and in another large proportion of cases fright is the exciting cause Sometime ago a child was brought to me suffering from "nervousness" and extreme anemia I prescribed what seemed to be necessary and for a time saw no more of her While engaged on this article the mother again returned with the child, suffering now from an acute and violent attack of chorea, the exciting cause of which was fright These two elements of causation, fright, acting upon a nervous system weakened and irritable through its vitiated blood supply, seem to me to give great strength to the theory of malnutrition of the cortical ganglion cells as the seat and the efficient cause of chorea The analogy existing between certain nervous diseases that are attended by no definite and positive vasomotor changes are interesting and suggestive Influences, the same in kind that result in diabetes when acting on the nervous system of a man, result in hysteria when acting on the emotional nature of a woman, or in chorea when on the tender and susceptible nature of a child

Conflicting as are the opinions relating to the pathology and the treatment of chorea, there are certain facts in regard to the disease upon which all experience agrees Like Basedow's disease whose pathology is as doubtful as that of chorea, it occurs far more frequently in the female than in the male In my own experience, its exciting cause in the majority of cases can be traced directly to fright or other emotional causes, and in this again it bears some resemblance to Basedow's disease With increasing years the disease rapidly decreases in frequency and becomes far more intractable, and even dangerous to life

Notwithstanding my belief based upon these seventy-five closely observed cases, that the majority are in their essential nature central—although neither organic nor structural in the ordinary acceptation of these terms—yet a few have seemed to me to depend upon reflex influences, both as exciting and continuing causes Peripheral sensory irritants, such as a redundant prepuce with collection of smegma, intestinal worms and ocular defects have all within my own experience been the undoubted cause of chorea In the case of a redundant prepuce, an operation performed by Dr Charles McBurney, at my request, resulted in the prompt recovery of a case where the symptoms had been persistent for several months In a second case, where I finally suspected worms to be the cause of persistent choreic symptoms in a boy aged 8, a dose of santonin resulted in the expulsion of no less than ten of the common round worm, and all of considerable size This patient also promptly recovered In a third, a case of ocular defect, an operation by Dr Geo Stevens resulted in too prompt an alleviation of the symptoms to allow of any doubt as to its direct efficacy But reflex influences are altogether exceptional, according to my experience, in the production of chorea

Where the causes above enumerated exist once, in in connection with choreic symptoms, they occur a thousand times without any such connection It is the pseudo-choreas, the various habit-spasms that seem to be most benefited by correcting the anomalies of the ocular muscles and errors of refraction, and not the ordinary true chorea of childhood

Notwithstanding all the investigations of and the statistics offered by those who have written upon this subject, I have been unable to satisfy myself that between rheumatism or endocarditis and chorea, there exists any constantly direct relation as cause and effect The frequency with which a soft systolic murmur is found associated with chorea must be admitted, and also the results of post-mortems showing endocarditis and the presence of vegetations on the cardiac valves, but these relations have been analyzed with sufficient thoroughness to leave little doubt but that they are mostly accidental, even if in certain statistical tables they are found with suggestive frequency In epilepsy, in anemia, in the muscular relaxation associated with certain neurasthenic cases, we not infrequently detect a cardiac murmur, the same apparently as the ordinary choreic murmur While these murmurs may be and probably are due in many, it not most cases, to mitral regurgitation, yet they speedily disappear with no permanent structural harm The temporary defective action of the mitral valve is believed to be due to altered nutrition or innervation Certainly, the functional derangement of the action of the valvular apparatus is sufficiently evidenced by the readiness with which the murmur disappears as the disease improves

If rheumatism is the efficient cause of chorea through the action of its sequel, endocarditis, then it is hardly necessary to say that the endocarditis should precede the chorea On the contrary, it precedes it only in a small proportion of cases when they are associated, and in a large number of cases no evidence of endocarditis can be found As a reflex cause, endocarditis may occasionally be responsible for chorea, as are defects of the eye, or intestinal worms, or redundant prepuce, but, like these irritants, it may and does exist a thousand times without any relation to it whatever Most of the cases that have come under my observation have been carefully examined for evidences of heart disease, and in more than one-half of them there could be found no murmur of any kind and in only a very small proportion was there any history of aches or pains that could possibly be attributed to rheumatism

One of the strongest arguments against the rheumatic origin of chorea is the fact that, as related to boys, girls suffer from chorea in the ratio of three to one, while rheumatism affects boys far more frequently than girls Of the fifteen among my own cases of chorea that gave a history of rheumatism, ten were boys and only five girls These observations are very much in accord with those of Meyer[1], who, out of 121 cases, found that only 9 per cent had rheumatism, 13 per cent heart symptoms and 2 per cent the two combined, and with those of Leroux[2], who, out of eighty cases of chorea found only five clear cases of rheumatism and fourteen with heart complications Of these last, five were mitral lesions and nine simple anemic and extra cardiac souffles

Much stress is often laid upon the degree of disturbance of the mental function in chorea My observation of the disease as it occurs in children who are well cared for, both as to mind and body, is that there is seldom any mental defect Sometimes a young child will seem dull without really being so, and the parents and friends of the unfortunate little patient will act along this false hypothesis to the child's detriment In chorea, the muscular movements are not in harmony with the will The child, knowing herself unable to give correct expression to thought and desire, manifests, in the presence of strangers especially, a distrust and timidity not in accord with an acute mental state, while the operation and condition of the mind as registered in the facial expression is observed and misinterpreted because of the constant facial deformity The imperfect muscular coordination occasionally extends to the vocal apparatus, rendering the speech somewhat indistinct and jerky In other cases the patient talks very well when once started At first, the lips may be seen to move, but it is several seconds before there is any articulate sound One of the brightest children I ever knew had this symptom and, for a time, was credited with being below the normal level mentally There is a class of choreic cases very commonly met with, where the incoordination of movement is ordinarily slight, but when conscious of observation the muscular disturbance becomes exaggerated There is another class where a contrary condition exists The movements are greatest when the patient is at play and unconscious of observation, but by an effort of will the child can control these movements

It is among patients of the first class that mental defects are most often thought to exist, these cases are, however, far less apt to be dull than those of the second class, and recover with greater rapidity I do not find that ordinary chorea is distinctly or directly hereditary, but among the better classes, at least, it will be found that in an unusually large number of cases the child inherits a neurotic tendency This neuropathic heredity is said to be in the proportion of about one-sixth, but in my own experience it is much greater The theory advanced by Garrod that the rheumatic poison occasions a temporary overgrowth of connective tissue in the nerve centers, resulting in chorea, has little to recommend it, but the infectious theory about which so much has been said has points of strength both from an anatomic and a bacteriologic standpoint, since there is found in the nervous system a special bacillus pathogenic for microbes Bacteriologic and experimental researches have been made by Pianese[3] in fifteen acute cases of chorea In three of these cases a bacillus was isolated from the blood, and inoculation caused the appearance of the disease in dogs In the opinion of this author, the theory of the infectious origin of chorea is far more satisfactory and complete than all other theories Triboulet[4] has reported three cases of secondary infection by the staphylococcus in chorea, and gives it as his opinion that, in four fifths of the cases infection could be traced as the causative factor of the nervous trouble [5]

[4] Revue Mensuelle des Maladies de l'enfance, Paris, Dec 1891

But however suggestive the various theories and investigations as to the nature of chorea, nothing is more certain than that no constant pathologic change is associated with it, and we must fall back upon the theory of its neurotic functional origin Its almost benign nature and tendency to recover is the strongest evidence that it can depend upon no serious or persistent pathologic change

As regards the therapeutics of chorea there is much to be said, both from the standpoint of those who believe in the necessity and efficacy of therapeutic measures and from that of others who look upon it as practically a self limited disease which recovers as readily without as with treatment Self limited it is not, in the sense that we speak of the self limitation of scarlet fever or measles

We can not abort or very much, if at all, cut short the course of these diseases but that measures can be adopted for the relief of associated symptoms or the arrest of complications is admitted We can, however, not only very markedly alleviate the severity of choreic disturbances in aggravated cases, but can do what can not be done in the so called self-limited diseases—shorten the duration of the disease In regard to certain hygienic and sanitary methods of dealing with chorea there is very little diversity of opinion It is agreed that rest is a most important factor in most cases, and in those more serious the rest should be complete and continuous In several of these severer cases, where arms and legs and facial muscles are in constant motion, I have noted marked alleviation of the symptoms follow prolonged rest in bed

In the less severe cases, moderate exercise in the open air is allowable and beneficial, but in no case should a child with chorea be allowed to engage in rough and tumble sports Sleep, and much of it, is essential, and when it is greatly disturbed we are justified in aiding it by hypnotic measures The food should be nourishing but simple If the appetite be poor, it is allowable and even desirable to tempt it by daintily prepared food of judicious selection, but to attempt to stimulate appetite by artificial means is even more unjustifiable in the case of a child than in that of an adult Far more harm than good is done by forcing food, when nature cries out against it

The reflex effects of ether spray to the spine, or better still perhaps, of the chlorid of ethyl has been highly recommended and my own personal experience with it has, on the whole, been favorable While in some cases it may appear to do no good it can certainly do no harm, and occasionally I have seen unmistakable benefit follow its use

To enumerate all the internal remedies that have from time to time been advocated almost as specifics in the treatment of this disease, would only serve to indicate the limited data of experience upon which opinions are based Few of them have stood the test of time and trial, and the general opinion is that medicinal treatment is extremely unsatisfactory By this, I do not mean to say that in individual cases we may not be reasonably sure of the efficacy of certain remedies in alleviating symptoms and shortening the duration of the disease There are, indeed, well authenticated cases of long duration that have persistently resisted various accredited methods of treatment, and finally recovered promptly upon the adoption of some other old or some new and untried remedy

A notable illustration of this is related in Reynold's "System of Medicine," where a distressing choreic affection of the muscles of the neck had existed for nine years, defying all measures for its relief Hypodermic injections of arsenic were attempted with almost immediate relief and final recovery But I would say that there is no consensus of opinion as to which of the many drugs used is the most effective Arsenic has undoubtedly the preference, but proves too often absolutely inert There can be no question, for example, of the authenticity of the case just alluded to, and, encouraged by the success in that instance, I thought to duplicate in an obstinate case somewhat similar in character, by the same method of treatment, but without the slightest result

Now, although I have from time to time tested nearly all the well recognized remedies in the treatment of chorea, yet there is one remedy that I have used with more or less persistency in almost every case, and that is electricity I am not so credulous as to suppose it to be curative or even markedly beneficial in every case Occasionally, on the contrary, it has seemed to be contra-indicated, although long experience inclines me to the belief that this seeming susceptibility to the current is due more to a failure to correctly differentiate in the selection of the kind of electricity used than to any adverse idiosyncrasy present

In the light of my own personal experience in the treatment of chorea, the opinion expressed more than a quarter of a century ago by a distinguished physician is of much interest "Electricity," he says, "is another agent which requires a passing mention in this place, though all that can be said respecting it is, that as yet there appears to be little or no reason for placing any confidence in it as a means of treatment Whether this will always be the case, whether there are not modes of using electricity which will have the effect of quieting choreic and analogous movements, remains to be seen I suspect that there are such modes, and that they will be beneficial, but I have not yet the facts to justify the expression of a belief on the subject" [6]

Electricity benefits chorea on the same principle that it benefits neurasthenia or hysteria and many other functional nervous diseases, because of that indirect improvement in nervous force which is a part and a result of the general improvement of nutrition While electricity is neither life nor nerve force, it aids in sustaining both life and nerve force as do light and heat, not by direct transformation, but indirectly through its influence over nutrition This influence over nutrition, together with musculo-sedative effects, are brought about in greater or less degree by various methods of electrization, by general faradization, especially with the high tension coil, central galvanization, static electrification and even by peripheral galvanization To obtain temporary musculo sedative effects, there is no method that equals the depolarizing method of central and peripheral galvanization, by which is meant the elimination of either one or the other pole In this way the neutral point is thrown outside the body, and the part or parts brought under the influence of either the negative or positive pole alone as desired Static electricity (positive) is also sometimes useful in chorea in calming nervous excitement and as an aid to nutrition

---

[5] These de la Faculte de Paris

[6] C B Radcliff M D F R C P On Chorea 1868

But the two methods that I have found, on the whole, to be the most effective in the treatment of chorea are central galvanization and general faradization These two methods properly differentiated and used either alone or in alternation, according to the indications in each individual case, are capable of doing much, not only in alleviating the violence of the choreic movements, but in shortening the duration of the disease

A somewhat useful point in the way of differential indication for the use of the two currents and the two methods of application, which has been forced upon me by repeated observation, is the following For children of full habits and in that excellent condition of general health which we not infrequently see among the victims of chorea, the galvanic current is to be preferred For those, on the contrary, who are weak and anemic, with impaired nutrition, the faradic current is far more grateful, and is followed by better results, both immediate and permanent

EPILEPSY CURED BY TENOTOMY OF THE OCULAR MUSCLES

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore, Md , May 7-10 1895

BY WALTER B JOHNSON, M D

PATERSON, N J

J H H , 23 years old, consulted the writer on Sept 5, 1889, stating that he suffered from a very peculiar form of disease of the nervous system for which he had been examined and treated during the past two years by a large number of prominent physicians He was in good physical condition, attended to his business as a salesman regularly, and had no discomfort, except slight headache, until the attacks for which he wished treatment came on, two years ago , since that time, at intervals varying from two weeks to two months, he had had attacks, the onset of which was a violent headache coming on suddenly and without any premonition and followed by loss of all conscious mental action The patient had no recollection, when recovering from the attack, of anything except the intial headache The time during which he remained in the state of conscious mental inactivity varied from two to five days , during this time he would, if the attack seized him on the street, have been able to care for himself as in such cases he invariably had sufficient money remaining to indicate the expenditure of enough only to have paid expenses during the time which was a blank to him On returning to conscious mental activity he generally, upon awaking in the morning, found himself in some hotel in the city which he had not been accustomed to frequent If the attack seized him at home the improvement in the headache, which occurred generally in two or three hours, was followed by a profound sleep which lasted until the following day, or in extreme cases, two days, the headache frequently returning on the morning of the second day When the stupor passed away he was able to resume his work as usual

The physicians consulted by him differed in opinion regarding the nature of the attack, Dr A L Loomis and the major portion diagnosing the disease epilepsy, while others considered it neurotic and only epileptiform in character

Upon the recommendation of his physician, he concluded to consult further with a view to excluding any abnormal ocular condition as an etiologic factor in the production of his disorder He applied for treatment in September, 1889 The case was of such marked interest that a consultation was considered advisable, and the several consultants reported the details of their examinations as follows

Dr Herman Knapp, New York Slight dynamic inversion not verified with prisms for near

Dr David Webster, New York R , 25 D C ax 90°, esophoria 2° in acc L , 25 D sph ; exophoria 20° , abduction 5° Under atropin, R , 50 D C ax 90° c, 0 50 D c ax 180° L , 0 25 D sph

Dr Geo T Stevens, New York, before and after atropin R , 0 75 D C ax 180, esophoria, 5° L , 0 75 D C ax 180, abduction 2°, later 0°

Homonymous diplopia The result of the examination of the writer was : R V , 20-30 — 20-15 1 D c ax 180 L V , 20-15 — 20-15 w 0 75 D sph

With this correction, the lines upon the test chart for astigmatism were all of an equal density and thickness, the vision normal Esophoria 5° , abduction 5°

Homonymous diplopia at distance The diplopia was not present at the near point, either with or without the correcting glasses, which were ordered and the patient directed to wear them continuously R , 1 D C ax 180 L , 0 75 sph

For some time after the glasses were prescribed and worn the patient was decidedly improved, his general condition was much better and he had none of the attacks previously described Finally, the primary effect of the glasses passed away and the epileptic seizures returned with as much frequency and force as previously existed The partial tenotomy of the internal recti muscles advised by Dr Geo T Stevens was then performed The eyes were tested immediately after the tenotomy and showed a slight degree of exophoria The patient was directed to wear his glasses continuously and report He remained in the city for two months, during which time there was no return of the attacks herein described , although he at times suffered from headache, he had none resembling those which occurred at the onset of an epileptic seizure, nor any stupor or loss of conscious mental activity following

April 23, 1895 In a letter written from his present home in Chicago, he states that he never has had any attacks of epilepsy since the last record, and is a different person from the one I knew in this city

---

A RETROSPECTIVE VIEW OF THE TREATMENT OF HEMORRHOIDS

BY N H HENDERSON, M D

SURGEON LAKESIDE HOSPITAL CHICAGO

It is only within the past few years that diseases of the rectum have received the attention to which they are entitled Until about twenty years ago the only possible source of relief from hemorrhoids was the clamp and cautery or the ligature To attempt any surgical operation was considered very dangerous, and, in fact, we have evidence of many cases where fatal hemorrhage was the result of surgical procedure Surgeons approached the field with timidity, and during our college course instruction pertaining to diseases of the rectum were the exception, and not rule, and were mainly confined to prescriptions for some palliative ointment, with no assurance, nor even expectation of cure It is an acknowledged fact that the first step forward in the treatment of hemorrhoids was the hypodermic injection of carbolic acid, or any styptic that we saw fit to employ The regular practitioner was slow to accept this innovation, owing to its origin in the hands of the itinerant, but the success of the measure at length compelled the recognition of the profession For at least eighteen years my associate, Dr E H Dorland, has treated hemorrhoids by the method of injection and continues the practice in suitable cases up to the present date The next step toward reformation was the Whitehead operation Then Dr E H Pratt reversed the "Whitehead" and gave it prominence under the name of the "American" To recapitulate, we have the clamp and cautery, the ligature, the Whitehead and the American, to which I wish to add the operation described by me in the Journal of the American Medical Association of Feb 23, 1895 A brief notice of the above operations may at least enable the inexperienced operator to decide which he wishes to employ The clamp and cautery are entirely unsatisfactory, because you can not make a complete section of the diseased area, consequently it is but a few months, or years at best, until your patient returns to you suffering with hemorrhoids and the operation must be repeated Some patients will submit to the ligature, but if for no other reason than that the ligature is unscientific, unsurgical, uncleanly and one of the greatest sources of infection possible in this class of work, we are not, nor have we ever been, justified in using, but the results for permanency (if the patient survives) are better than those of the clamp and cautery The hypodermic injection is a vastly more satisfactory procedure, I have employed it hundreds of times, and in a certain class of cases I seldom fail to obtain the most gratifying results A recent investigation of cases treated in this way by Dr Dorland and myself, covering a period of eighteen years, demonstrates that of 1,800 cases treated by injection of a styptic, only about 15 per cent have suffered any return of the trouble As for the Whitehead and American operations, to mutilate unnecessarily any part of the human anatomy is something to be regretted, if not by the physician, at least by the patient In dissecting off the pile-bearing inch together with the integument at the verge of the anus, laying bare the sphincter ani, dragging down the loosened bowel and stitching it to the integument, we bury all the delicate nerve fibers that impart sensation to the sphincter beneath the bowel, which, being out of its normal location, can not and will not replace the original tissues Those having been submitted to these operations, have, I say without exception, a clumsy rectum, nearly devoid of sensation In cases where union between bowel and skin is complete there is a band of cicatricial tissue, which feels to the touch like a wire ring, and which completely encircles the anus and sadly interferes with the functions of the sphincter Again, we meet with cases where, having encroached too freely upon the integument, the operator has dragged the bowel down and out to repair the loss, to the end that the patient goes through life with his clothing rubbing against a portion of his anatomy which nature never designed to be so exposed But I must repeat that the greatest and most serious objection to these operations is burying the terminal nerve fibers of the sphincter beneath a part of the bowel which is almost devoid of sensation I am speaking from personal experience, having employed all of the methods mentioned, and I am not moved to these remarks by a personal motive alone, but hope that I have been able to recommend something better What I should recommend as an ideal treatment for hemorrhoids is hypodermic injection, where the patient can not go to a hospital, but where hospital care is not out of the question, I would advise the operation described in the above-mentioned journal I have made this operation no less than eighty-seven times, and in no case have I been disappointed in the result, either from stricture or loss of sensation, nor have I failed to obtain a complete restoration of the normal mucous membrane In three of the cases I failed to get the posterior incision (which was original with Dr Dorland) quite deep enough, the result of which was rather more contraction than I anticipated, but not sufficient to materially interfere with the normal function of the sphincter

NEW INSTRUMENTS

INSTRUMENT CASE, STERILIZER, SPONGE BASINS AND TRAYS COMBINED

BY E C DUDLEY, M D
PROFESSOR OF GYNECOLOGY NORTHWESTERN UNIVERSITY MEDICAL SCHOOL GYNECOLOGIST TO ST LUKE'S HOSPITAL,
CHICAGO

The apparatus herein described is designed to lighten the burden and add to the safety of surgical work in private houses, especially in the country From an experience of about two years in its use, the author offers it with confidence in place of the septic instrument bags, the unwieldy sterilizer and the cumbersome trays and sponge basins which make up the usual *impedimenta* of surgical practice outside of hospitals The apparatus fulfills the requirements, first, of an aseptic instrument case, second, of a steam sterilizer, third, of instrument trays and sponge basins It consists of two rectangular sterilizers made of copper, nickel plated, in which may be packed all instruments and other appliances requisite for an abdominal section, or for any other ordinary surgical operation Its component parts may further be used separately as pans, sponge basins and trays The whole outfit, inclosed in a washable canvas cover, is 16 inches long, 9 inches wide, 12 inches high, and when packed ready for an operation weighs about 25 pounds (See Fig 1) This canvas-covered instrument case contains a complete set of instruments, towels, sponges, ligatures, sutures, dressings, aprons, nail-brushes, soap, ether, chloroform, alcohol, antiseptic drugs, rubber sheet, douche bag, etc The equipment is adapted for work anywhere It especially solves the problem of septic surgery outside of hospitals, whether at the house of the prince or of the pauper

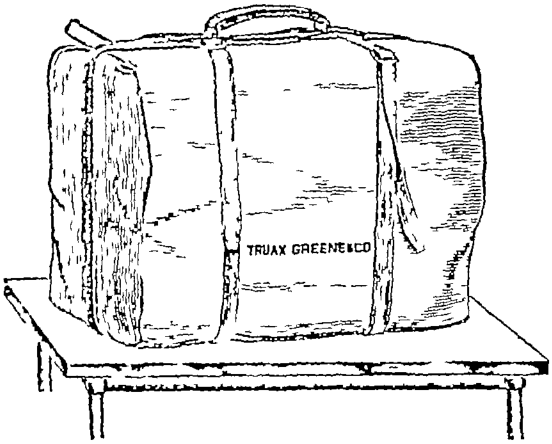

FIGURE 1

Fig 2 represents the two rectangular copper boxes as they appear under steam when used as sterilizers Observe that each sterilizer is supplied with four legs, which may be folded against the sides of the box when the box is not in use as a sterilizer Each box contains two gauze-wire trays, as shown through the broken side of the sterilizer in the right hand cut of Fig 2 The lower tray is one inch above the bottom of the sterilizer and contains instruments The upper tray, resting upon the lower, contains towels, dressings, ligatures, etc The space of one inch between the bottom of the lower tray and the bottom of the sterilizer that is below line A B, Fig 2, is filled with sterilized water The small trays D and G are filled with burning alcohol These trays are set upon saucers to prevent burning the table top The burning alcohol converts the water into steam, which sterilizes the contents of the wire-gauze trays One of the two detachable handles resting on the table between the two trays may be used to put out the flame by lifting the small alcohol tray in contact with the bottom of the sterilizer These detachable handles are also designed for use in separating the different parts of the sterilizers after the sterilization is complete

towels, gauze sponges, dressings, etc , which have been sterilized in them The two small, square, shallow cups which contained the alcohol now become trays for needles, ligatures and other small appliances (See Fig 3, H and G) Observe that this sterilizer is quite as well adapted for sterilization by boiling water as by steam After the apparatus has been under steam for thirty minutes, especially if this process has been repeated three times on consecutive days, not only its contents, but also its various parts which are to be used as sponge basins and trays are

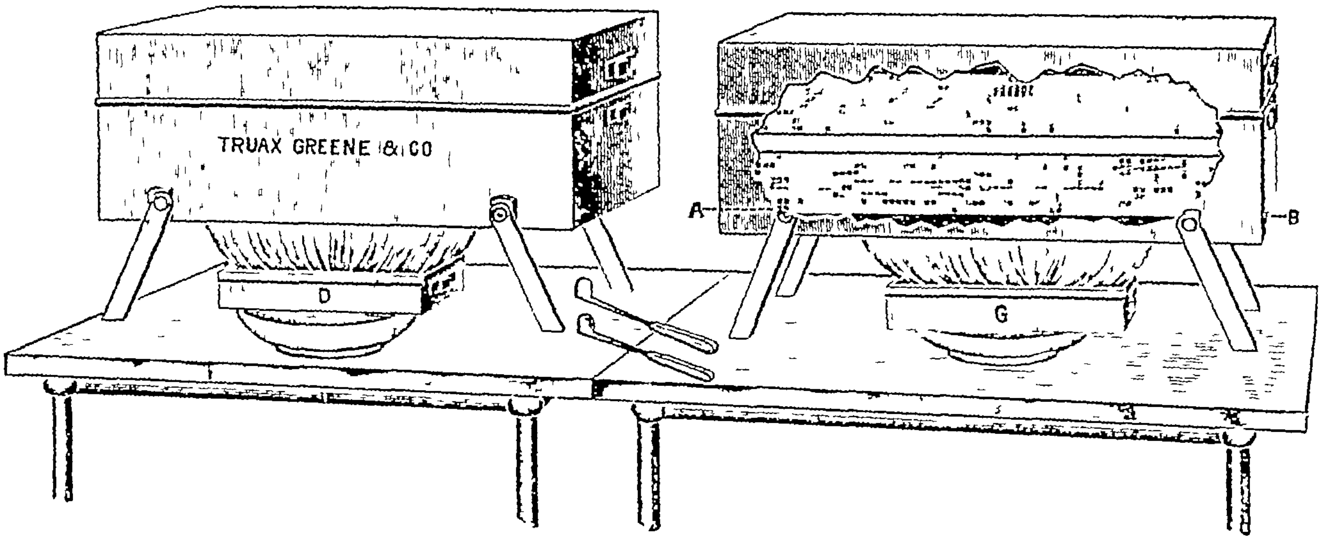

Figure 2

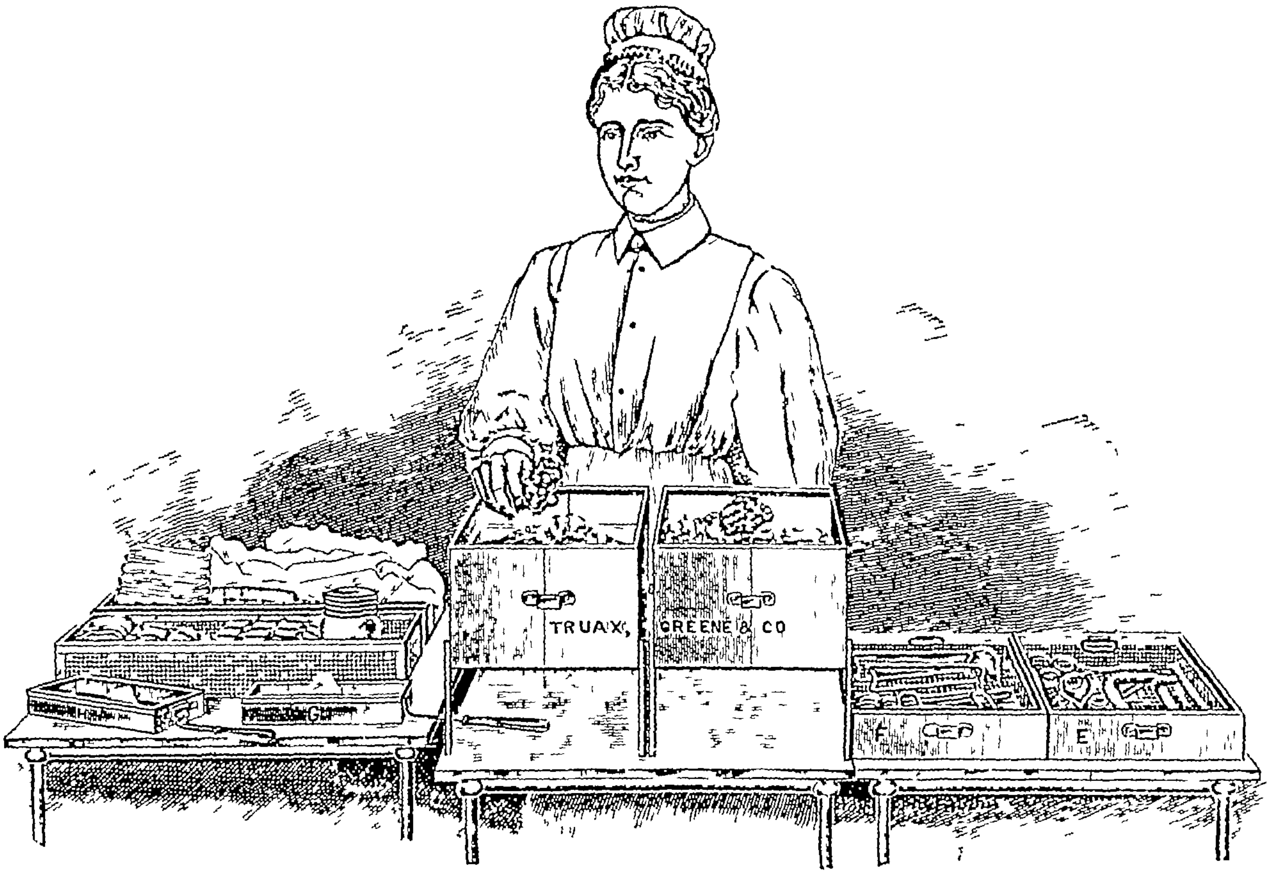

Figure 3

Finally, the several parts of this apparatus may be broken up into sponge basins, pans and trays The two large copper boxes become sponge basins The two top covers become trays, holding sterilized water, inside of which the two gauze-wire trays containing the instruments are placed (See Fig 3, F and E)

These gauze trays may be lifted out and placed in the covers without handling the sterilized instruments before the operation The other two gauze trays to the left of the sponge basin (Fig 3) hold the thoroughly sterilized Each member of the apparatus is supplied with one or more slots or rings, into which fit the detachable metallic handles already mentioned These handles are useful to separate the sterilizer into its several parts while hot, and to avoid unnecessary handling After an operation, even upon a septic case, all the parts of the apparatus may be washed and then sterilized by boiling in a large washboiler The boiling water should contain 2 per cent of carbonate of soda

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Henry P Newman Venetian Building Chicago Ill , sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor* and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago

SATURDAY, DECEMBER 21, 1895

THE RE ASSEMBLING OF SCHOOLS

The health authorities of our Northern cities where diphtheria is prevalent could do a great deal of good by causing an examination to be made of the throats of children in the public schools at the opening session after the holidays

Children found with commencing sore throats should be returned to their homes to be placed under the care and surveillance of a physician, and thus one of the great causes of the propagation of diphtheria removed

It is well known that during the holiday season many of the ordinary restraints are removed, and household isolation of the sick is but imperfectly maintained The examination suggested would not only detect suspects, but cases of actually advanced disease when found might have the exudate examined twenty-four hours earlier than would be the case where the usual custom prevails of waiting until the general and local symptoms were fully developed

If we are ever to stamp out diphtheria, it must be by preventive measures of the sort indicated, not by reliance on curative therapeutics The alleged brilliant results of serum-therapy should not blind the eyes of the people or the profession to the greater triumphs of applied hygiene

DR HAROLD C ERNST says [1]

"The disease was at its highest at the beginning of the systematic use of the bacteriologic diagnosis and inspection of schools in December, 1894 From that time, month by month, there was a steady fall, sharper than occurred in previous years, until the slight rise that apparently always appears in May, just before the schools are closed for the summer

"Of the inspection of schools it may be said, that it has happened more than once that a child has been sent home for a slight sore throat, and that cultures have shown the presence of virulent bacilli from one to three days before the clinical diagnosis of diphtheria was in any way justifiable "

We do not concur, however, with DR ERNST s further view that this state of facts renders " cultural diagnosis " more advisable as a matter of routine On the contrary, the direct attack on the bacillus, as recommended by LENNOX BROWNE, would seem in every way safer and much more effective

However, whether one worships the new-born serum therapy , views it with skepticism, or even with distrust, there can be but one opinion as to the propriety of prevention of the disease by means of frequently repeated medical inspection of the schools, early diagnosis and prompt treatment

Let the School Boards and the health officers harmoniously proceed in this work, and not only will the closing of schools be prevented, but the disease itself be circumscribed in its devastations, if not in time absolutely stamped out

THE EVOLUTION OF OUR KNOWLEDGE OF TYPHOID FEVER

Before the discovery of the pathogenic microbe, typhoid fever, called also dothinenteritis (Trousseau), continued fever, etc , was characterized Anatomically, by specific lesions in the small intestine, especially in PEYER's patches, with concomitant changes in the mesenteric glands and the spleen , clinically, by continued fever of a definite type, by intestinal and nervous symptoms, by splenic tumefaction and a discrete eruption of lenticular rose-colored spots [1]

It seems very probable that this disease was known to the older authors, but it is very difficult when studying the epidemics of the time to clearly distinguish it amidst the chaos of pyrexias belonging to typhoid, to typhus and to malaria This confusion lasted for a long time and the writings of FRACASTOR, BAILLOU, SPIGELIUS, SYDENHAM and WILLIS give but vague and unsatisfactory allusions

In 1739 HUXHAM, in describing a disease which he called " slow nervous fever" gave the first clinical differentiation of the disease Very soon the epidemics of Lausanne (1754–5) and of Gottingen (1760–1) furnished the opportunity for new observations, and the descriptions of BORSIERI (1785) and of STOLL became more and more precise About this time the pyretologists, with their innumerable divisions, observed the question temporarily For instance, the symptomatic classification adopted by

---

[1] Medical Communications of the Massachusetts Medical Society Vol XVI No III 1895 p 720

[1] Legry, L Union Medicale 1895, No 87

PINEL (1798) in his "Nosographie des Fievres Essentielles," obliges one to hunt through four or five chapters to find a complete account of the disease

However, pathologic anatomy threw fresh light on the subject, and PROST (1802) and PETIT and SERRES described the intestinal lesions in different stages of the disease in detail These authors were soon followed by CRUVEILHIER, ANDRAL and BRETONNEAU Thus material was accumulating both from clinical observations and anatomic findings to establish the autonomy of typhoid fever and mark its place in nosology

In 1829 LOUIS[2] gave a full account of the symptoms and morbid anatomy of the disease under consideration, and gave it the name of "fièvre typhoide," which was adopted shortly after by CHOMEL and is now classic The natural history of this disease being fixed by narrow boundaries, the malady was defined by its symptomatology and by its anatomic lesions The physicians of the time were free to occupy themselves with questions of pathogeny and etiology with great profit to its therapeutics and prophylaxis Let us see the changes of opinion before the question of etiology was fixed on its present firm basis

The first important theory concerning etiology was that of contagion Affirmed by LEURET (1828), BRETONEAU (1829), GENDRON (1834), it nevertheless had numerous opponents, and CHOMEL, ANDRAL and LOUIS, after long discussions on the subject, rejected it completely In 1849, though, the memoirs of PIEDVACHE furnished proof positive of the contagious nature of the disease

The discrepancies between the various authors may be explained by the different conditions experienced by the observers For instance, this phase of the question is nearly impossible to discover in large cities, while in small places it is very much in evidence Thus FORGET says "I have denied the possibility of contagion until a stay in the country has shown me beyond question that typhoid fever may affect persons living near the patients"

The possibility of contagion alone did not seem to solve the question entirely, for many practitioners, while admitting contagion, noticed facts which led them to believe we might also have an autochthonous spontaneous origin of the fever The pythogenic theory of MURCHISON (1858) is the most positive expression of this view According to this author the infectious material may come from any putrefying animal matter whatever "The disease may arise independently of any former case by fermentation of fecal matters, and perhaps in fermentation of other organic matters"

BUDD, on the contrary, a champion of the specific nature of this disease, maintained (1856–73) that every case of typhoid fever is the product of some former case A forerunner of later-day bacteriologists, he claimed that the morbid principle was eliminated with the diarrheal discharges, which disseminated the contagion to a distance and impregnated the soil Its diffusion is such, he said, that one patient may infect an entire town if the dejecta get into the wells He also showed that transmissions may occur through the air

PETTENKOFER's famous theory on the oscillations of the ground water (1854 5), which was so much in vogue in Germany at one time, does not seem to make much use of the facts concerning pollution of water in fecal emanations I do not know the cause of the disease, says this author, but believe I can connect it with the variations in the level of the *ground water in wells These variations allow the* subterranean waters to moisten the soil, and on retiring leave it damp It is when it is slightly moistened that it becomes dangerous Too much dryness of the soil or too much moisture prevent the development of the disease The new adaptation of this theory to micro-biological views does not seem to be any more convincing, and the doctrine of maturation of germs regaining their virulence in moist soil has not prevailed against that of transmission by potable water

Hence we have two great currents of opinion in the scientific world Some, with MURCHISON, admit the production of typhoid fever *de novo* "It is the despised spontaneity of the living organism," said PROFESSOR CHAUFFARD, at the Paris Academy of Medicine in 1877, "which dominates all the etiology and all the pathogeny of typhoid fever" STICH was one of the first to give an interpretation of the spontaneous theory by supposing that every individual carries materials for putrid intoxication in his intestine, which are constantly neutralized in the normal condition, but which under certain circumstances cause typhoid infection This was the opinion of PROFESSOR PETER also, who believed that the disease was manufactured by the patient himself, that autotyphisation was nothing but the results of retained waste matters in an exhausted organism

The opposite school, led by BUDD, believed, as we have seen in the specific nature of the disease, that every case arises from some previous case The discovery of the EBERTH-GAFFKY bacillus greatly facilitated the solution of the problem

EBERTH in 1880 was enabled, by using new coloring methods, to determine some of the morphological characters of the bacillus However, some doubts still remained as to its specific nature, notwithstanding the confirmatory observations of KOCH, MEYER, FRIEDLANDER and LETZERICK The discovery was completed by GAFFKY in 1884, who, by using new solid media, was able to isolate the microbe and study the form of the colonies, etc., on gelatine, potato and other materials.

---

[2] "Rech sur la mal connue sous les noms de gastro enterite, fièvre putride," etc

So, from the vague theories and fanciful discussions of the humoralists and the pyretologists of olden times, we arrive at our modern conception of typhoid fever, which CHANTEMESSE defines as a general disease which is produced by the reaction of an organism invaded by the bacillus typhi-abdominalis.

THE CAUSES OF OLD AGE

A few years ago a pseudo scientific paragraph was traveling through the public press stating that an Italian physician had succeeded in detecting and cultivating the bacillus of old age—the cause of senile decay. As a skit at the microbic theories of disease then just achieving the popularity they have since held, it had its day and was soon forgotten, and one would not wish to revive it except as a reminiscence. It has its suggestions, however, of a theory to account for some of the symptoms of old age that may be not altogether unrelated to the truth, though they are at best merely suggestions and nothing more.

There is hardly any fact that is constantly before our observation, and yet is more incomprehensible than the reality of decay and death. When SIR THOMAS BROWNE described his life as "a miracle of thirty years" he expressed a truth, but not a greater one than was to be that of his death. Why the animal organism under perfectly normal conditions should be steadily on the up grade to a certain point, and from there as steadily on the decline till its final extinction is a question that no one can answer with certainty—we can only speculate. We can assume, it is true, that the vital heredity of the bioplasm, after a certain reproductive period, is transferred to another generation, that the germ plasm only is immortal, while the organism in general, without this invigorating principle or with it undeveloped or exhausted, naturally and gradually tends to its ultimate decline and death.

According to this theory we would expect gradual decay to begin after the cessation of the active reproductive period, and this falls in very readily with certain physiological facts and also with some therapeutic notions that have had a *limited* vogue, such, for example, as the comparatively recent one advanced by BROWN SEQUARD of the benefits from the testicular extract. There are, however, serious objections to the acceptance of the continuity of the germ plasm, and at best it can only be admitted as a rather captivating hypothesis, that may be true but is not a demonstrated scientific fact.

There is another possibility that may be invoked to account for senile decay that is, it is true, partly included in the foregoing, but which may perhaps have sufficient importance to stand alone as a factor. Our existence is a perpetual compromise between the contending influences that tend to growth or decay. Bichat defined life as "the sum of the influences that resist death," and many have since thought it would be hard to improve upon this *rather circular* definition. All our lives we are enveloped in unfavorable conditions, we carry the germs of disease always with us, only waiting for a favorable opportunity, and our system is itself constantly manufacturing and disposing of poisons that are, in themselves, capable of destroying life should by any accident its functions seriously fail in certain important particulars. These functions are constantly becoming disordered, sometimes by external, sometimes by internal agencies, and each time a draft is made upon our stock of vitality. During the period of active growth which in man and some of the higher mammals now covers many years, but which in its origin may have had a close relationship with the cyclic rotation of the seasons, the vital forces, so to speak, are predominant, and the disease germs and toxins can only exceptionally work disaster. When growth is complete the organism is at its best, but is not progressing, and the inevitable tendency is retrogression sooner or later under the steady and continuous attack of hostile agencies. The "microbes" of old age are all the disease germs that attack vitality, either consciously in actual disease or through the slow and by us almost unfelt sapping of the system in a thousand different ways which they must be constantly effecting at every point of least resistance. It may be, as has been conjectured by some, that every form of neoplasm, every morbid state has here and there its germs latent in the organism only waiting, as DR. CLOUSTON has expressed it, for some ebbing of the regulative and resistant cortical energy of the nervous center to leave them free to start on their distinctive career. This recognizes the supreme influence of the brain over vital processes, the control of all functions by the highest nervous center, the cortex of the brain, that formed one of the leading motives in DR. CLOUSTON's valedictory address as President of the Edinburgh Medico-Chirurgical Society, from which the above quoted opinion was taken. Of course the brain suffers with almost every pathologic process and according as its functions are impaired with advancing age the more rapidly do the symptoms of senility appear. But like others of the higher organs its resisting power is the greater, and in the normal course of events the cerebral cortex should be the last to completely succumb to the gradual onset of all the hostile agencies that produce old age. That this is often the case is shown by the numerous septuagenarians and octogenarians who have taken leading parts in the world's progress, and much of the world's best work is done by men past the time when it is generally supposed that brain weight begins to decrease and mentality to be impaired. The truth prob-

ably is that the most of us grow old too fast, that by our own fault or that of our progenitors we yield too soon to the microbes and toxins that hasten on old age

A HOLIDAY HINT TO THE RUSH MONUMENT COMMITTEE

It is the fashion, particularly since the disastrous ending of the China Japan conflict, to hold the Mongolian up to ridicule, and yet, notwithstanding our low estimate of Chinese methods, there is one feature in their economy that our higher civilization would do well to emulate It is a point of honor with the Chinaman of whatever profession or trade to begin the new year with his obligations all met and his balance-sheet squared, so that he is able to look his neighbor in the face clouded by no shadow of debt

Now that the great Christian holiday season which ushers our New Year is approaching, it would be well for us to imitate the Oriental barbarian and see that all our obligations are met One of these, binding upon every medical man in the United States, is the speedy redemption of the long-standing pledge to erect a monument to the great representative patriot physician of the Revolution It must not be forgotten that at the recent meeting of the American Medical Association at Baltimore, every delegate and member there present was by unanimous resolution constituted a member of the Rush Monument Committee, and that it was made his duty to obtain contributions from physicians residing in and about his district for this fund How many of these committeemen have as yet discharged that obligatory duty then imposed upon them and accepted by them? Had these *eight* hundred men collected only ten dollars each, it would have added *eight* thousand dollars to the fund, which would have been sufficient, with the amount in hand, to have erected a monument as appropriate as that to Marion Sims in Bryant Park at New York A very small subscription from the individual members of the profession in their several localities would make it possible for each of these committeemen to return twice that sum, and thus complete the erection of a monument in every way creditable to the profession, since it is no longer the question of a monument but of the kind of monument that will be erected

Shall it be only a $3,000 bust to stand as the measure of the appreciation of the regular medical profession of its immortal exemplar in the same city, and that the Capital of the Nation, with the splendid and costly work of art which the little band of homeopaths in the United States is prepared to erect during the coming year to the memory of their high-priest Hahnemann? Shall it not be at least as imposing and appropriate a testimonial as that which the still smaller body of members of the American Surgical Association is soon to inaugurate also at Washington in commemoration of their distinguished late President, Prof Samuel D Gross, of Philadelphia, or as the members of the profession of Law to its great representative, Chief Justice Marshall, or as the numerous statues to generals and others whose services to this new-born country and to humanity were not a tittle of those of this doctor, who saved men's lived and taught them how to lengthen them, and who offered up his own when he might have rested from his half century of professional work

If, however, it be the fact that the mass of the profession is indifferent or unwilling to subscribe even a half-dollar each to create a fund of $50,000, which some of the equestrian statues of military heroes at Washington have cost, then it is all the more the duty of the few, who have sufficient pride in their profession not to wish it disgraced by invidious comparison, to build *a greater monument than all yet standing* to this medical hero, who was greater than all those they represented Dr Henry D Holton, of Brattleboro, Vt, offered to be one of 100 physicians to subscribe $100 each to this fund, and Dr Wyeth, of New York City, one of six to subscribe $500 each Surely there are five other men in the medical profession in the United States who are able to make Dr Wyeth's offer good, or ninety-nine besides Dr Holton who can write a check for $100 for such a purpose at this Christmas season There ought to be in Dr Rush's native city of Philadelphia alone, where live the men who know his life and labors best—and who have most impressively eulogized him—Weir Mitchell, Pepper, Mills, Musser and a score of others, prosperous medical men—enough to supplement both Dr Holton's and Dr Wyeth's liberal offers Certainly there are twenty great cities in this country which can raise among their leading medical practitioners an aggregate of only $500 each, and if nothing can be expected from a general subscription, we advise the committee to appeal directly to these men for the funds they require to complete the project

It would be a proper recognition of the services of the Rush Monument Committee if its work were brought to an end by the concerted generosity of these few It would be an emphatic, practical expression of their admiration for the man who set the standard of medical worthiness at so high a level It would be a Christmas gift to the whole country to add another testimonial of approval of a life passed in its service to those already adorning its National Capital

The American Medical Association has so often, during the past eleven years, applauded the utterances of the Rush Monument Committee through its Chairman, and has resolved over and over again to complete the work, that it can no longer evade the obligation it has thus assumed, and at the last meeting in such specific terms that we earnestly hope it will like the Oriental merchant, begin the New Year with its account closed to its credit by the fulfillment of its pledged faith

CHRISTMAS, 1895

This issue of our JOURNAL contains some noteworthy contributions The members may indeed congratulate themselves on the value of the original articles herein presented, and that the authors have made the ASSOCIATION a Christmas present of enduring value

The articles of PROFESSORS GOULEY, ANDREWS and KELLY and others have more than a passing interest, and will be referred to again and again with pleasure and profit by all those who bind their JOURNALS

The renewed interest taken in the ASSOCIATION, and the enthusiasm manifested in the great work of enrollment of all the regular physicians of the United States in its membership argue great things in the future Let us not forget the necessity for renewed effort while enjoying the present, and while we listen to the merry Christmas chimes which ring their peal of gladness throughout the land let us determine that in the year 1896 the membership in the ASSOCIATION must be brought to ten thousand

Ten thousand educated regular physicians, united in thought and sentiment although separated by American distances, will become a power for good, the ultimate benefit of which no man can now foresee, but can only dimly comprehend

In union there is not only strength and power, but wisdom

CORRESPONDENCE

Foundation of the Lane Course of Medical Lectures in Cooper Medical College

SAN FRANCISCO, CAL, Dec 8, 1895

To the Editor —The undersigned announces that in accordance with a purpose which he has long entertained he has founded a course of lectures to be annually given in Cooper Medical College and the same to constitute a part of the instruction given in this institution The matter of these lectures shall be some subject within the domain of medical art and science, and they shall be ten or more in number, according to the option of the lecturer The lecturer selected to deliver this course shall be a man of superior eminence in the profession of medicine, and his selection shall be irrespective of nationality The lectures are to be given in the English language and are to remain the property of their author These lectures, when it is practicable to the lecturer, shall be delivered as the initial ones of the semester that begins in June This course shall be known as the Lane Course of Medical Lectures, and the sum of $2 000 shall be paid for each course Financial provision for the perpetual maintenance of this course has been made by the founder The lecturer shall be chosen by the founder during the latter's life-time, and should his wife survive him, the selection is to be made by her during her life time, afterward the lecturer shall be chosen by the members of the Corporation of Cooper Medical College

The friends of Cooper College will be gratified to learn that Dr William Macewen of the University of Glasgow has consented to inaugurate this course in 1896 Dr Macewen states he will be present to deliver these lectures about September 1, 1896

This course of lectures it is believed by the founder, beside adding to the efficiency of the instruction received by the students of Cooper Medical College, will incessantly animate them to industry in their studies through the opportunities which will annually be given them of coming in contact with some of the living leaders in medicine

LEVI COOPER LANE,
Pres Cooper Medical College

Hypnotism and Double Personality

NEW YORK, Dec 16, 1895

To the Editor —I am in doubt whether such a tirade as your correspondent on "Hypnotism" in the last number of the JOURNAL has indulged in deserves notice, for I very much *doubt* whether of the 5,000 or 6,000 intelligent physicians who read the JOURNAL *many* will be found who sympathize with the spirit which it *manifests* Passing by its scurrility, let me say to the readers of the JOURNAL that in these days it is scarcely necessary to discuss the "views" of men who on account of their dense ignorance of the subject have no right to have an opinion, but it *is* necessary to become acquainted with *facts* and to discuss them in a scientific spirit

Judging by the number of letters of inquiry I have received since the appearance of the articles on hypnotism in the JOURNAL of Nov 30, I am sure there are many physicians who are anxious to get at facts, and to know something definite regarding the subject This information can not be given in a letter, but for those who desire a plain, simple statement of the facts and history of hypnotism let me suggest reading "Hypnotism—Its History and Present Development," by Frederick Bjönnstrom, M D, published by the Humboldt Publishing Co, 19 Astor Place, New York, or, if they desire the latest philosophic views and therapeutic uses, get "Suggestive Therapeutics," by Prof F Bernheim, published by G P Putnam's Sons, New York, bearing in mind, however, that his extreme views on the subject of Suggestion are by no means unchallenged by authorities quite equal to himself

Neither can the subject of double personality be discussed in a letter, but I would like to emphasize the statement that the *alleged facts* bearing on the subject presented in the paper which seems to have stirred up the gall of my critic are *real facts*—account for them as we may

It is pleasant to know that my critic, and that of my confrères, since reading that particular number of the JOURNAL has had "reason to modify some of his 'views'" It is to be hoped that he has so modified them The only drawback to that cheerful hope is the difficulty of understanding how a man who has simply sat down in the densest kind of a fog can have *views* of any sort to modify

R OSGOOD MASON

Further Facts Concerning Life Insurance

MUNCIE, IND, Dec 13, 1895

To the Editor —Quite a number of the life insurance companies have banded together and formed an alliance to stop "rebates" In other words they have formed an association to compel themselves to conform to legitimate business principles Some of these companies are known as "racers," *i e*, they pay their agents large sums for securing new business, and these agents, in turn, divide the money with those who can be induced to take out new insurance

To guard themselves against this wrong these companies, now seized with a virtuous impulse, propose to pay a legal referee the sum of $2,000 per year as a salary In addition to this sum he is to be compensated for incidental expenses, and a still further allowance, not exceeding $3,000, for a secretary and clerical assistance!

When we take into consideration the fact that a new officer is to be appointed, and guaranteed $5,000 and incidental expenses besides, does it not look as though this might be one of the microbes that is causing the marked atrophy of medical examiners' fees? Let our microscopists examine this new germ so lately discovered in the insurance kingdom

I am glad to know that some honorable companies spurn such an imputation upon their honor, and refuse to enter into the unholy alliance PHYSICIAN

A Death from Vomiting

WASHINGTON, D C

To the Editor —I notice in your "Philadelphia Notes" of Dec 14 reference to case of death following a violent attack of sneezing The case was reported by Dr Morton at the December meeting of the Academy of Surgery Permit me to briefly relate a case of death from vomiting during an attack of influenza (la grippe) The patient, a man of nearly seventy years, had "dyspepsia" with symptoms of "liver disease," with occasional hematemosis During many years he had taken large quantities of bicarbonate of soda for the relief of so-called dyspepsia During a violent attack of vomiting he felt something "give way," as he expressed it and at once the vomiting ceased The writer could not see the patient for several hours after the vomiting ceased, his condition in the meantime was rapidly growing serious Great pain in the epigastrium extending rapidly over the abdomen Death resulted in eighteen hours from peritonitis At the autopsy an old cicatrix was easily discovered on the lesser curvature of the stomach about two inches from the pylorus The rupture had occurred at this point, with resultant sepsis and peritonitis I S STONE, M D

Concerning the Journal

FROM ONE OF THE OLD TRUSTEES

LITTLE ROCK, ARK, Nov 25, 1895

To the Editor —After reading the proceedings of the Board of Trustees, and your report as editor in the JOURNAL of Nov 23, I feel as if I must send you words of congratulation upon the progress and success you have achieved as manager of the JOURNAL in making it the equal, if not the superior of any other weekly medical journal published in the country It rests now with the members of the ASSOCIATION, and profession generally, to sustain it and maintain it, so that it may become the glory and pride of every reputable physician in the land

With my best wishes for you personally, and for the continued prosperity of the JOURNAL, I remain

Very truly yours, P O HOOPER

SAN FRANCISCO, Dec 8, 1895

To the Editor —The JOURNAL is to be praised for the excellence of its material during the past year

Yours truly, L C LANE

CHICAGO, Dec 11, 1895

I find the JOURNAL to be one of the best among the journals I am now reading R C WILSON, M D

CINCINNATI, OHIO, Dec 7, 1895

I congratulate you on the growth of the JOURNAL under your wise mangement It is easily the leader to day

CHAS A L REED, M D

PUBLIC HEALTH

Contagious Disease Hospital for Newark, N J —The health authorities of that city have been at great trouble to find a location in Irvington for the greatly needed hospital and disinfecting plant for infectious disease prevention and treatment The Board of Trustees for the latter town has concluded to cancel all permissions heretofore granted for the construction of the plant within the limits of that town, and that Board is said to have resisted very promising overtures on the part of the Newark authorities as to the mutual employment of the plant when in working order A part of the trouble seems to have arisen from the fact that the proposed beneficent and up to date institution has been styled a "pest-house" Immediately after that cry had been raised the community of Irvington began to protest as one man

A Sanitary Landmark —The meritorious work of the late Dr Thomas Fanning Wood, for many years the presiding genius of the North Carolina Board of Health, is one of the bright spots in the sanitary history of our Southern States Although Dr Wood passed away in 1892, there are those who keep his memory green In a decidedly out-of the way place, namely, in the columns for book reviews of the *Independent*, the following good point is made The allusion to Dr Wood as the sanitary "John the Baptist" of his State will be appreciated by all good North Carolinians His was the voice of one "crying in the wilderness" for many years The review in the *Independent* has reference to a pamphlet by the successor of Dr Wood in the secretaryship of the State Board, Dr Richard H Lewis, of Raleigh, entitled, "Drinking Water in its Relations to Malarial Diseases" The reviewer says

"This pamphlet, which the Board prints for general distribution, means to one familiar with the history of sanitation in that State far more than its thirty pages indicate It is the index of a great revolution in opinion, and of a general seeking of wisdom's ways that ten years ago would have been deemed impossible There rises up before the mental vision the figure of Dr Wood, the John the Baptist of that State, who paid for the printing of a biennial State Report ten years ago, that he could not afford to "post" back and forth for proof-reading, which was scarcely larger than this single chapter out of the Report for this year He died a true martyr to a noble cause Who says the South is *not* waking up?"

The Migration of the Croton Bug (Ectobia Germanica) —In the last number of *Insect Life*, Mr L O Howard reports upon the perculiarities of migration of certain water-bugs in our Southern cities, whereby new houses are suddenly overrun The following observation was made at Washington, D C One dark and drizzly day, late in 1893, a friend came to me and stated that he had just seen a remarkable sight on D Street, near the Department grounds A vast army of cockroaches, according to his story, was crossing the street A few hours later I visited the spot and found that the bulk of the army had disappeared, but that many stragglers still remained According to the statement made to me, the army issued from the rear of an old restaurant fronting upon Pennsylvania Avenue, and marched across the muddy street, undeterred by pools of water, ash heaps, and other barriers, directly south to the front of the building opposite

This building was a machine shop, and at the direction of the foreman several of the men took brooms and swept back the advancing horde They swept until their arms were tired, but were unable to stem the advancing tide The foreman then directed that a line of hot ashes from the furnace be laid along the brick sidewalk This proved an effective barricade The foremost cockroaches burned their antennæ and their front legs and the army divided to either side and scurried down into the area ways of adjoining buildings in which they disappeared The march is said to have continued for two or three hours and many thousands of the insects crossed in this way A moment's glance, after arriving at the spot showed me that the insect was the croton bug and that nearly all of the individuals were females carrying egg cases

I called at the restaurant and found to my surprise that no house cleaning had been going on, and that no especial effort had been made by the application of insecticides to rid the establishment of the roaches

It seems then to have been a true migration, a development of the true migratory instinct in the croton bug The restaurant had become over populated, perhaps not for its actual denizens, but certainly for the thousands of about-to-be born young The maternal instinct originated the migratory instinct and the army by one common impulse started on its journey for more commodious quarters The darkness of the day is significant, and there is no reason to suppose that similar migrations do not frequently occur but undoubtedly under ordinary circumstances at night This is the way that new houses become infested

Health Reports —The following health reports have been received by the Supervising Surgeon General Marine Hospital Service

NOTE —(Correction is hereby made of a clerical error published in our issue of Dec 14, 1895 The item "Ceara Oct 24 to 31, 2 cases, 2 deaths," should be under the heading "Yellow fever—foreign," not as placed under heading "Cholera—foreign ")

SMALLPOX—UNITED STATES

Arkansas Mississippi Co, Oct 12 to Dec 12, 75 cases, 13 deaths
Arizona Nogales, Dec 9, 3 cases
Lousiana New Orleans, Dec 1 to 7 7 cases, 3 deaths
Michigan Detroit, Nov 23 to Dec 7, 4 cases, 1 death
Ohio East Liverpool, Dec 14 1 case, Bridgeport and vicinity, Dec 14, 18 cases, Martin's Ferry, Dec 14, 22 cases,
Pennsylvania Philadelphia, Oct 1 to Dec 12, 2 cases

SMALLPOX—FOREIGN

Antwerp, Nov 20 to 27, 1 death
Barcelona, Oct 1 to 31, 12 deaths
Buda Pesth, Nov 18 to 28, 2 cases
Constantinople, Aug 1 to 31, 14 deaths
Dublin, Nov 27 to 30, 2 cases
Glasgow, Nov 23, to 30 3 cases
London, Eng, Nov 27 to 30, 1 death
Manchester, Nov 16 to 23, 1 case
Naples, Nov 9 to 16, 7 cases, 7 deaths
Odessa, Nov 16 to 23, 2 cases, 1 death
Prague, Nov 16 to 23, 12 cases
Rotterdam, Nov 28 to 30 2 cases
Warsaw, Nov 9 to 16 1 death
St Petersburg, Nov 16 to 23, 6 cases, 1 death

CHOLERA—FOREIGN

India Bombay, Nov 5 to 12, 14 deaths, Calcutta, Oct 26 to Nov 2, 29 deaths
Austria Hungary, Nov 6 to 18, 47 cases 39 deaths, (from Aug 23, date of outbreak to Nov 18, 350 cases, 234 deaths
Russia Volhynia, Sept 29 to Oct 12, 2,901 cases, 1 190 deaths, Kiev, Sept 29 to Oct 12, 59 cases, 37 deaths, Rustengebiet (Siberia), Oct 2 to 15, 4 cases, 1 death

YELLOW FEVER—FOREIGN

Cuba Cienfuegos, Dec 1 to 8, 2 deaths
Puerto Rico San Juan, Nov 22 to 29, 115 cases, 19 deaths

SELECTIONS

Vesical Hernia.—The patient, age 56 years, had a protrusion in the right inguinal region as large as a plum, soft, tympanitic, completely reducible An operation was desired and disclosed a lipoma on the innerside of a hernial sac, and attached to the lipoma a diverticulum of the bladder, only recognized by the flow of urine following incision The bladder had penetrated the aponeurosis, making a direct hernia, while the hernial sac noted by the side of lipoma was indirect The vesical incision was closed and Kocher's radical operation carried out Recovery without complication —*Münchener Medicinische Wochenschrift*, 1893, No 32

Variations in Immunizing Power of Serum from the Horse —Ceni has reported to the Medico Surgical Society of Pavia his experiments to determine the fluctuations in the antidiphtheritic immunizing power of the blood-serum of horses in consequence of muscular exertion So long as the muscular activity is not injurious to the system there is no reduction, rather a slight increase, but over taxing work, which is accompanied with reduction of body weight, greatly influences the immunizing power For example, a horse which yielded serum of 80 units strength after twenty-five days of hard labor causing loss of 90 kilograms in weight, furnished serum of only 20 units strength —*Wiener Klinische Rundschau*, Sept 1, 1895

The Changes in the Thyroid Gland in Exophthalmic Goitre —Lubarsch (*Centralbl für Allg Path u Path Anat*, Bd vi, No 15) examined a number of thyroid glands in exophthalmic goitre and found certain quite constant changes, among which the following are the more important 1, In these thyroids he found only rarely real gland follicles, mostly there were present dilated spaces clothed with epithelium in which more or less marked papillary formations were observed, 2, these spaces contained but little or no colloid material, but, 3, a fluid of mucoid appearance In regard to the pathogenesis of exophthalmic goitre, Lubarsch expresses the opinion that the changes in the thyroid gland are not secondary and not due to primary changes in the sympathetic or the medulla oblongata, as has been advanced by some writers Hypersection of colloid material can not be regarded as the cause, because the enlarged thyroid in this disease does not secrete much if any colloid substance In all probability it concerns an unknown etiologic factor which brings forth the changes observed in the nervous system as well as those in the thyroid gland

The Post Mortem Findings in 180 Suicides —Heller (*Centralbl fur Allg Path u Path Anat*, Bd vi, No 18) describes the postmortem findings in 180 instances of suicide observed in Kiel The ages varied from 9 to 82 years It was found that 20 6 per cent committed suicide by shooting Statistics show that in Prussia 13 3 per cent of the suicides shot themselves and the larger percentage of this mode of suicide in Kiel is explained as due to the presence of so many soldiers Concerning the anatomic changes which would allow some deductions as regards responsibility, the following may be stated In 10 4 per cent there were no changes in the brain which would allow the inference that there had been any disturbance of the brain functions, in 6 per cent there was some changes, in 9 9 per cent marked changes, as, for instance, chronic leptomeningitis, pointing in direction of psychic alterations In 48 4 per cent there were very marked cerebral changes which would militate against the theory of responsibility for the act of suicide, and among these were numerous alcoholics Six per cent were insane In 19 3 per cent there was present either acute febrile disease, menstruation or pregnancy in women

Contribution to the Pathologic Anatomy of Puerperal Eclampsia. —Luesden (*Virchow's Arch*, Bd CXLII, Heft 1) examined exhaustively two fatal cases of puerperal eclampsia and summarizes his observations and conclusions in regard to the pathologic anatomy as follows 1 The two cases afforded no evidence whatever of an infectious or bacterial origin of the eclampsia 2 The cause of eclampsia seems to be some toxic substance circulating in the blood 3 The organic changes that merit the first consideration in eclampsia are the renal affections (In both of Leusden's cases there was a well marked nephritis) 4 Multinucleated cells, first found in the lungs by Schmorl, were presented in both these cases, and such cells correspond fully with the so-called giant cells of the placenta 5 The presence of these cells is simply an accidental occurrence 6 It has not been possible to demonstrate that these cells have any power to cause the formation of fibrin 7 The development of other substances in the placenta capable of causing fibrin formation could not be proven in either of the two cases 8 Embolism of liver cells was not found in either of these two cases 9 Limited necrosis of the hepatic parenchyma was present in both cases, but this *could not be regarded as the cause of the eclampsia* 10 The hyaline thrombi in the capillaries of the lungs and the liver were presumable secondary changes, and these thromboses are not peculiar to eclampsia 11 The hyaline thrombi in the lungs are looked upon as of close relation to *the development of the acute pulmonary edema*

New Anatomic Nomenclature —The new anatomic nomenclature referred to in these columns recently, seems to have met with strong opposition in one quarter Prof Dr R Kossmaun, of Berlin, while he welcomes the attempt to harmonize designations in anatomy, yet feels himself called upon to point out in the *Deutsche Medicinische Wochenscrift* many imperfections, some of which, at least, might have been easily avoided His points of issue are, the question of accentuation, the etymologic correctness as Latin terms, and the hybrid composition of some of the designations The Commission decided at Munich to indicate by an accent the proper pronunciation We can all realize how easily a slip is made by a careless lecturer, and repeated and carried out by students, but we can hardly conceive the need of correction so great in this country, as is indicated by a quotation in Professor Kossmaun's article, to wit "*Nos Pôloni non curamus quantítatem syllábarum*" The excuses of the Commission for this change in plan are poor, and it remains a defect Under the second head is noted the false Latinization of the Greek eidos, for instance, ziphoidens instead of ziphoides, os ethmoidale instead of os ethmoides In ethmoidalis we see a Latin termination applied to a Greek stem Mesovarium lymphoglandula and epitrochleoanconeus are instances of hybrid words, the last named starting with a Greek stem followed by a Latin, and terminating in a second Greek The critic would also banish fibrocartilage, mentolabialis, oculomotorius, in favor of fibricartilage, mentilabialis and oculimotorius, in correspondence to classic instead of late Latin models He notes also the use of gastroepiploicus, instead of gastrepiploicus, parotideomassetericus for parotidomassetericus By other instances, also, we see that our anatomic terms are often not formed on classic models, and that much thought must be given to the subject before we arrive at a correct anatomic nomenclature

Influenza and Encephalitis —Nauwerck (*Deutsche Med Wochenschr*, 1895, No 25) had the opportunity to examine, bacteriologically, two fatal cases of influenza-encephalitis The first case was that of a girl who became ill with brain symptoms one week after an attack of influenza, and died after seven days There were found several foci of softening and venous thrombosis in the cerebrum, but the bacteriologic examination was negative In the second case, a young woman presented violent symptoms of brain inflammation preceded by coryza and pains in the joints, death ensuing on the third day On opening the cranial cavity the convolutions were found flattened, and on incising the bulging corpus callosum 50 ccm of turbid watery fluid flowed out In the right cerebellar hemisphere was a walnut-sized apoplectic area with grayish-red softened walls Inoculations on blood-serum agar with the ventricular fluid resulted in a growth *on* but *one* tribe In this tribe there developed in the incubation a delicate, transparent, granular culture which consisted of very small bacilli without capsules and diplobacilli with rounded ends Compared with Pfeiffer's photographs they appeared somewhat larger than, but shaped much like, the influenza bacilli *Reinoculation failed to* produce further growth Cover-glass preparations from the ventricular fluid showed these bacilli to be the only microorganisms present These bacilli were also found in sections from the hemorrhagic focus in the cerebellum, although in but small numbers Nauwerck concludes that they were influenza bacilli, and that the cerebral disease was due to these microorganisms only In the first case, in which the bacteriologic examination was negative, it is asumed that the bacilli had already died at the time of the post-mortem The bacilli are thought to have reached the *brain* by way of the blood

The Buried Tendon Suture —At the recent meeting of the Southern Surgical and Gynecological Association, held in Washington, Dr Marcy, of Boston, read an interesting and instructive paper upon the history of the buried animal suture and the best methods of its preservation and use Since he was the first to suggest the employment of buried sutures and demonstrate their value, his contributions upon this subject are of more than ordinary importance His first contribution upon the buried catgut suture was published in 1870 In 1880 he substituted tendon for catgut, as in every way superior, and in various articles he has called the attention of the profession to the importance of its general adoption

Dr Marcy stated that the defect of catgut is inherent in its structure, and that it can not be rendered satisfactory by any method of preparation "The connective tissue sheath from the intestine of the sheep, from which catgut is manufactured, has its ultimate fibers disposed in an oblique direction, crossing one another diagonally This serves the physiologic purpose of permitting foreshortening and distension as well as strength" The violin string, catgut of commerce, is not unlike a very thin piece of tissue silk which has been cut diagonally and then twisted This would make a very imperfect fish line, and Dr Marcy thinks the comparison not overdrawn When dry *the gut is strong, but when* wet is flat, elastic and slippery, a state which necessarily pertains after implantation in the tissues Chromicised tanning only partially remedies this defect and sterilization by any process can not correct the damage which the inter*cellular cement substance has sustained from the bacterial* infection and maceration process to which, in preparation, the catgut is necessarily subjected

Properly prepared tendon not only escapes these injuries, but has an entirely different ultimate construction The *connective tissue cells are disposed parallel to each other*, and are the strongest structures of the animal economy of equal weight, carefully selected tendon will sustain a tension equal to that of silver wire Tendons taken from the freshly killed animals are quickly sundried and kept dry until their *first preparation Soaked in a 1 to 1,000 mercuric solution* until supple, the tendons are carefully cleaned, assorted and dried between sterilized towels They are then chromicised until of a dark golden yellow, and preserved in sterilized linseed oil to which one-tenth part of the crystals of carbolic acid *has been added Sutures thus prepared improve by* age When desired for use, they are soaked in 1 to 1 000 solution of bichlorid of mercury until supple Preserved in absolute alcohol, boiled in it under pressure, boiled in kummel (oil of carroway seed), indeed, prepared by any other of *the many ways suggested for the sterilization of catgut*, serve only to injure the inherent structure of tendon and are not to be commended The tendons from the tail of the smaller varieties of the kangaroo furnish by far the most valuable suture material yet found The anatomic construction of *the psoa muscles of the rat, squirrel and opossum is not un*like that of the kangaroo, each fassiculus having its independent tendon extending the entire length of the tail The tendons of these smaller animals are too short and fine, those from the large kangaroo too large The latter, when subdivided, fray and are less *valuable Dr Marcy reported that* from various sources, kangaroo tendons have recently been put upon the market which are very defective One lot of three hundred pounds, collected for him, was almost entirely from the large kangaroo, and so undesirable that he refused *its acceptance This at a price, has found its way into the* American market and is being distributed to the profession Selected tendon should be furnished at $10 per hundred, although usually sold at a much higher price Dr Marcy has secured reliable parties who prepare the tendon subject to his supervision, and it may be *obtained at this price by* addressing him

Dr Marcy closed his paper with an account of his many histologic experiments upon animals and of his large surgical experience He expressed the belief that all aseptic wounds including *even the larger amputations*, should be closed in layers by the buried tendon suture without drainage The edges of the skin are coaptated by means of a parallel continuous buried suture (subcuticular), and the wound is sealed with iodoform collodion, strengthened by a few fibers of cotton The advantages of the buried tendon suture are briefly as follows *Aseptic*, buried in *aseptic* wounds they remain *aseptic* the repair is primary without inflammation, pain or suppuration, the iodoform collodion seal renders subsequent infection impossible, no sutures are to be removed, and no other dressing is required the tendon is absorbed so slowly that it may be traced months after implantation, ultimately it is replaced by a band of vitalized connective tissue which serves as a permanent reinforcement to the united structures

Tuberculosis in the Yellow Race—Dr Ernest Martin, of the French Legation in China, has just published an important work on this subject, from which is taken the following

The population, composed of what ethnography designates under the name of *Yellow Race*, forms in itself a third of the whole population of the globe The two important questions to study in this connection are 1 Does tuberculosis exist in this race? 2 At what period did it appear there?

Chinese medical works describe a disease called *lao ping*, which means a disease which seats itself in the lungs, and, spreading throughout the system, consumes like fire The writings of European doctors who have practiced among this people furnish more explicit reports Rennie, in the course of an extended practice at the hospital of Tam Soui, the most important and populous city of the island of Formosa, treated 22,000 different disorders, among which the different forms of tuberculosis appear for only 1 25 per cent M Geurin, surgeon in the French army, who has passed three years among the Formosans, reports that they are endowed with a strong constitution, which makes athletes of them, and that there is very little consumption among them According to the statistics of M Dudgeon, physician of the dispensary of Pekin, which is maintained by the Evangelical Society of London, out of a total of 3,157 diseases treated in 1865, tuberculosis was mentioned only 36 times M E Britschneider who for twenty years has held the position of doctor to the Russian Legation at Pekin, declares tuberculosis much less frequent in that city than in St Peterburg The personal experiences of M Ernest Martin, covering several years and gained principally at the Orphanage of Gen-Tse-Tang, at Pekin, have furnished him with similar proofs He writes ‘Consumption is very infrequent there, even among the most wretched class of people, notwithstanding the fact that the public hygiene of the capital leaves much to be desired Having therefore proved the infrequency of tuberculosis in the Yellow Race as compared with the nations of Europe, let us find out the causes Let us study into the state of society, the public institutions and hygiene, and see if they can throw any light on the subject The density of the population of China surpasses nearly all other countries in the world The cities are closely packed, but their population is not equal to the large cities of the civilized world Tien sin counts about 950,000 Fou-Schow 630,000, and Canton 1,600,000, the largest population unless we consider Han-Keon and Han Yang as a single center, the population of which would be about 3,000,000 In none of these cities do we find such crowded quarters as certain localities in Paris, where they count 3,000 persons to a hectare

“As there are no great industries in China, we do not find the accompanying evils of large factories and crowded tenements Barracks are done away with entirely There is no standing army in China There are thousands of Tartars, soldiers of the Imperial standards, but they live with their families Although a nation counting at least 400,000,000 souls, it might be said that she has no army in the European sense of this word According to the latest statistics concerning consumption in the French army, it would appear that 40 per cent of the cases were contracted in the army Here, then, is one source of contagion not found among the Chinese

‘Extended imprisonment is another source to consider It is true the Chinese prisons are foul dens, with no attempt for hygiene, but while their laws are strict, they do not misuse this form of punishment Penalty of death, exile, the bamboo, and the cangue are most often inflicted The first of these does not permit of a long imprisonment, exile does not bring on consumption, the blows of the bamboo are quickly dealt, and as for the cangue the condemned generally carries it without being imprisoned—he has his liberty and goes about wherever he chooses Nevertheless, public hygiene is almost wholly neglected in China The inundations due to the falling away of the land and to neglect of public works are the source of continuous and deadly epidemics

The capital itself is no exception It is an object of disgust to strangers The sewers, which date from the fifteenth century, have been out of repair for some time, and have become the receptacle of all the débris and the source of the typhoid epidemic which reaps large harvests yearly The wealthy, living in their great yamens, are less exposed to it, as are also the foreign residents, thanks to their good hygiene, and more than all to their exodus into the neighboring hills during the torrid heat of summer Such is the state of affairs in Pekin, and the other cities of the empire are no better in sanitary matters It is not, therefore, in the city masses which, although not as closely packed as those of Europe, are also less numerous, but where, on the other hand, hygiene is scarcely regarded at all that we must seek for the explanation of the infrequency of tuberculosis”

In considering the question of personal hygiene, and especially of alimentary hygiene, Dr Martin finds no positive evidence to help in explaining the situation of things Alcoholism, which in Europe constitutes a powerful factor in tuberculosis, scarcely exists among the Chinese They are sober, and sober they remain at all points of the globe where their emigration reaches They smoke opium, it is true, but, though millions of them are addicted to this habit, it is very seldom that they go so far as to undermine the constitution and suffer in consequence the same fate as drunkards—that is, to become consumptives

The chapter devoted to the biological and ethnic peculiarities of the race, which throws some light on the subject, is full of interest and the result of careful research In connection with the domestic life of the Chinese, Dr Martin mentions the fact no animal milk is ever used in feeding infants Maternal nursing is the rule, hired nurses the exception, and artificial feeding quite unknown The life of the woman is necessarily quiet Her time is passed almost entirely in her own apartments, which she quits only to make visits of ceremony or to go to the temples and family tombs The mutilation of the feet, inflicted upon the Chinese woman, is not without its injurious effects, and does indeed seriously impair the health of a large number of children This custom is, however, strictly carried out only among the higher classes As the nature of the Chinaman is passive to a remarable degree, he rarely experiences those great shocks from which it is so difficult for others to recover We give in full the concluding remarks of this important work

“In a word, then, the yellow race is, although not wholly free from tuberculosis, comparatively so as compared with the other races of the world We credit this infrequency of the disease, and the comparative immunity, to certain social and ethnic conditions And are these conditions liable to change? Will not the emigration of this people to so many different points of the globe, particularly to the New World, bring about such a result? For, although many of them remain permanently in strange lands without any hope of returning, the majority eventually go back to their native land, carrying with them to a great extent, the morals and customs of the countries of their temporary exile On the other hand, there are many foreign residents in China, and the natives are quick in imitating whatever evil example the former may set The opium habit which is increasing daily is an illustration of this fact However strong, up to the present day, may have been the resistance of this people against all innovations which Europe has attempted to introduce, the day will undoubtedly come when the advance will be sounded and then a decided change in the social state of the country will place her in such condition that she must fatally undergo the evil results of civilization, one of the most certain evidences of which is tuberculosis—*Journal d' Hygiene, Paris*

SOCIETY NEWS

Chicago Ophthalmological and Otological Society—Regular meeting, held Nov 12, 1895, at 155 Dearborn Street, F C Hotz, M D, in the Chair

There were twenty two members and visitors in attendance

Minutes of the last meeting were read and approved

The Secretary read the applications of Drs E T Dickermann, of Chicago, and C M Robertson, of Davenport, Iowa

The applications were referred to the Committee on Membership

Dr Hale showed a young man of 19, whose vision had always been bad O S, v c—20 = 3-200, v being eccentric

O D, v c — 20 = 5 20 There were well-marked choroidal changes in both eyes, central in O S

Dr Hale wished to know if the members were in favor of removing the lenses in such a case?

Dr Tilley thought that, in general, such an operation would be justifiable

Dr Coleman had a case where he needled the lens, which was slightly cataractous Before the operation a minus 20 was needed to give the best vision Three operations were done After the first one there was some pain, but not after the second and third There was only slight improvement in consequence of the operation, but the vitreous was full of opacities which interfered

Dr Coleman thought it unwise to ever extract the lens in such cases, needling being the only operation

Dr Wilder spoke of the dangers of starting up a quiescent inflammation by any such operative procedure On the whole, however, he thought the risks were justifiable

Dr Holmes thought the fundus changes contraindicated operation as a rule

Dr Hale then spoke of the clinic at Kiel, and referred to the uniform kindness and courtesy of Prof Voelckers The University of Kiel is a small one, but the buildings are modern and the eye clinic, especially, is very complete The general operating room he considers one of the best in Europe Prof Voelckers is a very energetic and charming man He was a favorite pupil of Donders and a fellow student of Knapp, of New York

While the great ship canal was being built, the clinic was much increased by the workmen, who suffered greatly from conjunctival diseases, especially trachoma

Methods of treatment of various diseases of the eye were described at length Refraction is very poorly done according to American ideas, almost no cylinders are used Voelckers is a beautiful operator He does advancement for squint, iridectomies in cataract operations, and prefers enucleations to eviscerations

Dr Wilder then read a paper entitled "Pulsating Exophthalmus" (This paper will be published)

Dr Gradle had seen a case of vascular tumor of the side and floor of the nose which was slowly removed in twenty operations, this large number of operations being required on account of severe hemorrhages, and only a little being done at a time Three weeks after the tumor had been entirely removed there was diplopia due to interference by pressure of the same side with proptosis, but no pulsation This disappeared however, in three months

Dr Coleman showed a new milliampèremeter by Schulmeister

The Society then adjourned by limitation

Annual Meeting of the Marion County Medical Society —At the annual meeting of the Marion County (Fla) Medical Society the following officers were elected for the ensuing year President, W V Newsom, First Vice-President, D A Smith, Second Vice-President, T J Myers, Secretary, R P Izlar, Treasurer, W R O Veal On motion the following resolutions were adopted

Whereas, The various life insurance companies throughout the United States have reduced the fee for medical examinations from $5 to $3,

Resolved, That the members of the Marion County Medical Society refuse to make such examinations for less than $5

Resolved, That this preamble and resolutions be spread upon the minutes of the society and published in the medical press of the United States

Also the following which was carried

Whereas, This society believes that a Department of Public Health under control of a secretary, who should be a member of the cabinet of the President of the United States, is necessary to the welfare of this country therefore, be it

Resolved, That the society indorses the bill now pending to establish such Public Health Department, and requests our members of Congress to support said bill and aid in its passage

Resolved, That the secretary be requested to transmit a copy of the foregoing preamble and resolutions to our senators and representatives in Congress

Resolved, That this preamble and resolutions be spread upon the minutes of the society

Dr W V Newsom, as president, delivered his annual address to the society on the "History of Medicine," and responses to calls were made by Messrs Reardon, Bullock, Bittinger, Anderson, Brumby and Izlar Rev Dr Law invoked the blessing and protection of the Deity

NECROLOGY

F P Porcher, M D, the eminent physician and professor, died at Charleston, S C, on Nov 19, at the age of 70 He was a South Carolinian by birth, of Hugenot extraction He took his A B and M D degrees from his home colleges, the latter in the year 1847 He served as surgeon in the Confederate Hospitals of Petersburg and Norfolk, was President of the State Medical Society and visiting physician to the Charleston City Hospital He was professor of materia medica and therapeutics in the Medical College in the State of South Carolina, and was the author of works on pharmaceutical botany His "Resources of the Southern Fields and Forests" reached two editions, those of 1863 and 1869, the former being a book of over six hundred pages His contributions to medical literature were varied and instructive

F L Bond, M D, of Menominee, Mich, Dec 3——C E Edwin, M D, of Kansas City Mo, Dec 7——L B Perry, M D, of Winamac, Ind, Dec 11, aged 43——Elias Jessup, M D, of Whittier, Cal, Dec 3, aged 62——William B Porter, M D, of Chicago, Dec 12——H C Garner, M D, of Kansas City, Mo Dec 10——Levi Keehn, M D, of Syracuse, N Y, killed by a railroad train, Dec 10——M B Folwell, M D, of Buffalo, N Y, Dec 10, aged 54——A J Hobart, M D of Clinton, Iowa, Dec 6, aged 70 ——Thomas Cox, M D, of Marietta, Ohio, Dec 10

MISCELLANY

International Congress of Thalassotherapy —The French Association for the Advancement of Science will hold its next session in Tunis in April, 1896, and on that account the International Congress of Thalassotherapy will be held at the same time and place

Semi-Centenary of the Discovery of Anesthesia —According to *Nouveau Remèdes*, the Medical Press Association of France is engaged on the proposition of its Secretary General to celebrate in some way next year the semi centenary of the discovery of anesthesia (Sept 30, 1846) A committee consisting of Messrs Cornil, Lucas-Championniere and Beaudouin has been designated to prepare the program

Chicago College of Physicians and Surgeons —A press dispatch dated Champaign, Ill Dec 10, imparts the following Five representatives of the Chicago College of Physicians and Surgeons arrived in town this evening to confer with the Board of Trustees of the University of Illinois regarding the annexation of the medical school to the university This project has been under discussion the last two years by stockholders of the College of Physicians and Surgeons

Without Fear —Dr Belman, a well-known Suffolk doctor, had a great contempt for homeopathy An old lady who pinned her faith to Hahnemann, one day took five globules by mistake for three, and, her own doctor being absent, Dr Belman was sent for post-haste He came, looked grave, shook his head and said if people would meddle with dangerous drugs they must take the consequences "But, madam" he added, "I will die with you," and lifting the bottle of globules to his mouth, he swallowed its entire contents —*Salt Lake Tribune*

The Red Cross in Cuba —The medical men of the United States have made their influence felt in respect of the Red Cross on nearly every battle-field of the world Cuba is the field at the present time Red Cross work in that country is being conducted by an American missionary there, Dr A J Diaz The New York *Independent* has learned that he has organized and located seven Red Cross hospitals in the section where the fighting is most frequent and where the Spanish Government has about twenty thousand soldiers At each station there are a native physician, two women nurses and about ten male helpers The Spanish Government officials have given formal recognition of their satisfaction in this humane work

The Medical Staff of the Fire Department of New York City —The Fire Commissioners have lately voted to make a radical change in the staff of surgeons serving that Board The following named physicians have been removed Drs Frank L Ives, Robert A Joyce, John J Quigley and James A Mc Laughlin The new appointees are Drs Fred A Lyons, Edwin B Ramsdell and Francis M Banta It was decided that the Department would hereafter require three physicians instead of four The new appointees were chosen from the civil service list and began their duties Dec 1 The salary of these surgeons is $2,000 per year The Commissioners alleged that they removed the surgeons named, or some of them, for cause It is possible that the two junior removed surgeons will resist the action of the Commissioners by lawsuit They were duly appointed from the civil service list

A Medical Explorer —The medical profession has yielded several explorers Their names are enrolled among those who have helped to rescue Central Africa from barbarism Emin Pasha and Dr Parke will not soon be forgotten Among the feats which had hitherto baffled the efforts of the most intrepid travelers was the exploration of Lake Rudolf Thomson and Gregory both tried to reach the lake from Masailand, but were defeated in their endeavors by the hostility of the native tribes and the dangers of the climate A young American medical man, Dr Donaldson Smith, has however, succeeded in reaching Lake Rudolf from the north through Somaliland He is thus the first white man who has visited this *terra incognita*, and geographers are looking forward with interest to the publication of his records and diaries Dr Smith was in Somaliland on a sporting expedition and hearing that no white man had ever penetrated to Lake Rudolf from the north he determined to make the attempt He came to England and made preparations for this serious and dangerous expedition He left London last May, and took with him Mr Gillett, a taxidermist, and Mr E Dodson The former was obliged to return home It has always been believed that Lake Rudolf lay in the midst of a fertile country rich in ivory, but peopled by implacable and hostile tribes We congratulate our medical colleague on being the first to bring light into this dark continent —*British Medical Journal*, Nov 23

The Gold Headed Cane and Other Mannerisms are now Happily Defunct —According to a writer in *Lippincott's Magazine*, a great gain has been made in and for the profession of medicine by the shelving of its distinctive marks of attire and demeanor He says

"A very gratifying tendency has marked the development of the medical profession in the last generation The slough of manerism, the formal dress, the owl-like solemnity have been thrown off, and the physician, by his own choice, is being judged more by his actual attainments than by external appearances Thirty years ago, a bald head, a white beard and a long frock coat were as much a part of the physician's equipment as his diploma Now, on the other hand it is no infrequent occurrence for an elderly man of real ability and modern in his methods of practice, to lose a patient through the fear that he may not be fully abreast of the times What can be further from the old traditions than a leading surgeon lounging about in an outing shirt and blue belt, or a distinguished physician playing polo? Yet these amusements are simply a relaxation from the tension of professional study One of the best indications that people are learning to judge their medical advisors by their merits is the fact that the advertising physicians are being driven to the wall, despite the most specious extrinsic evidences of success that the shrewdest business methods can produce"

Traumatic Mastitis in Men —At a late séance of the Paris Academy of Medicine, M Auguet reported the case of a carter 23 years old, in good health, without tuberculous or syphilitic antecedents, who received a violent blow in the right breast by being struck by his horse's head The force of the blow knocked him down, and he lay unconscious a few seconds, upon rising he felt no inconvenience save slight pain over the contused area, and was able to continue the journey That night, however, the pain prevented rest, it was of a neuralgic character, shooting to the shoulders and arm, and the following morning he sought medical advice Upon examination the right pectoral region was found to be swollen and hot, around the nipple was a swollen area in the mammary gland involving the upper and external lobes, the gland was the size of a hen's egg, it was painful, mobile, there was no echymosis nor osseous lesions Treatment consisted of wet compresses, then, the inflammation having subsided by frictions with Neapolitan ointment, cupping and compression of the breast In a month the cure was complete but the gland while having a normal consistence remained enlarged It has continued to increase in size until at present, a year after the accident, it forms a considerable prominence The submammary groove is obliterated, the nipple is pushed down and in, and the lobes of the gland can be felt distinctly through the skin, The swelling extends 10 centimeters above the nipple, 12 below, 8 to the outer side and 4 to the inner It is troublesome by reason of its size, so much so that ablation seems indicated, but it is absolutely painless and there seems to be no morbid change in the glandular tissue Consequently we have to deal with a simple hypertrophy of the breast, following traumatic mastitis —*Le Bulletin Medicale* 1895 No 78

Sufficiency of Charge of Practicing Medicine Without License —By the act of the Legislature of 1891 to establish a State Board of Health and regulate the practice of medicine in the State of Nebraska, it was made unlawful for any person to practice medicine, surgery or obstetrics, or any of the branches thereof, without first having obtained and registered a certificate from the State Board of Health as provided in the act Certain exceptions were made by Section 11 of the act, but were not from the operation of the portion of the law which required a certificate to be obtained from the State Board of Health, and its registration by persons practicing medicine, surgery or obstetrics After the expiration of six months from the passage of the act, the persons designated in the exceptions were as liable to prosecution for non compliance with the law in these particulars, as any others Consequently, the Supreme Court of Nebraska holds, in the case of O'Connor v State, decided Oct 15, 1895, that as the subject of the exceptions did not become a part of the description of the offense of non compliance with the provisions of the act or limit or qualify the language of the act creating such offense, no negative averment in regard to the exceptions is necessary in an information charging a person with practicing medicine after the six months has elapsed, etc , without having complied with the provisions of the act In this, the court overrules a former decision to the effect that a negative averment in regard to the matter of the exceptions was necessary in an information of that character The statement in the statute that "any person shall be regarded as practicing medicine within the meaning of this act, who shall operate or profess to heal or prescribe for or otherwise treat any physical or mental ailment of another," the court further holds, is a definition of practicing medicine, and that, in charging the crime of practicing medicine without having complied with the provisions of the act, there must be a statement of facts showing the doing by the accused person of one or more of the acts included within the foregoing statutory definition

Bacteriologic Examination of the Blood in Typhoid —Dr Martin Thiemich discusses this question on its practical side The attempts to find the bacilli in the feces are far from being always successful, and latterly the differential diagnosis between the typhoid bacillus and non-pathogenic intestinal bacteria is found to be attended with extreme difficulty By puncture of spleen during life, however, the bacteria is obtained in most cases, and in blood from a rose spot the positive results have out numbered the negative, and the identification of the bacillus is easier from both of these sources A resumé of the results of different investigators is given, followed by his own in seven cases Every precaution was taken in his cases to avoid contamination So far as known, there is no one characteristic of the bacillus of typhoid, obtained through the microscope or by cultivation, which alone will distinguish it from other microbes, but there must be an assemblage of points The diagnosis was regarded assured in the 7 cases reported, when the typical invisible growth was present on potatoes, when no gas formed in either case, milk, or grape-sugar agar When milk was not coagulated, the indol reaction was negative and gelatin plates showed no vine-leaf veining In the seven reported cases, typhoid bacilli were found from rose spots in three (no rose spots present in one case), and from blood from a vein in a fourth In the three fatal cases bacilli were found, after post-mortem, in the spleen, also in one in the lung with Fraenkel's pneumococcus in pneumonic foci, and in one case in the mesenteric glands with staphylococci In the fourteen cultures from blood staphylococci developed six times, whether from contamination or their presence in the blood could not be decided —*Deutsche Medicinische Wochenschrift*, Aug 22, 1895

Practical Notes

Chlorohydrate of [Pilocarpin —During the epidemical grippe this year in the village of Plancher-les-Mines and its vicinity, M Poulet had occasion to test the usage of chlorohydrate of pilocarpin on 108 patients suffering from grippe and pneumonia He administered the salt in a daily quantity of 05 centigr , the treatment lasted usually two days, rarely three days Out of the 108 cases, there were only 4 deaths —*Revue Internationale*

Local Treatment of Neuralgia —(SABBATANI)

℞	Menthol	
	Guaiacol āā	1
	Alcohol, absolute	18

M S Gentle friction with the aid of a pencil to the painful parts, with 4 grams of this mass The parts are then covered with wadding The dressing may be repeated two or three times in twenty-four hours —*Ther Wochenschrift*, 1895, No 35, and *Nouveau Remedes*

Cure of Prostatic Hypertrophy by Section and Ligature of the Vas Deferens—The priority of the idea of the employment of castration for prostatic hypertrophy belongs to Launois This operation has been put in practice and tested by Ramm, White, Broome, Haynes and Mouillin, but castration is not always readily accepted , it has, moreover, a certain degree of gravity Deja Bier, in 1894, proposed the ligation of the internal iliac arteries, with the idea of causing atrophy of the prostate Isnardi recommends a simpler operation, and one that is a perfect substitute for castration, which has all the advantages, without the inconveniences, namely Section and ligation of the deferent canals He has employed this method twice , the first case is conclusive , a cachectic old man, suffering from visceral cancer, which carried him off in two months The second case is very instructive , a man aged 72 years, suffering from retention and incontinence, due to prostatic hypertrophy Left testicle atrophied in consequence of blennorrhagia epididymis The rectal touch revealed on the right side a large tumor like the half of a nut, while the left side showed none Operation, May 1, 1895 , section of the right vas deferens between two ligatures Patient recovered from his urinary troubles, the prostate diminished in volume, and the right testicle became atrophied like the left —Isnardi, *Gazzette di Torino*, No 31, 1895

Pulmonary Surgery —In a discussion which took place in the *Société de Chirurgie* (Nov 20, 1895) M Ricard related an operation in which he had exsected a portion of the eighth rib, incised the pleura and then with a thermo cautere incised the lung to a depth of seven centimeters The incision was made toward the center at the level of the opening. MM Dienlafoy and Giraudeau had previously examined the patient and located the abscess opposite the inferior angle of the scapula When M Ricard had passed the thermo-cautere into the lung to the depth mentioned, he then passed in his finger for further exploration He felt an induration toward the mediastinum near the diaphragm. He was satisfied from the touch that an abscess existed, and he passed a trocar along his finger and punctured the mass Pus followed, the cavity was drained and the patient recovered M Ricard concludes from the case that in deep pulmonary suppuration neither percussion, auscultation nor exploratory puncture are sufficient to invariably determine the seat of the lesions He believed it necessary to open the pleura and pulmonary tissue, and he therefore was of opinion that the method of M Tuffier of detaching the parietal leaf of the pleura, would add to the natural difficulty

M Tuffier in reply reaffirmed his view that the detachment of the pleura allowed the finger to transverse the entire lung surface, and he maintained that it was better to put the hand "*on* the pleura than *in* the pleura"—*Gazette Médicale de Paris*, Nov 23, 1895

Treatment of Vesico-Vaginal Fistulæ by Intra-vesical Suture ; Recovery —According to the *Medical Week*, Prof Duplay presented before the Paris Academy of Medicine, on Nov. 19, a surgical case of great interest

A woman 31 years of age was affected with a vesico-vaginal fistula, situated much too high up to permit of freshening and suture through the vagina I therefore decided to resort to supra-pubic cystotomy, followed by intra-vesical suture

The operation was performed on July 15 last After incision of the abdominal wall and bladder I easily found the fistula, which was situated transversely in the floor of the bladder, and measured about 2 centimeters in length by 1 centimeter in the antero-posterior direction With the aid of long bull dog forceps and a curved bistoury I detached the vesical mucosa all around the fistula, and freshened its edges I then placed two rows of sutures, one in the vaginal, the other in the vesical wall, the former being silk and the latter catgut sutures By this means the fistula was completely closed, both toward the vagina and the bladder. The hypogastric wound of the bladder was thereupon united by two rows of catgut sutures, one of which was placed in the mucous, and the other in the muscular coat Lastly, the abdominal wall was closed, a small drain being left in at the lower end, a slightly compressive, iodoform gauze and cotton wool dressing was applied, and a self-retaining Sims catheter was introduced The patient made an uneventful recovery No urine escaped through the vagina after the operation, and a month later she was discharged completely cured, the only disturbance being slight vesical tenesmus. I have heard from her since Recovery has been fully maintained, and her general health, which before the operation was somewhat impaired, is now excellent

Treatment of Pernicious Anemia.—Prof William Pepper is reported in the *Medical News*, Nov 23, as presenting to the class at the University of Pennsylvania his views as to the causation and therapy of pernicious anemia The case in point before the class has had for its origin some form of intestinal disease in a patient who always " bolted " his food, and who has for years had occasional attacks of dyspepsia and diarrhea The motor power of the stomach is impaired, and an atrophy of the gastric tubules has undoubtedly taken place, his debility is extreme, and there exists a high degree of oligocythemia with corresponding oligochromemia and poikilocytosis There are microcytes and macrocytes, misshapen cells and nucleated cells, giant cells and dwarf cells The treatment is perhaps less obscure than the causation To begin with, muscular exercise should be forbidden Absolute rest in bed is for some weeks imperative and almost complete confinement to bed is advisable for a considerable period longer General massage is an excellent adjuvant, and should be persistently employed Inunctions of cod-liver oil, given once daily, have seemed to Dr Pepper to improve nutrition, and they are being given to this patient

The treatment, by dietary and by remedies, of the case in question was carried out along the following lines

"The gastro-intestinal tract demands the most careful diet and treatment, and in these matters each case must be studied for itself This man's diet consists of finely minced Hamburg steak delicately broiled, so that all the juices are retained, dry toast or stale bread, and hot milk with a little coffee in it In the last few days he has seemed to enjoy eating, and he does not suffer from nausea However the diet may be modified, it must be highly nourishing, given in small quantities and often Hydrochloric acid is generally indicated, and this man is given a couple of drops after each meal His bowels have been loose, and we have been washing out his colon daily with warm water and following this with an injection of a weak solution of silver nitrate Were not his stomach so well-behaved with his present diet and treatment I should practice gastric lavage, and cases have been reported where striking results have followed this procedure.

'For the blood we have one drug that exerts over many of these cases a most marvelous influence—arsenic Under its use some cases recover entirely, others improve greatly only to relapse The drug must be pushed to the limit of tolerance—10, 15, or even 20 drops of Fowler's solution thrice daily, guarded with a little opium to counteract the tendency toward diarrhea You must watch carefully for constitutional signs of over-action, as puffiness under the eyes and gastro intestinal irritation and should these appear the dose must be reduced An irritable stomach does not in itself contraindicate arsenic, as the stomach often improves under its influence. But should the drug aggravate the irritability of the stomach, it should be administered hypodermically Iron rarely does good early in the treatment, when convalescence is well established it may be advantageously combined with the arsenic Lately bone marrow (of lambs and calves) has been tried in the form of glycerol extracts, in some cases with reported good results In extreme cases the hypodermic injection of large amounts of normal saline solution, direct transfusion of blood, and the injection of defibrinated blood have all been resorted to in some reported cases to good advantage Treatment must be persevered in for a long time after the blood has been brought back to a good condition, and the patient must be kept under the most careful dietetic and hygienic conditions, and guarded in every way against the all too frequent relapse This man has been under treatment nearly a fortnight He expresses himself as feeling better, his appetite has improved, he bears the large doses of arsenic well, and his blood has gained 7 per cent in hemoglobin and 100,000 red cells over the estimation on admission"

Conservative Surgery at La Pitie—An Old Treatment Revived.—If the views of Dr Paul Reclus are correct and borne out in the future history of hospital surgery, the days of the amputator are over A recent clinical lecture by that well-known Parisian practitioner and professor repeats and emphasizes views that he has already given to the profession He has already spoken upon the subject before the Congress of French Surgeons for 1895 The clinical lecture from which we are about to quote is given *in extenso* in the *Medical Week* for Nov 22, as delivered by the author at the La Pitie Hospital, and may be considered to be the pronunciamento of a radical conservatism in surgery Will it survive? Is the hot water "embalming" process greater than the Catling? The former is a small part only of an enthusiastic presentment of these highly vital questions Prof Reclus says

"Whatever the extent or gravity of the lesions, *I never, under any circumstances, amputate* the injured limb, but merely wrap it in antiseptic substances by a veritable embalming process, leaving nature to separate the dead from the living tissues This method of treatment possesses the double advantage of being much less fatal than surgical exeresis, and of preserving for the use of the patient, if not the entire limb at any rate a much larger part thereof than would be left after amputation

"I should not have the courage, however, to advocate this uncompromisingly conservative treatment, were it not for the excellent effects of hot water, which I use freely Briefly stated, my procedure in such cases is as follows The patient, who is almost invariably in a state of collapse from the shock, pale, anemic and cold, is placed on the operating table, where he is wrapped in hot blankets, only the crushed limb being left exposed The skin of the latter is shaved, all fatty substances are removed by the aid of ether, alcohol or potassium permanganate, and when this preliminary disinfection has been thoroughly done, the injured parts are carefully cleansed

'The principal agent employed for this purpose is hot water from a cistern placed at a sufficient height above the bed to insure a forcible jet The temperature of the water should be between 60° and 62° C, but not higher, for, if it should reach 64° C, the heat would be sufficient to alter the albuminoid constituents of the tissues This jet of hot water is made to irrigate all the injured surfaces, and to penetrate into all the hollows and under all the detached parts of the wound, without exception This is the only way of removing all clots, and to wash away all foreign bodies, together with the microörganisms they may contain

'The advantages of this application of hot water are threefold In the first place, at this high temperature it is antiseptic It not only removes such germs as may have entered the wound from contact with the clothing or ground, but it also neutralizes their effect At 62° C the development of microbes is checked Miquel has shown that when 1 cubic centimeter of liquid was maintained for fifteen minutes at a temperature of 55° C, the number of bacilli contained therein fell from 3,500 to 33 Moreover, I mix with the water a small quantity of antiseptic substances, the potency of which, as is well known, is greatly increased by heat

'In the second place, hot water is hemostatic Oozing is arrested, the smaller veins and arterioles contract, vessels of a certain size continuing to bleed, however, unless the recoil of the coats and the retraction of the intima has resulted in the formation of an obstruction

"In the third place, water of a higher temperature than 60° C helps to compensate for the loss of heat resulting from the bleeding and especially from the traumatic shock The dangerous hypothermia gradually gives way, and in the majority of cases under my observation I have found that when the patient left the operating table his temperature had already risen to normal instead of being subnormal, as is the rule after an amputation has been performed for the purpose of remedying the effects of a traumatism I need hardly insist upon the improvement in the prognosis under such conditions When this irrigation has been done, it only remains to have recourse to the process of embalming which I have described in the paper referred to above"

Society Notes

A REGULAR meeting of the Cuyahoga County Medical Society was held at Cleveland, Ohio, Dec 5——At the annual meeting of the Society of Medical Jurisprudence held in New York, Dec 9, the following officers were elected President, Edward F Brush, M D, Vice-President, S B Livingstone, Corresponding Secretary, R Safford Newton, M D ——The Northwestern Ohio Medical Association held its fifty-first semi-annual meeting in Findlay, Ohio Dec 12-13 The following officers were elected President, Dr Charles Graffe, Sandusky, Vice-President, Dr Charles Slocombe, Defiance, Secretary, Dr J Parker Baker, Findlay, Assistant Secretary and Treasurer, Dr T M Gehrett, Deshler Defiance was chosen as the next place of meeting, Dec, 1896

Hospital Notes

THE McDONALD MEMORIAL HOSPITAL OF NEW YORK CITY — This is a new hospital for colored persons and others to be located on West Twenty fifth Street, adjoining the Bethel

Church The McDonald Memorial Hospital was incorporated about three months ago It is named after the late Dr McDonald, the most eminent colored physician of New York The hospital will draw no radical line Its services will be free to all, irrespective of race or creed It is founded to bring advanced medical aid closer to the people It will open with a free dispensary When the necessary funds are available there will be a training school for colored nurses It will depend for support chiefly upon the colored churches and the contributions of the white Liberal donations have been promised toward the establishment and support of a well-equipped pharmacal department, and also of a surgical clinic with the kind of apparatus, etc , that is most essential to such an institution

The State Hospital for the Insane in Kings County, New York —Some changes have been made in the personnel of the New York hospitals for the insane At the asylum in Flatbush, a ward of the city of Brooklyn, Dr Robert M Elliott, of Rochester, has been appointed by the State Board of Lunacy Commissioners as Medical Superintendent The new appointee will hold the same relative position at Flatbush that Dr Deering does, who is in local charge of St Johnland Dr Sylvester, the General Superintendent, has been performing the dual functions at Flatbush for some years, and the creation of this new office will give him a better chance to look after both institutions The new officer has been for five years an assistant at the hospitals at Rochester, and his present change is in the line of a promotion Since the State took charge of the King's County insane, under the State Care Act, they have created this office of Medical Superintendent at Flatbush Their first appointment was Dr Thomas E Branford, of the Hudson River State Hospital, but he speedily resigned after viewing the accommodations offered him

The Masons have volunteered to furnish a room in the new city hospital at Binghamton, N Y ——The directors of the Pittsburg Chamber of Commerce have unanimously adopted a resolution recommending that the municipal authorities adopt measures to provide isolated hospitals for contagious diseases ——The financial report of the Southern Indiana Hospital for the Insane shows that the cost of conducting the institution during the past year has been nearly $85,000 The Superintendent reports $15,000 expended out of the special appropriation for the construction of new buildings, with a balance of $15,000 ——The third annual report of the Massillon, Ohio, State Hospital has been made The total disbursements during the year were $64,446 17, and the report showed a balance of $194 56, Nov 15, 1895 The trustees ask that $300,000 be placed at their disposal for the purpose of improvements and additional buildings

Detroit Notes

At the regular meeting of the Detroit Medical and Library Association Thursday, Dec 8, Frederick Robbins read a paper on "The Use and Abuse of Urethral Injections" The author reported two recent cases of gonorrheal urethritis cured in less than ten days by wiping out the first ten inches of urethra with Ag No$_3$ gr x–xx to the ounce, followed daily for five days with large douches of Hg c½ I–40000 He condemns the routine use of the syringe as unscientific, useless and dangerous, as it is only useful in the latter stages of an uncomplicated anterior urethritis He emphasized the fact that the Ultzmann syringe is absolutely essential for treatment of many cases of posterior urethritis

The Wayne County Medical Society held a regular meeting Dec 12 The subject, "Hypnotism," was presented by Cassius M MacDonald in an interesting manner

The Report of the Health Office for week ending Dec 14, 1895 Deaths under 5 years, 27 , total, 75 Births Male 36, female 37 , total, 73 Contagious diseases for week ending Dec 14, 1895—Diphtheria Last report 30, new cases 6, recovered 14, died 15, now sick 40 Scarlet Fever Last report 21, new cases 6, recovered 2, died none, now sick 25 Smallpox Last report 1, new cases 2, recovered none, died none, now sick 3 Measles Last report none, new case 1, recovered none, died 1, now sick none

Cincinnati Notes

Mortality Report for the Week Gives the Following —Membranous croup 1, cholera infantum 1, diphtheria 3, typhoid fever 6, zymotic diseases 4, cancer 3, phthisis pulmonalis 14, other constitutional diseases 4, apoplexy 7, bronchitis 4, convulsions 5, gastritis 2, meningitis 3, nephritis 2, peritonitis 3, pneumonia 8 other local diseases 21, violence 7, under 5 years 27 Total 110 Rate per 1,000, 17 02 Corresponding week 1894, 137 , 1893, 193 , 1892, 113

At the Academy of Medicine Dec 9 Dr E W Mitchell read an elaborate paper on "The Anemias," which was discussed by Drs F Southgate and N Wolfstein

Dr J C Culbertson has been elected Commander of the E F Noyes Post G A R , of this city

The Announcement of the new Laura Memorial College appears with the following faculty J M Withrow, Professor of Gynecology , J L Cleveland, Theory and Practice of Medicine , E W Walker, Surgery , G F Sudhoff, Histology , L S Colter Obstetrics , E M Riley, Materia Medica , O M Sprague, Chemistry , S E Allen, Pathology and Bacteriology , G W Ryan, Orthopedic Surgery , Giles S Mitchell, Diseases of Children , A G Drew, Dermatology , C R Holmes, Ophthalmology , J E Boylan, Laryngology , Chas E Everett, Medical Jurisprudence

An Ambulance service has been established in connection with the City Hospital The Hospital Corps of the First Regiment of Infantry O N G , located at Cincinnati under Drs F W Hendley, G I Cullen and Chas H Castle, has been granted the privilege of the patrol wagons for this service, and the members have volunteered their services in this line of work Two members of the Corps are privileged to admission at the Cincinnati Hospital each night

An epidemic of typhoid fever is raging at Waddy, Ky The scarcity and impurity of the water supply is thought to be the cause

The report of the Columbus State Hospital shows a per capita cost of $138 69 in comparison with $144 91 of 1894 At the beginning of the year there were 652 male and 612 female patients on the rolls There were admitted during the year 185 males and 152 females , death rate 5 25 per cent

Dr W D Hoge, Dr J L Hervey and several others were arrested at St Clairsville, Ohio, charged with running the smallpox quarantine They all live at Martin's Ferry, which is quarantined against and the accused, it is alleged, passed the lines by denying their place of residence

Bellaire, Ohio, is now cut off by quarantine from West Wheeling, Bridgeport, Ætnaville and Martin's Ferry Street cars have been stopped There are about 25 cases of smallpox and a large number of suspects on hand

Philadelphia Notes

Extirpation of the Gasserian Ganglion —Dr W W Keen, at the last meeting of the Philadelphia County Medical Society, presented two patients, upon each of whom he had performed Krause's operation for removal of the Gasserian ganglion for inveterate facial neuralgia , both were men, and represented the earliest and the latest of a series of six cases The first one had been operated upon twenty-six months ago, the last one only nineteen days before, and each reported complete relief from the former attacks of pain The chief points in the communication were 1, the control of hemorrhage (by packing with gauze, deligation, etc) with comparative ease, in a case of rupture of the middle meningeal artery at the foramen spinosum He did not favor preliminary ligation of the internal carotid artery on account of the possible ill effect upon the nutrition of the cerebrum and a tendency to softening which might result, he especially dwelt upon the fact that the entire ganglion may be removed, a feat considered impossible even by so competent a critic as Horsley, until Krause showed that it could be done Dr Keen presented a specimen of the ganglion removed from the last case without mutilation, and showing the motor root The latter is not to be found in the illustrations of specimens removed by Krause, accompanying his article in the recent issue of the *Archiv für Klinische Chirurgie*, 3, the influence of the removal of the gland upon the nutrition of the chorea was shown by the tendency to ulceration after the operation This could only be overcome by stitching the eyelids together, which expedient was successful in the last case The mortality was small, only one death occurred in the six cases, and this was attributed to infection of the third case through an unaccustomed assistant The superiority of extirpation over mere destruction of the ganglion was referred to

Proposal to Establish a Pay Hospital for Contagious Diseases —A committee has been appointed by the Philadelphia County Medical Society to formulate plans and to take such steps as will secure for this city sufficient accommodation for those patients suffering with diphtheria and scarlatina, and particularly for those who desire and will pay for special hospital quarters The present Municipal Hospital has not sufficient accommodation for the present demands upon it, and no special rooms for paying patients In all probability the Council will respond to the urgent demand and will authorize the construction of additional pavilions in connection with the present structure, instead of building a new hospital

The Judson Daland Medical Society has been organized among the medical students of the University of Pennsylvania in conformity with the custom which has been introduced of late years into this time honored institution of dividing up the medical classes into groups, in honor of individual members of the faculty

The Medico-Chirurgical College has commenced work on its new clinical apmhitheater located between the main hospital building and the maternity Beside the amphitheater, the structure will contain three private operating rooms—surgical, gynecologic and ophthalmologic—with a large and complete sterilizing apparatus Provision will be made to flush the amphitheater after each day's demonstration or lecture, so as to insure surgical cleanliness During the coming year, a new six-story laboratory building is to be erected at the corner of 17th and Cherry Streets, on ground recently purchased, and the institution is to establish its own electric light plant

Dr A F A King, of Washington, Professor of Obstetrics in the Columbian University, was the guest of the Philadelphia Medical Club, which gave him a reception at the Bellevue Hotel, Dec 11 A large number of local representative physicians were present The President of the Club, Dr H A Hare, introduced Dr King, who made a most appropriate and entertaining brief address, in which he indulged in some reminiscences of his student life in Philadelphia when the University was at 9th and Chestnut Streets, and Agnew and DaCosta lecturers in the Philadelphia School of Anatomy and the old Chestnut Street Quiz Association

Diphtheria —The number of cases of contagious diseases in the city reported since Oct 1 are 957 of diphtheria, with 814 deaths In spite of isolation and disinfection, the number of cases of diphtheria do not appear to be on the decline Two cases of smallpox and one of typhus fever have also been reported

By invitation of the Surgical Section of the College of Physicians and Surgeons, Dr L McLane Tiffany Professor of Surgery in the University of Maryland, read a paper on Dec 13, on 'The Treatment of Compound Fractures of the Lower Extremity," and Dr L S Pilcher, surgeon to the M E Hospital, Brooklyn, and editor of the *Annals of Surgery*, gave the results of his personal experience in the "Ambulant Treatment of Fractures" Dr Edward S Martin of Philadelphia, made some remarks on "Fractures of the Leg Treated by the Ambulant Method," and Dr Thos F Branson reported a "Case of Fracture of the Coronoid Process of the Ulna" The discussion was general, and was opened by Dr John Ashhurst A reception was tendered the guests of the evening at the residence of Dr John B Roberts, after the meeting adjourned

Washington Notes

Weekly Report of the Health Department —The report of the Health Officer for the week ended Dec 7 is as follows Number of deaths (still-births not included), white 46, colored 40, total 86 Death rate per 1 000 per annum, white 12 8, colored 23 7 total 16 2 Death rate per annum corresponding week last year, 16 8 The death list last week was materially below the normal A decline of nigh 20 per cent in the number of deaths took place, as compared with the week before From 107 the number fell to 86 The mortality from consumption went from 17 to 7, and from acute lung maladies from 26 to 11 Two deaths from typhoid fever occurred as against 4 by the last report The prevalence of diseases of the brain and nervous organs stood at about the same degree as has been maintained for the last several weeks, while that from kidney disorders shows a fall of from 5 to 2 deaths The dangerous contagious diseases present no tendency to assume epidemic form Of the fatal cases of diphtheria reported, 2 were attended with serious complications The annual death rate for the week was 16 2, while for the corresponding period of last year it was 16 8

Alumni Association Election —At the annual meeting of the Alumni Association of the Columbian University held on the 13th inst, Dr Chas W Richardson was elected President for the ensuing year

Inspection of Beef Postponed —Secretary of Agriculture Morton has extended the time for the enforcement of the meat inspection law from Jan 1, 1896, to March 1, 1896 Shippers who fear inspection of their meats should be looked upon with suspicion Good meat can never be depreciated in value because of a proper certificate that it is from a healthy animal

For the Home for Incurables —The promoters of the endowment fund of the Washington Home for Incurables have adopted a novel scheme for raising money Cards were sent out which will just receive a fifty cent piece and hold it securely These were sent to a great many residents, and although the fund is considerable already, it is the intention to make it so large that the institution may never be at a loss for money

Surgeon-General Sternberg's Address —Surgeon-General Geo M Sternberg, U S A, the retiring President of the Biological Society of Washington, at the annual meeting last week delivered a most instructive address on the subject "The Practical Results of Bacteriologic Researches" His remarks were illustrated by lantern slides, showing the many phases of bacterial life

Pathologic Laboratory for the Children's Hospital —The pupils of Norwood Institute have raised the sum of $1,000 for the benefit of the Children's Hospital The good work was done at the suggestion of Dr S S Adams, one of the attending physicians of the hospital, who has decided the fund shall be devoted to the organization of a pathologic and bacteriologic laboratory for the institution

Physicians to the Poor —Dr Charles N Emmons has been appointed a physician to the poor Dr D G Lewis has been appointed in place of Dr H S Goodall, whose appointment expires on the 15th instant Dr F O Roman has been appointed in place of Dr C V Petteys, and Drs J R Shands and G L B Jarvis have been appointed to serve the poor during the absence of Drs T Clark and J R Devereux Dr G W Wood has been appointed in place of Dr C W Bordsall, whose appointment has expired

Benefit for the Children's Hospital —The benefit for the Children s Hospital which will take place at the National Theater Tuesday afternoon next, is attracting a great deal of attention The New National Theater School of Acting is the medium through which the benefit is given, and two plays are to be presented, the first being "My Wife's Dentist,' and the second, "Broken Hearts

To Regulate Veterinary Medicine in the District —The Commissioners will shortly present to Congress for passage a bill regulating the practice of veterinary medicine and surgery in the District of Columbia Dr Robinson, representing the District Veterinary Medical Association, appeared before the Commissioners and presented a draft of a bill which had been agreed upon by that body, and which he urged be presented to Congress for enactment

The bill provides for the appointment of a board of five examiners, who shall be members of the Veterinary Medical Association, the terms of office to be limited to three years Meetings for the examination of applicants are to be held on the first Tuesday in January, April, July and October of each year It further provides that all persons practicing veterinary medicine in the District shall apply to the board for a license, which the board may refuse, and may revoke a license for chronic and persistent inebriety, for advertising in such manner as to deceive or defraud the public or for failure to report any case of contagious disease required by law to be reported The bill also provides that all persons receiving a license to practice veterinary medicine shall register at the health office For practicing without a license the offender may be punished by a fine not exceeding $100 nor less than $50

Medical-Director Gihon's Report of the Naval Hospital —From the report of Dr Gihon the following quotation is taken The total number of cases treated at this hospital since its establishment, Oct 1, 1896, is stated at 8,065, of which number 2,525 were discharged to duty, 314 were condemned by medical survey and 118 died Over 82 per centum of the cases admitted into the hospital since its foundation have been returned to duty, 10 per centun have been invalided from the service by boards of medical survey for disabilities unfitting them for further duty, and less than 4 per centum have terminated fatally Four of the typhoid cases originated at the old barracks at the marine headquarters and two at the navy yard, one on board the Dolphin and the other on board the Dale

Medical Society of the District —At the meeting of the society held on the 11th instant, Dr Burnett reported a case of intra cranial tumor and presented the specimen Dr Beth reported a case of skin grafting for ectropion and presented the patient for examination Dr S S Adams reported a case of ulcerative endocarditis with specimens, with Dr Reed's report on the bacteriologic experiments from the case Dr H L E Johnson reported seven cases of abdominal sections (gynecological) and presented the specimens

Surgeon General Tryon's Report—In the last annual report of the Surgeon General to the Secretary of the Navy, he touches upon a most important questions The sanitation of Government war vessels He says " Up to a very recent date no ship had ever been constructed in which the question of the health of the crew had been scientifically considered in the design itself, and there have been few after construction in which intelligent effort has been directed to the preservation of health The great idea in all time has been to sweep the sea—to have dominion over the waters For this purpose ships have been built as mere engines of war, and with but little consideration for the fact that the most indispensable mechanical instruments are men themselves Ships were few, and represented much time and money, men were many, and could be easily replaced And thus for hundreds of years much more anxiety was exhibited in preserving arms from rusting and cordage from rotting than in considerations affecting the health of crews

Report of the Superintendent of Charities —From the valuable report of the Commissioner of Charities the following quotations are made "As shown by the report of the sanitary officer to the superintendent of the metropolitan police, public patients were sent to the hospitals by that branch of the District service during the late fiscal year as follows Freedman's Hospital, 936, Providence Hospital, 848, Hospital of the Washington Asylum, 292, Garfield Hospital, 255, Emergency Hospital, 121, Homeopathic Hospital, 97, Columbia Hospital, 66, Children's Hospital, 31, and 5 to the Sibley Hospital Many patients in maternity cases are sent to Columbia and other hospitals from dispensaries The Children's Hospital receives through the same channel, as well as from child caring asylums Accident cases are brought to the Emergency Hospital by its own ambulance service, and other medical establishments accept inmates coming by transportation, public or private, other than that of the sanitary office The figures given above show a total of 2,751 cases sent to hospitals by the sanitary officer during the fiscal year ended June 30, 1895 During the succeeding quarter, the months of July, August and September, 1895, there were sent to the hospitals in the same manner 1,102 patients, or at the rate of 4,408 cases a year The number exceeds that recorded during any previous quarter, and the fact shows that, even when no serious epidemic prevails, the hospital accommodations of Washington are no more than adequate to the demands upon them During the summer and fall at all places of medical refuge, the usual accommodations were fully occupied, and it was necessary to improvise additional ones in order to meet the urgent demands for treatment of public patients There were also a sufficient number of case of the minor infectious cases treated by make shift isolation in the homes and improvised isolated quarters furnished by the medical charities to further enforce the necessity of final and sufficient action upon this long-postponed but vital subject

Emergency Hospital Examinations —An examination will be held on the 20th inst at the Central Dispensary and Emergency Hospital to fill three vacancies in the house staff

---

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army from December 7 1895 to December 13 1895

Capt William P Kendall, Asst Surgeon, upon the expiration of his present leave of absence is ordered to Ft Sam Houston Texas, for duty

First Lieut John S Kulp, Asst Surgeon will upon the expiration of his present leave of absence, be relieved from duty at Ft Spokane Washington and ordered to Ft Walla Walla, Washington, for duty

Capt William B Banister, Asst Surgeon, leave of absence granted is extended one month

First Lieut James M Kennedy, Asst Surgeon, leave of absence granted is extended two months

Capt Charles E Woodruff, Asst Surgeon now on leave of absence, is ordered to proceed from Washington D C, to Ft Snelling Minn and report for temporary duty without delay

RETIREMENTS

Major Richard S Vickery Surgeon, is retired from active service this date Dec 7 1895

Capt Freeman V Walker Asst Surgeon is by direction of the President wholly retired from active service this date, Dec 4 1895

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending December 14, 1895

P A Surgeon G T Smith, detached from the "Ranger" and ordered to the "Adams"

Asst Surgeon M K Johnson ordered to the Naval Laboratory and Department of Instruction New York

---

Change of Address

Brown, F H from Pythian Temple to Widdecomb Bldg, Grand Rapids Mich

Eads S O from Beaver Crossing, Neb to Science Hill, Ky

PRIMARY OR ACUTE CONFUSIONAL INSANITY

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY DR JAMES G KIERNAN

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE PROFESSOR OF FORENSIC PSYCHIATRY, KENT LAW SCHOOL PROFESSOR OF NERVOUS AND MENTAL DISEASES MILWAUKEE COLLEGE FOREIGN ASSOCIATE MEMBER FRENCH MEDICO-PSYCHOLOGICAL ASSOCIATION

Fifteen years ago, Dr E C Spitzka[1] described under the term "primary confusional insanity," (an approximation of the German title "Verwirrheit" applied to the same mental states) a form of insanity "which develops rapidly on a basis of cerebral exhaustion Consciousness is blurred in parallelism with the conceptional disturbance and the patients on recovering have, as a rule, but very crude recollections of their condition Its duration is variable, comprising weeks and months The prognosis is, as a rule, as good as that of stuporous insanity, which condition it also resembles as to etiology, emotional shock, cerebral overstrain, exhausting diseases and excesses being the principal factors responsible for primary confusional insanity The patients suffering from this psychosis, after a rapid rise of their symptoms during a period of incubation rarely exceeding a few days, present hallucinations and delusions of a varied and contradictory character The delusions may resemble those of mania, and more often those of melancholia, but no emotional state is associated with them The patients assert in the same breath that their property has been stolen and that they are going to take part in some State affair There is a surface resemblance between the confusion of mania and that of acute confusional insanity The confusion of mania is not the expression of a genuine confusional state, but of a disparity beween the ideational items and of the word channels through which they seek exit That of acute confusional insanity is an expression of a true essential confusion of ideation "

Several years ago I employed[2] this designation in connection with an analysis of cases occurring in the literature In 1889, in an article clearly suggested by Dr Spitzka's work[3] on insanity, Dr H C Wood[4] used the same term to designate this class of cases Antecedent to Dr Wood, Dr H N Moyer[4] had testified to the existence of certain forms of insanity bearing this designation The term was adopted from Dr Wood by Dr W Osler[4] at this time, who employed it to designate the same class of cases Dr Conolly Norman[5] also employed the term to designate this class of cases, taking it from Spitzka

Three years ago I reiterated an analogy made in 1888 between the psychoses produced by various causes of cerebral exhaustion while classifying them under this title This psychosis has been carefully discussed by Dr J Ferguson, of Toronto, who is somewhat biased by a seeming analogy between typhomania and acute or primary confusional insanity Confusion of the two psychoses is not infrequent, nor is it deserving of reproach, albeit typhomania is a furibund, not an exhaustional psychosis

The features presented by acute or primary confusional insanity may be gleaned from the following case of varied etiology cited from those which have come under my observation

Case 1—A young man brought up on a farm was much given to the perusal of sensational literature He was very superstitious and frequently expressed a fear of ghosts The boys of the neighborhood becoming acquainted with his weakness devised a plan to frighten him with a pretended spectre at midnight He always slept with a large revolver in easy reach During the day the ball cartridges were replaced by blank cartridges and the weapon restored to its usual place At midnight the victim of the practical joke was awakened by a seeming spectre which stealthily entered the room and stood with outstretched arms muttering unintelligibly The victim hurriedly grasped the revolver and sat upright in bed, dumb with fear The ghost advanced a step, the muttering continued When the young man, wrought up to almost a frenzy, drew the weapon and stammered, "If you are a man, I shall kill you, if you are a ghost, this won't hurt you" and fired There was a quick motion of the shrouded arm and the bullet was thrown back striking the headboard A second time he took deliberate aim at the figure and fired Again a motion as if catching the bullet and it was thrown back upon the bed He fired a third, a fourth, and a fifth shot, only to have the bullets hurled back with noiseless motion from the ghostly figure Then for a brief moment he sat as if transfixed, gazing with mute bewilderment, when with a wild shriek of terror he fired the last blank cartridge and hurled the pistol at the ghost When the pretended ghost revealed himself, the victim was found in a dead faint which gave way to an incoherent frenzy, accompanied with marked initial hallucinations of sight and hearing He recovered after three months' treatment in an asylum One of the planners of the joke became insane through remorse and exhibited the like symptoms, but also finally recovered

Case 2—A man 50 years old was admitted in a state of violence much resembling that of alcohol The patient who had a brother insane, had been perfectly well up to a week prior to admission when he was attacked by rheumatism involving the knees, ankles and wrists accompanied by a high fever The third day after the appearance of the fever the patient was exceedingly delirious Home treatment was for a time pursued, but his violent attempts rendered transfer to an asylum necessary On admission the patient had a temperature of 101° His knees, ankles and wrists were swollen Psychically he was incoherently agitated and presented hallucinations of taste, hearing and sight The day after admission his temperature rose to 105°, his agitation increased, he being with difficulty kept in bed, desiring to get up continually and drive off a legion of devils pursuing him He refused to take eggnog on the ground that it tasted and looked like blood Within three days the patient became comparatively rational and by the end of the second week the mental symptoms had entirely disappeared The patient soon began to improve physically and was finally discharged He recovered four weeks after

Case 3—The patient had been in very good health up to about three months before the admission which occurred during the year 1874, when he was attacked by headaches for which, on the supposition of its being malarial, three grains of quinin were prescribed three times a day After taking three doses of this the patient was seized by a violent attack of incoherent frenzy, with marked hallucinations of hearing of a depressing type There was considerable dimness of vision, these phenomena persisted for three months as the quinin was continued and the patient treated with morphine subcutaneously On admission to the insane hospital, which was at length rendered necessary, the patient was in the condition already described and was placed under choral and hyoscyamus as a hypnotic and conium to quiet motor excitement Under this treatment the patient was in fit condition to be discharged within six weeks[6] after admission He manifested, a day previous to discharge, some slight evidences of malaria, whereupon quinin was administered which had the effect of bringing on a fresh attack of frenzy with the same symptoms as previously The quinin was stopped and the same treatment was instituted with equally good results

Case 4—A painter 40 years old became incoherently insane during his third attack of lead colic He felt bees stinging him and saw them fly through the air at him After three weeks home treatment he recovered

Case 5—A girl 6 years old was attacked by scarlet fever, which went through the early stages in the usual way About the sixth day after the scarlet eruption appeared the temperature (104°) sank to 98° and the child became extremely restless and violent She had been frightened by a Chinaman two weeks before the attack of scarlatina She now complained that she saw him at the window with his hands outstretched to grasp her This condition continued for two days when it gave way to an incoherent hallucinatory state, accompanied with great agitation The patient recovered in a week[7]

Case 6—A woman 40 years old, who had been engaged in harassing litigation, was grossly insulted by a lawyer during an interview She wandered away in a stupid state, but was picked up by a friend who took her home She remained in this stupid state for thirty-six hours and then became incoherently hallucinated, visually and auditorially Three weeks later she had fully recovered but retained a very confused recollection of her illness

The phenomena presented by this psychosis bear a superficial resemblance to the episodiac excitement of paranoia as well as to the period of transformation Both are attended by hallucinations and agitation, but in paranoia there is an underlying intellectual element which, together with the precedent history, serves for demarcation The febrile disorders often set up a neurosis which serves secondarily to the acute confusional insanity as a basis for the develop of paranoia Such an association is, however, purely fortuitous Acute disorders may expedite in degenerate subjects the development of paranoia after an acute confusional insanity, but this has no special relation to the succeeding psychosis since paranoia was simply hastened in its development, not created by the confusional insanity This fact, however, led Westphal erroneously to classify acute confusional insanity with paranoia Rosenbach has recently pointed out these resemblances in a very graphic manner The temperature in typhomania and the furibund symptoms differentiate it from acute confusional insanity as well as the greater mental defect Treatment consists in proper nutrition, quiet and relief of agitation The prognosis is usually good

A question has been raised as to the essential etiologic factor Kraepelin,[8] who studied psychoses of this type most extensively, is of the opinion that to systemic nervous exhaustion, not to toxic elements, it is due This is also the opinion of Moeli,[9] who in a case resultant from lead colic, claims that the exhaustion from the colic, not the lead poisoning, was the chief cause of the psychic symptoms Binswanger[10] in discussing the psychosis as it supervenes on fever from brass poisoning in brass founders, inclines to Moeli's opinion

As will be seen by the quotation from Spitzka, he regards the adynamia as the essential basic etiologic factor This opinion of Spitzka has been adopted by Dr H C Wood Ferguson insists that toxic factors play a part in certain cases This may be granted but they, as a rule, produce no symptoms differing from the cases developing on exhaustion from other causes This adynamia is, as many of the older clinicians have shown, simply a nervous asthenia produced by various causes ranging from psychic to toxic On it the whole group of adynamic psychoses designated as primary or acute confusional insanity develops During fourteen years private and insane hospital practice in Chicago, I have observed 103 cases

SOME QUESTIONS OF RESPONSIBILITY IN OPIUM AND COCAIN INEBRIETY

Read in the Section on Neurology and Medical Jurisprudence at the Forty sixth Annual Meeting of the American Medical Association at Baltimore Md May 7-10 1895

BY T D CROTHERS, M D
SUPERINTENDENT WALNUT LODGE HOSPITAL, HARTFORD, CONN

Within a recent period the question of responsibility and accountability for conduct and acts of persons who are known as opium, cocain and other inebriates has been raised in courts, and referred to medical men to answer The confusing character of the medical evidence offered suggests the need of a more careful study of some of the general facts common to these cases So far, the contested cases have been disputed wills strange criminal assaults, thefts and defalcations, and other crimes usually devoid of premeditation and ordinary judgment in the execution. The larger number of these cases have none of the symptoms of insanity as understood in courts and text-books The prominent manias and delusions and eccentricities of talk and conduct are wanting. The opium cases in public are quiet, secretive, abstract and harmless The cocain takers are talkative and excited, but equally shrinking and retiring The other drug takers also avoid publicity, and when exposed seem dull, stupid and indifferent Many of these persons retain their position in active life, and appear normal, attracting no special attention by acts or words

The commonly accepted opinion, which is supported by many medical men, is that the use of narcotics daily is not incompatable with ordinary intelligence and average judgment, that it is possible to use such drugs for a long time and be mentally capable Such views are not sustained by scientific examination of cases

Practically, all uses of narcotics are the abnormal demands of brain centers for relief Same condition of fatigue, degeneration, and departure from a normal state, is manifested by irritation, pain and suffering this the narcotism of these drugs quiets Later states of poisoning follow, from the derangement of cell nutrition and elimination of waste products, and the increasing chemical disturbance of the higher processes of tissue and cell growth All narcotics by their paralyzing action on the sensitive

nerve centers, both poison, starve and exhaust them, and thus destroy the power of the higher centers to recognize the actual condition and relation of the surroundings

This is practically insanity in its broadest sense The brain is impaired, its delicate functional processes are lowered, its capacity of reasoning and of comparison is broken up, all sensation is deranged, and co-ordination becomes more and more difficult Both theoretically and literally, the highest functional activities of the brain suffer most The lower organic functions of digestion, nutrition and elimination show little sign of derangement in the early stages The effect of a single dose of narcotic drugs is noted in the diminished sensitiveness to all impressions from both external and internal sources The knowledge which sensation brings to the nerve centers is defective and misleading Events and their relation are obscured and the capacity to discriminate is weakened or destroyed

It is the masking and concealing of these derangements that makes them difficult to be understood These drug-inebriates quickly become automatons, following an accustomed line of act and thought, and in this way seldom manifest their real condition Later egatism and delusions become so prominent that the damaged brain is apparent In a practical study of cases where this question of sanity and responsibility is brought into prominence, the facts of heredity, and the mental and physical condition of the person before drugs were used and the effect of those drugs on the mind are the essential facts to start from

The following cases illustrate the influence of heredity in this problem A left a will which was contested He was a business man of excellent judgment and much respected For the past ten years he had used opium No history could be obtained of the reasons for using opium He had been quiet, secretive and reserved all his life, never showing any special interest in his family or friends, and avoiding company unless on business The death of his wife seemed to deepen his secretiveness, for he would see no one but his confidential clerk, and through him execute orders and business transactions The last years of his life he manifested alarm and intense anxiety at the nature and quality of the food served him He would go to the kitchen and question the cook as to the method of preparing the food There have been certain parts of the food especially sent to his table He gave his property to a distant nephew and only a small part to his children The heredity indicated a father who died in an insane asylum, a mother very eccentric who died in childbirth Both grandparents were inebriates and mildly insane Two uncles were epileptics, one aunt an imbecile, and several cousins feeble minded and paranoiacs From this heredity and history, with the unusual act of the will, his irresponsibility was decided

B was before the courts charged with bigamy He came from a degenerate family, marked by hysteria and eccentrity on the female side, and inebriety, epilepsy and imbecility on the male side Both parents were paranoiacs of alternate exaggerated and depressed emotions, in constant conflict with the surroundings and the persons they came in contact with He had been an alcoholic and changed to opium He was a commercial traveler for a brewery, and was feeble minded in many respects The act and his heredity and present condition pointed to irresponsibility, want of control and impaired consciousness of right and wrong

In a study of the physical and mental condition of persons before opium was used, the following are selected as typical cases C, a lawyer who was excessively egotistical and bold at times, then manifested unusual timidity and feebleness of character before the use of opium, became involved in a swindling scheme He had been considered an unreliable enthusiast who joined all new schemes and theories that came up and deserted them as quickly He was credulous, skeptical and suspicious, alternately At one time he was intensely selfish and grasping, at another, he would be very generous and benevolent This instability extended to all his mental and moral activities and became notorious After some fever he began to use opium and became secretive and cautious Delusions of neglect and persecution were followed by dishonest acts and arrest, with conviction and sentence to prison

D was an erratic, passionate merchant who was in constant difficulty with his customers, always having litigation to secure and preserve his rights In his family he was harsh, overbearing and suspicious He manifested constant fear and alarm of being cheated For some unknown reason he became an opium inebriate, and two years later was convicted of incendiarism, burning a neighbor's property to keep it from being occupied by a supposed enemy

In both of these cases the evidence clearly indicated a degree of insanity and degeneration before opium was used The responsibility of both cases was an open question before opium was used, but after, it appeared to be a settled fact How and to what degree the use of opium has broken up normal reason is the next essential inquiry The cases vary so widely it is difficult to point out any particular class of symptoms common to all The following case has attracted much attention

E, an opium taker, proved to be a defaulter of a large amount He had been an ambitious, energetic banker, who for many years overworked and neglected ordinary rules of health He became wealthy, was temperate, honest, lived abstemiously and was considered a man of good judgment and highly respected After a severe attack of the prevailing influenza, he began to use opium A year later he showed marked change in his habits and manner He was dull and stupid and seemed to have confused notions of many things where he was formerly clear and prompt His temper became more irritable, and he was suspicious Unusual fears were manifest to prevent his associates from robbing and taking advantage of the company New books were opened and expert examinations made of accounts, and explanations demanded of all possible matters This sharp espionage was continued for three years, becoming more offensive every year, when a board of directors made an examination of his own accounts finding a large defalcation An attack of acute mania followed the exposure, and later imbecility and death

F was arrested for wrecking a train by placing obstructions on the track He had been for years a reputable mechanic, and from the death of his wife and loss of his property, with illness, became an opium eater He worked for the railroad, and was discharged, then gradually developed delusions of persecution He grew secretive and suspicious and talked to himself when alone He wandered round the country in the daytime, coming in late at night, only working to get sufficient money to purchase opium On the trial he could give no idea of his acts and conduct from the day before the act to two days later, and seemed not to realize the crime of which he was accused

Delusions of injury by others are not uncommon Thus a woman who used opium accused her physician of criminal assault A business man asserted that he had signed a contract by threat and force of a partner, a husband asserted his wife had secreted stocks and bonds, and affirmed they were lost When confined in an asylum, these delusions assumed the form of persecutions and efforts to keep them away and take their property from them

In a medico-legal case, if the fact of using opium is established, it is necessary to make a thorough study of the history of the person The facts of heredity will indicate a constitutional tendency and bias to certain general forms of degeneration The facts of his history, before using opium, points to favoring causes and conditions that would most likely find relief in opium and narcotism The exciting and predisposing causes which led to the first use of opium, and the effects on the conduct and character of the person, with the length of the addiction, are often the central facts of the case Lastly, the act or crime committed, its possible motive, and the circumstances associated with it From these facts the possibility and capacity to think and act sanely may be determined

In all these cases two conditions are present One, alteration of character and conduct, the other of enfeeblement and deficiency The latter may be congenital and the normal state of the person He may be through defect, disease, and other causes, mentally enfeebled and unstable, deficient in judgment and average reason Opium will intensify and increase this condition, which may be far removed from imbecility and dementia, and yet it is clearly degeneration, and the power of recognition and discrimination of the relations of duty, obligation, and adjustment be wanting This condition of lowered intelligence and morality, with reason and judgment below the plane of normal consciousness, is clearly irresponsibility In the former case, where simply alteration of conduct and character are the most prominent symptoms, opium deepens and widens these changes

These are some of the cases which pass unobserved through life, attracting no attention except among those intimate with them When they commit crime, make strange contracts, ignore all claims of duty and obligation, make unreasonable wills, the various questions of mental soundness are raised The use of opium, no matter for what purpose, is clear evidence of degeneration, not when taken at long or irregular intervals, but when used continuously The activities of the brain are reduced and all the higher processes which control and regulate the affairs of life with judgment, prudence and restraint are lowered to an automatic level As a result, such acts manifest this condition more than ideas The gratification of the senses, regardless of consequences, grows more and more dominant Indulgences in so-called pleasures are the leading motives, and considerations of family, laws, society, duty and obligation grow constantly feebler He retrogrades back to lower levels, and yet in this dissolving process he may not have any of the more common signs of insanity and imbecility Courts and legal methods of judgment may be unable to find evidence of irresponsibility, and yet it exists, not based on any class of symptoms, but on a general history and comparison of conduct and character

This region of alteration of character, and the growth of the ego, with increasing feebleness of the higher function, cerebral activities, must be recognized and studied While the case may remain in this state for a long period, it is liable any time to pass into dementia or general paralysis, and the longer opium is used the more pronounced the organic changes become Every case must be judged by itself The question of responsibility is one of degree The use of opium has put the man in an abnormal condition in which his mental faculties are crippled To what extent, and how far he has become disabled and made incompetent to think and act wisely, are the questions The general principles which govern these cases apply to all other narcotic addictions

The physiologic action of cocain resembles alcohol in first exaggerating the mental functions, then depressing them Opium reduces the functional activity of the brain centers and cocain exalts them In one case a form of melancholy follows, in the other, delirium and mania comes on In both, the lowering of the higher brain centers is followed by the rise of the lower egoistic impulses The exaltation from cocain becomes delirium after a time, with cell irritation, fatigue, confusion and exhaustion The depression from this temporary elevation and exaggeration of cell activity demands relief in the repetition of the drug, and after a time organic changes begin, with degeneration and impairment The cocain taker more often commits crime against persons than property Such crime will be fitful, impulsive and lack premeditation and motive The cases that have been contested have been assaults, thefts, and attempted injury of persons without cause Several wills have been disputed where suicide followed the execution of the paper Some cases have been kleptomaniacs, and most of the cocain takers have turned to alcohol and opium for relief Hallucination and delusions are very common, but usually transient and recognizable by the person when the immediate effects of the drug pass off The cocain inebriate will at times manifest a degree of mental clearness and superior judgment that is unusual, but this is simply masked delirium and soon ends in confusion and delusion Ideas and conduct are delusional and transitory, and will not bear the test of examination and comparison General paralysis begins with a period of cocain inebriety, and the treatment and removal of the cocain brings to light this disease Cocain may be taken for some time without recognition in the changed character and habits of the case, but a careful inquiry will show a steady decline and debility of all the higher mental operations

A, a physician who had used cocain secretly for two years, assaulted a stranger in his office It appeared that he was laboring under the delusion that detectives were hunting for evidence against his character B ran away with a large amount of money belonging to the firm he was connected with He was a secret cocain inebriate, and had delusions C, a woman, used cocain and was a notorious kleptomaniac, manifesting cunning and judgment in concealing her real condition

As in opium cases, each one presents different phases and has to be judged by the facts peculiar to it Crimes of such cases often come from concealed hallucinations, particularly of theatening voices The act in its sudden impulsiveness indicates some condition of aural or visual disturbance One very prominent symptom of mental derangement is loquaciousness, and uncertainty and indecisiveness of thought Correspondence never comes to an end, one letter suggests another, and so on indefinitely The same feature is noted in conversation, continuous, random, vague thoughts and opinions, all tinctured with delusions of vigor and strength, and boasting of what they have or can do

The fact that cocain is used medico-legally is presumption of general brain debility and various degrees of irresponsibility In a disputed case, the same thorough history should be obtained of the heredity, previous health and present condition as in opium cases This, in connection with the fact that cocain used continuously rapidly develops mental confusion and intellectual disorders, making it impossible to understand the nature and character of the acts and conduct, would go far toward proving irresponsibility in a given case

A number of drugs have recently come into medico legal medicine in similar questions It may be stated as a general fact that all narcotics or drugs which may possibly cause intoxication are poisons The brain both functionally and in its organic structure is injured, its integrity is impaired Hence any form of drug addiction is open to the suspicion and most reasonable certainty of lowered consciousness of right and wrong, and general incapacity of reason These drugs are taken for their effects, which give relief in most cases Alcohol and opium are the most prominent Cocain, chloral, chloroform, ether, camphor, belladonna and others less prominent are used in the same way The effects are intoxications or states of poisoning in which the brain is exalted, depressed, narcotized and changed, and precipitated into states of partial insanity

The use of these drugs may be a symptom and point to some degeneration and arrested development, attended with irritation and exhaustion for which these drugs bring relief In all cases they have no food element to build up the brain, but by irritation and depression break up and tear down the higher processes of cell and brain activity When such cases come into court and the soundness and unsoundness of certain acts are to be examined, then these general facts appear and form the basis for a wider and more exhaustive study

The medical witness should never try to draw dividing lines as to where mental health and disease join He should assume justly that from certain causes certain effects are always to be expected That continuous use of drugs for their effects is always injurious, and no one can be rational and sound who poisons his brain with narcotics Also, that each case is a law to itself, and from the facts and conditions clear, general conclusions can be affirmed that will bear the test of examination and study Forensically, the question of responsibility determines the measure of punishment, and here the judgment of the physician should be clear, independent and unbiased

---

THE POST-ACTIVE TREATMENT OF NARCOTIC HABITUÉS

Read in the Section on Neurology and Medical Jurisprudence at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md , May 7 10, 1895

J B MATTISON, M D
MEDICAL DIRECTOR BROOKLYN HOME FOR HABITUES
BROOKLYN

Very largely among the laity, and, to no small extent, in the profession, an opinion obtains that narcotic inebriety is a cureless disease My experience, covering a quarter century and compassing the history and treatment of many hundred cases, has convinced me that this opinion is a mistaken one, and in two papers, "The Curability of Opium Addiction," *Journal of Inebriety*, 1885, and "The Curability of Narcotic Inebriety," *Cleveland Medical Journal*, 1893, cases were cited in proof

Years ago, the opinion was advanced that 30 per cent of proper cases, properly treated, resulted in permanent recovery I am no less optimistic now than then, and when the value of a certain post-active regime in the treatment of the disease is fully appreciated, and is insisted on and persisted in as its importance demands, my optimism will assume more generous proportions, and a blot on the scutcheon of professional success along this line will be largely removed

It is not surprising that this non-hopeful feeling concerning a continued good getting on after quitting a long-used narcotic should so largely be held The common idea that the habitual user of opium, chloral or cocain is simply the victim of his own vicious indulgence, implies a damaged morale on the part of the patient that militates strongly against any lasting good from a strictly therapeutic endeavor The somatic factor in causation being denied, the crippled condition being deemed due to impaired psychique rather than physique, and these unfortunates being looked upon as moral lepers, who, having knowingly "sown the wind" must "reap the whirlwind," that measure of sympathetic succor which would bring to them what the resources of modern medicine can surely extend is withheld them, and they are given over by their pessimistic commiserators to a bondage binding for life

I have held and still hold that this largely prevalent idea as to the etiology of narcotic inebriety—in the immense majority of patients—among the better class (and I assert and insist upon well-marked class distinction in these cases) is a mistaken one, *vide* "The Ethics of Opium Habitués," two papers, *Brooklyn Medical Journal* and *Medical and Surgical Reporter*, 1888, that a physical necessity, not a moral obliquity, is the great genetic factor, and that a full recognition of this fact, in both active and post-active treatment of this disease is absolutely essential to a large and lasting success And, *en passant*, it is a pleasure to express my belief that the trend of professional opinion is growing along this line, as regards both alcoholism and morphinism, the two forms of inebriety that to-day most menace private and public weal

The advance of scientific medicine during the last half decade, in the treatment of the last named neurosis, has been such as to warrant a statement in 1893 before the Pan-American Medical Congress that, at no previous time had it been so simple, so satisfactory and so successful Enlarged experience has not lessened this opinion, in fact, the modern and humane treatment of the morphin disease, which so specially attaches to the Mattison method, is securing increased and increasing recognition, appreciation and application, all of which I make bold to say—at the risk of being deemed an egotist—the merit of the method unquestionably deserves

But while we have reason to felicitate ourselves on therapeutic progress in this field, touching the question of acute cure we are still face to face with the unsettled, because largely unsuccessful, question of what may be termed chronic cure To the solving of this problem our best effort may well be directed, and it is the purpose of this paper to present certain facts, the outcome of an experience not small, and to commend such details of post-active treatment as will tend in most measure to secure a lasting success

As stated in a paper, "Morphinism in Medical Men," presented this ASSOCIATION last year, the majority of those who honor me with their care belong to our profession As fellow-members of a noble guild it is quite natural that we who have not fallen under the poppy blight should feel a more than common concern in their well-being, and, taking them as a class—though the same danger pertains to most ex-habitués—it may be said that three things imperil the permanence of their cure They are overwork, rum and tobacco

In laying special stress on these, it need scarcely be said that the full repair of all health infractions—brawn or brain—that stood in causative relation to the initial narcotic using, is a *sine qua non* in doing permanent good But granting that full repair, and that nothing remains save the entail of a narcotic abuse, many cases present in which the risk of failure pertains to one or other or all of the three causes cited

Regarding the first of these, overwork, one can easily understand why the varied and exacting demands of an active medical life should make it take first rank among causes effecting an untoward result And in direct ratio to a premature resuming of the doctor's toil, is the peril of his again falling victim to the poppy need

It may seem strange that a medical man, who, above all others, should know the disturbing effect of a long-used narcotic on functional well-being of mind and body, does not appreciate the danger of too soon resuming work Such, however, is the fact Of course, cases occur where, from conditions beyond control, despite a full realization of this risk it must needs be taken, but too often the lack of good judgment in not recognizing the great truth that a nervous system, battered and bruised for years by narcotic excess, will not in as many weeks or months regain its pristine status, is the main reason for failure in the good work—be it never so well begun History has repeated itself so often along this line that I emphasize this danger, and warn against it with all the energy at my command

Alcohol lessens greatly the hope of permanent cure *No ex-narcotic habitué is safe who uses rum in any form* The question of kind or quality—mistakenly held by some—is of no import Pure or impure, beer or brandy, wine or whisky, the risk impends, for it is the alcohol that makes the mischief Years ago that opinion was reached and each year has but added to this belief And this prompts me to say that I think the use of alcoholic stimulants in the active treatment of narcotic inebriety is needless and dangerous Needless, because success can be secured without them, and dangerous—doubly so—because they retard acute recovery and tend to create a need for continued taking which makes much less hopeful the outlook for continuous good getting on I am well aware that the opposite idea, both in active and post-active treatment, is held by some—notably among Germans—but, guided by the lamp of my own experience, I am bound to assert my opinion absolutely and everlastingly

Tobacco endangers recovery This belief, though more recently arrived at, has become just as fixed as that regarding alcohol, so much so, in fact, that no applicant for my care is accepted unless he or she will agree to abandon the weed This, it may be, is counter to the common view, but testimony and observation, reasoning and experience have brought me to this precept and practice

If it be asked why such a radical idea governs my counsel and care in these cases, one broad, general answer is given—this Large and enlarging experience has convinced me, beyond all question, that the use of alcohol and tobacco by convalescents of this class tends, by lowering nerve tone, special and general, to prevent that return to pristine integrity of health which makes it most largely proof against recurrence of a narcotic need

While insisting on the eminent importance of this triple abstaining during the post-active régime, care must be taken to continue all those factors which make for good during the early abstinence time It goes without saying that favoring environment, freedom from worry, care along secretory and excretory lines, and a tonic régime, all play a large part in repairing ravages of narcotic abuse, and must be continued, if need be, for months or years, and when to these are added the special causes that make less vulnerable a post-narcotic state, we shall surely note a lasting betterment in patients' future and in professional good repute

Prospect Place, near Prospect Park

REFLEX NEUROSES

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association, at Baltimore Md, May 7-10, 1895

BY JAMES K KING, M D, PH D
MEDICAL SUPERINTENDENT, GLEN SPRINGS SANITARIUM
WATKINS, N Y

The intricate and complex nature of reflex nervous diseases and the difficulties in the way of studying any pathologic changes that may exist, make them the most complicated of any we have to treat The long, patient and exhaustive line of experiments, tending to unfold the reflex nerve phenomena, has thrown much light on this subject You are all familiar with these scientific investigations When we pass from the physiologic to the pathologic field of investigation we find it still more unfruitful in clearing up our doubts, just as all morbid processes are more difficult to unravel than purely physiologic ones

When the reflex stimulation is increased, there is an increase of the peripheral irritation somewhere, but where, is the difficult question to settle Reflex irritation means often an increase in the irritability of the afferent or efferent tract It may mean an increased irritability of the gray matter of the brain or spinal cord, or it may mean that the inhibitory influence of the cerebrum is more or less diminished, or, lastly, it may indicate that the sensory tracts and psychic elements are increased. Frequently, in a still more complex manner, the irritation is transmitted from the sympathetic system to the sensory tracts of the cerebro spinal.

If we study carefully the sympathetic nerves distributed to the pelvic viscera and trace them back to the several ganglia situated at and below the bifurcation of the aorta, following these tracts up the spinal cord and the ramifications to the various organs, we can readily see how intimate and frequent these reflex disturbances are. The urinary and reproductive organs and the rectum are particularly subject to irritations that travel up these sympathetic tracts and cause functional disturbances in other organs. But this is true of all organs and it is not yet possible to understand how an ulcer in the rectum, a contracted cervix, disease in the middle ear or errors of refraction can disturb the stomach, but we know from clinical experience that it is so. We can not yet see how certain abnormal conditions of the stomach and liver, variations beyond our ability to differentiate, can, in one instance, cause pain or intermittent pulse, or palpitation of the heart, at other times a variety of headaches, and at other times psychic phenomena, such as depression and melancholia. We can not explain how anything very cold taken into the stomach will cause a severe lancinating pain in the left side of the head. Perhaps it is due to sudden contraction of the blood vessels excited by reflex action.

Many reflex irritations are beyond our knowledge of the line of reflex phenomena. When I was in the Rotunda Hospital we were in the habit of using hypodermics of ergot to control uterine hemorrhage. The effect was too immediate and pronounced to be due to any absorption and physiologic action of the ergot. We concluded that the effect must be due to reflex irritation. By experiments we found that hypodermics of chloroform or cold water would produce the same results.

The number, extent and variety of reflex nervous disturbances are so great, and the uniformity as to their classification so uncertain, that it seems to me desirable at the beginning of this paper that we define as clearly as possible what nervous diseases properly belong to the class grouped under the heading, "reflex neuroses."

Dr. H. Gradle, of Chicago, has contributed to this society a very valuable paper on the study of reflex neuroses having their origin in abnormalities of the structure of the eye. He has also referred to other reflex disturbances. Many others have aided greatly toward the solution of vexed questions referring to these functional nervous diseases.

There has been and still is entertained, by distinguished neurologists and other special workers, a wide difference of opinion in reference to the nature and extent of reflex nervous phenomena, and as to the propriety of including certain nervous diseases in this class. Among those who have considered that many nervous diseases, including certain forms of hysteria, epilepsy and insanity are due to reflex excitement, we need only mention a few names like those of Brown-Séquard, Sayre, Neiden, Hack, Stevens and others. An opposite opinion has been held, as we are all aware, by able men like Skene, Jaccoud, Romberg, Mitchell, Gray and others. This wide difference of opinion must be due to a want of definiteness of terms and classification, and the results of different experiences in the treatment of diseases. We will be able to clear up some of the difficulties if we make a careful study of the causes of nervous diseases. Malaria, diphtheria, tuberculosis and a long line of diseases are due to a definite cause, a definite germ. Not so with nervous diseases, especially the class we are discussing. Take for instance, the mooted one, epilepsy. It is sometimes due to brain disease, sometimes to brain pressure, sometimes to sensitive cicatrices on the cutaneous surface, sometimes to dyspepsia—more times to causes beyond our ken. We can all bring forward cases to prove that epilepsy has been due to the nerve storms excited by these various causes.

Insanity, with its protean forms of expression, is due to a far greater variety of causes than epilepsy, and is alike difficult to classify. Hysteria, as mysterious and manifold in its causes and expressions, as that weird and popular American disease, neurasthenia, and often associated with it, is subject to the same indefinite laws of classification.

Headaches are due to even a greater variety of causes than any other infirmity we are called upon to treat, frequently reflex and yet by no means always so. We might multiply illustrations indefinitely, but it is not necessary.

Now if we recognize in the first place the law laid down by Wilkes governing functional nervous diseases, much of the diversity of opinion will be cleared up. It is in these words: "Moreover, it is undoubtedly true that there is not a single organic disease of the nervous system which may not be simulated by a functional and curable one."

Now if we recognize in the second place what was indicated in our reference to epilepsy, insanity, hysteria and headaches, viz., that functional nervous diseases are due to a great variety of causes, the line of separation between the different views of neurologists will grow much less distinct. The recognition of these two fundamental facts or laws in the investigation of functional nervous diseases will help us greatly. We are thus enabled to explain how sclerosis, paralysis, locomotor ataxia, etc., also paresis, softening of the brain and various types of insanity have been cured, simply because we have been mistaken in our diagnosis.

When Dr. D. R. Brower was asked what he thought of the success of the man who had cured so many cases of locomotor ataxia, he wisely remarked that he thought he had made a mistake in his diagnosis. A man was sent to me from a neighboring city several years ago, with acute softening of the brain. He recovered and is at work now. How did it happen? That was a mistake in diagnosis.

When we find so much difference of opinion as to the number of nervous diseases that should be included in the class entitled, "reflex neuroses,’ our simplest way to reconcile the discordant elements is to attribute the difficulty to defective diagnosis. Because one man has a case of epilepsy and cures it by correcting some error of refraction in the eyes, or by the removal of a tumor, or by the correction of some serious trouble in the alimentary tract, or by the removal of diseased ovaries or tubes, and thus places it in the class of reflex neuroses, there is no reason to find fault with the next man who has a case of epilepsy not due to any of these troubles, but to some serious central lesion which excludes it from the class of nervous diseases we are considering

It is asserted by some neurologists that hysteria is due to central or psychic origin rather than peripheral or reflex Hysterical manifestations may be due either to organic or functional disease They may be psychic or reflex, central or peripheral in their origin

I had a case under my care several years ago Her trouble was diagnosed by several of the most noted neurologists of Canada and this country as hysteria The diagnosis seemed to me correct She grew gradually worse and after some years died The autopsy proved the trouble to be tubercular meningitis Often there is some point of peripheral irritation, as the uterus, ovaries, rectum, etc *A reflex neurosis is developed* and it takes on an hysterical type A psychic element enters in by association of ideas, all the symptoms are greatly magnified and all the extravagant adjectives in the vocabulary are used to describe the symptoms These cases are purely reflex But we meet with grave cases at times

Last year a case was sent me, with a nurse specially trained for hysterical cases The disease had been diagnosed by four of the best men in New York city and New Jersey as hysteria All the external manifestations were those of hysteria Many of her symptoms, such as vomiting, could be controlled by severe discipline I soon began to notice symptoms that pointed to organic derangement of the bowels Some obstruction manifested itself and I diagnosed the trouble as malignant, counsel agreed with me I sent for her physicians and they agreed Operation revealed the case absolutely hopeless Now this was undoubtedly a case of mistaken diagnosis, as far as the cause was concerned, but the symptoms were those of hysteria

Headaches are, in forty-nine cases out of fifty, due to peripheral origin in the eye, the ear, the stomach, the bowels, the liver, the generative organs or at some other point—a reflex neurosis—a functional disease, but the fiftieth case, some one will be unfortunate enough to have, will be due to and part of some grave lesion as a brain tumor, a depressed internal table resulting from a fall or blow, or organic brain disease Headaches are due to so many reflex irritations that it is often difficult to diagnose them correctly and more difficult sometimes to cure them We often find a headache the result of more than a single reflex irritation A headache may be due to derangement of the stomach and liver, the liver and bowels, the stomach and uterine disturbance, or to any of these and some error in refraction To cure the headache it is necessary to correct all these troubles The success of the physician depends on his ability to locate the point or points from which the reflex irritation starts

One writer attempts to prove that reflex irritations are of very rare occurrence and that uterine and ovarian diseases do not produce, *per se*, reflex neuroses, but do so for instance, by indirectly disturbing nutrition and that in turn produces headache and other nervous disturbances Clinical experience every day disproves this untenable theory

Three years ago I had a most interesting and instructive case sent me from the East, a lady who had suffered from violent neuralgic headaches which had been gradually growing worse for years, until large doses of stimulants and narcotics were the only source of relief She was 55 years old All approved remedies, local applications, hygienic methods and general tonics were tried for six months At the end of this period the headaches, notwithstanding her general health was much improved, were no better but rather worse The case seemed almost hopeless She had quite a deep unilateral cervical laceration, but as she had passed the climacteric there seemed little to be gained from any operative interference Having exhausted all other means likely to afford relief, I determined to try this last chance The operation was done with great care in the adaptation of the opposing surfaces Union was perfect Two weeks after the operation she began to improve There were few interruptions in the progress of the case. The *headaches disappeared, the sleep returned, she gained* all the flesh she had lost and the restless nervousness entirely disappeared This was undoubtedly a reflex headache—a reflex neurosis I might quote from my case-book a number of similar cases, but this will suffice to illustrate this variety of reflex irritation

Nutritive disturbances are often due directly to reflex disturbances I remember a case sent to me by a physician in Cincinnati She was 38 years old, quite regular in all her functions, but was suffering from anemia and neurasthenia, the latter dependent on the defective nutrition I tried for three months to improve her general health, her nutrition, and build up her nervous system At the end of this time I could not see much improvement The only symptom she had of any uterine disturbance was a slight non-irritating leucorrhea I had spoken of an examination before, but she refused, and as there was so little indication of any disease I did not think it important to insist upon it The slight leucorrhea could be entirely accounted for by her weakened condition I determined now to know the exact nature of the trouble I found an extensive erosion, such as would formerly have been termed ulceration, covering the entire cervix, associated with endometritis The uterine canal was three and one-half inches long She was put upon appropriate treatment and the stomach symptoms were soon corrected She improved in flesh and color rapidly and the nervous symptoms disappeared This was not a case of nervous dyspepsia as had been supposed, but a case of reflex neurosis

Chorea is a Reflex Neurosis —In chorea we find many cases due to embolism of the corpus striatum or thalamus opticus, and other serious lesions, and yet every practitioner knows that many cases—the majority of cases—of chorea from their onset and sudden disappearance are purely functional Dr H C Wood has made it very clear, by showing that the majority of cases are at first functional and due to some reflex irritation, as nutritive changes, and are cured in this stage, but if they continue there is a change of structure and they become organic diseases Clinical experience is rich in illustration of these cases Dr Osler does not agree, as I am aware, with these views

Reflex Cardiac Neuroses —The everyday reflex disturbances of the heart, arising from the stomach and other organs, are too familiar to refer to These reflex irritations may increase in severity until they simulate one of the most painful and serious diseases of the heart, or, in fact, of the body I will only recite one case to illustrate this statement

Not long ago a lady was sent to me from central

New York with the diagnosis of angina pectoris She was 32 years of age and the mother of three children The youngest child was 3 years old The trouble with the heart had existed for one year, but had only been severe for two months, and the attacks had become more frequent also She had been seen by a number of the best New York physicians and all pronounced it a very grave case and liable to terminate fatally at any time After considerable correspondence she came with her family physician That night she had one of her paroxysms and we all thought she would die before morning, sedatives and stimulants tided her over this attack After a few days of rest and quiet, I began to consider the question of treatment She had had the most skilful and scientific treatment Nothing was to be expected from remedies, so I tried to see what I could find that might prove to be a source of irritation She had several rectal fissures and a good deal of tenderness—there was a deep bilateral laceration of the cervix and the perineum was torn back of the sphincter ani I felt hopeful that the correction of these conditions might prove beneficial

As soon as she was in a reasonbly good condition, which was not until she had passed through three attacks in each of which we expected she would die, the plastic surgery was done on the cervix and soon after she began to improve She had several lighter paroxysms but no severe ones The next step was to repair the perineum and correct the trouble with the rectum After these were done she had no more attacks, but made an excellent recovery

Hysteria a Reflex Neurosis—I have referred to this subject in a general way Two years ago a gentleman came under my care who had been distressingly ill for six years He had been seen by many physicians in Europe and later in this country He suffered with agonizing pains in his stomach and shoulders For these pains and the wretched nervousness he had been given anodynes freely All the physicians who saw him pronounced his trouble hysteria These paroxysms of pain and nervousness would come on and grow more and more severe for from twelve to twenty-four hours, when morphin and hot applications would quiet them His family had become quite estranged from all sympathetic relations, because they felt that these were hysterical manifestations and might be controlled I could find no pathologic derangement except in the rectum There I found several ulcers and fissures and marked prolapsus I corrected these troubles and in about three weeks he was greatly improved and slept well I kept him on a hygienic course of treatment for two months and he entirely recovered

Insanity as a Reflex Neurosis—I have had so many cases of insanity in the last ten years, illustrating the influence of reflex irritation producing these mental disturbances, that it is not easy to make a brief selection I have thought well to draw from other sources also, to give more emphasis to these assertions

Dr Frank Churchill reports an interesting case in New York of hystero-neurosis and melancholia, cured by trachelorrhaphy

Dr Sprattling, of New Jersey, reports a case of rare and unusual interest, showing the dependence of nervous and mental symptoms on the condition of the other organs

A patient 28 years old, suffering from hallucinations of a violent type A large quantity of *débris* was removed from one ear of which he complained a good deal The patient soon after entirely recovered his health and remained free from the hallucinations

Some years ago I had a case of melancholia with delusions, due to a contracted cervical canal Dilatation cured the delusions

In the *Medical Record* May 2, 1891, Lawson Tait reports a case of periodic insanity with marked homicidal tendency, cured by the removal of the ovaries and tubes

Drs Jewell and Mosher report cases of insanity cured by the removal of impacted feces I have had similar cases

In 1889 I had a case sent me from New York suffering from melancholia The patient was 43 years of age and had been complaining for some time She had been in the care of two excellent gynecologists and was in good condition in this respect, with the exception of a small bilateral laceration of the cervix I advised douches and paid no more attention to this trouble She was kept on a course of hygienic treatment, and all remedies and appliances that would correct the digestion, improve the circulation, tone up the system and contribute to the improvement of the mental condition were employed Every method and plan of treatment I could devise, with the assistance of good counsel, proved ineffectual, and at the end of two years of treatment she was better in general health, but the melancholia had assumed a severer type and she was delirious and was developing a suicidal tendency Having tried everything else, I determined to repair the lacerated cervix, notwithstanding several of our most noted gynecologists said that it produced no reflex symptoms After considerable consultation I did a trachelorrhaphy with unusual care in adaptation She was so wild that it was impossible to keep her still, but we got a fine union and within three weeks we began to see an improvement in the mental symptoms The patient entirely recovered and is well to day This, gentlemen, was a case of reflex neurosis

---

EARLY RECOGNITION AND MANAGEMENT OF THE MENTALLY DISTURBED

Read in the Section on Neurology and Medical Jurisprudence, at the Forty sixth Annual Meeting of the American Medical Association held at Baltimore Md May 7 10 1895

BY W S WATSON, M D
RIVERVIEW HOME SANITARIUM, FISHKILL-ON HUDSON
NEW YORK

Nothing has so much tended to confuse, distort and implant the supposed need of harshness in the management of the insane as our forgetfulness of the infirmities of the human mind It was assumed that a broad and unmistakable line of separation marked the difference between the sane and the insane, that detection was, therefore, a matter of ease, while the facts are that a mere mist, a veil separates, and a something that is easily broken through There is a certain tendency to disorder incident to every mind as regards strength, harmony and development

Do not the eccentricities, the proneness to vice and crime, the indulgence of the passions, the weaknesses of life demonstrate the inherent tendency to mental disorders? As our body is diversified with counterbalancing functions, and in its delicacy and completeness of arrangement is constantly liable to disease and in fact engenders within itself the elements of disease, vastly greater is the mind likely to be diseased, poised as it is in a sensitive balance and more complex in its structure We know that insanity is a disease due to some abnormal condition of the brain The causes are various, and it is practically impossible to give a definition that will embrace all the phenomena

A well-balanced mind is like a sound body, in health we hardly realize that we have a heart, a stomach or liver It is thus with our minds if all goes well and our brain is healthy, our thoughts go out and we scarcely realize that we have a mind until there comes into our lives some disturbing element, some cause for excessive thought, a something that gives us mental pain—we may, ere we know it, realize that we have mental disease It is difficult to recognize the borderland, to fix the line between sanity and insanity, between health and disease, since they so intimately blend into each other Before the grosser lesions of well-marked insanity there are often defects in nutrition long before structural changes take place The time when the most good can be done is during the nutritive disturbances which precede structural or organic changes

As to the actual curability of the insane but little can be said, therefore, it is all important that active measures be taken before a well-defined mental break-up takes place The brain, the controlling center, is subject to exhausting influences to a much greater extent than any other organ of the body An overtaxed brain does not recuperate so readily as other organs to perform its functions, but if from any cause or strain sleep does not follow, rapid exhaustion succeeds, together with hyperemia

Brain-cell nutrition takes place principally during sleep Anything that interferes with proper periods of rest and sleep directly interferes with the nutritive plasma passing from the vessels to the cells and derangement of the intimate connections between the nervous and vascular systems will ensue, producing grave disturbances of the nervous system, which are followed, sooner or later, by insanity We shall not attempt to go into any description of the elementary disturbances or morbid processes, as these are matters treated of in our text-books on psychologic medicines, and such description would extend this paper far beyond its intended scope

Our object is to urge upon the profession the early recognition and repression of the initial symptoms, believing that thousands are needlessly declared to be insane annually and thus are placed under restraint in our asylums without due regard to the type or degree of mental disturbance

It is lamentably true that an asylum is regarded as a necessity to any and every one becoming wholly, or in part, deprived of reason, a public feeling which is largely due to a belief that asylum physicians only are qualified to understand and care for this unfortunate class While we thoroughly believe in our insane asylums and of there being a public necessity for the detention and care of the violent class, we do not believe it is necessary nor is it proper to hurry off to an asylum and associate a slightly disturbed individual, a case of melancholia or reasoning mania, with the worst types of insanity where all is repulsive What can be more humiliating to a man who has any intelligence left than to be made subservient to an ignorant attendant and his abuses, a condition that does and always will exist, to a greater or less extent, where hundreds are congregated together With all due respect to asylum physicians, many of whom are able men and well qualified for the work assigned them, to insinuate that no others are fitted by other mental training for the recognition of the early symptoms of insanity is erroneous and a palpable wrong, kept alive by a few for their own aggrandizement Many of the most eminent alienists of modern times were never connected in a professional way with an insane asylum Who has done more to advance the interests of the insane than Dr Rush? Griesinger, once a leading authority the world over, was never a physician to an insane asylum, nor was Clymer, Seguin, Spitzka, Beard, Mitchel, Jewell and many others of equal renown and assiduous as workers

There is nothing mysterious or especially obscure about diseased conditions of the brain that require asylum observation only We recognize the fact that our asylums afford exceptional opportunities for the study of the degenerate types, while we concede this much, we are confident that the general practitioner and the specialist outside of the asylum are the ones who are called upon to intercept and save from the madhouse It is to them that people go to for advice and it is their duty to do the best possible thing at the earliest possible moment, yea, when the first symptom shows itself We believe it an injustice and deleterious to mild forms of mental disturbances, cases capable of reasoning logically regarding the everyday affairs of life, those yet capable of controlling themselves, slightly melancholic cases, acute mania, restricted monomania, hypochondriacs, all of which fare much better outside of asylums than in them, as a rule

We do not want to be understood as favoring no treatment or watching of such types, on the contrary, we favor the most active measures, such as can only be secured in private homes and institutions, and the placing of these persons among sensible people for companionship, with refined educated persons for attendants

The association of a partially insane person, day after day, month after month, with others similarly or worse afflicted, restrained from contact with people of well-balanced minds, is fraught with no possible good Any medical man having had to do with the mentally disturbed, knows that a very large proportion of such cases have physical ailments that are exciting causes, which only need the practical attention of one conversant with such conditions, one skilled more or less in mental aberrations and their causes, pathologic conditions, etc

We believe it is the province of medical science to arrest in the incipient stage many brain disorders, heretofore considered incurable, with the aid of modern methods if attention is early given

Disordered function surely means organic destruction sooner or later Fully 80 per cent of the insane cases may be cured if treated early and properly, while scarcely 15 per cent committed to the great asylums of our land recover

We have said that the brain is peculiarly liable to disorder through disturbance of circulation, in cerebral inflammation, there is first observed an unnatural exaltation of nervous force with intolerance of light and sounds, a general hyperemia and the capillaries are filled, we may also have a general or local hyperemia of a vasomotor origin from prolonged mental work or excessive tension of an emotional character, gastro intestinal or pressure from disease of the blood vessels themselves or an encroachment upon them by morbid growths, etc What are the indications? What will follow if active measures are not taken? First, the congested condition—the hyperemia of the brain must be relieved and promptly, if we hope to keep our patient from the madhouse or from general paresis Long continued congestion will, sooner or later, produce organic changes, if there be any physical or mechanical reason for the unequal circulation, as gastro intestinal sluggishness, we would begin by giving a free mercurial purge, one that will unload the primæ viæ, it is not at all an uncommon thing to find a large amount of accumulations and in character of the worst We have had cases where it would seem that there had not been a free evacuation possibly in weeks, in which cases enemas and purgatives have been given for days, with copious discharges of the most offensive character possible, after the purgatives have been continued until from the character of the evacuation we were sure it had not been long retained or was poisonous, there has been a marked change in the patient following immediately these thorough unloadings, in many instances there would seem to be little or no mental disturbances left Then, again, it is highly important that we eliminate the excess of uric acid from the system

A lithemic condition is an important factor in many of the mentally disturbed, in fact, in nearly all cases there is lithemia If the hyperemia be due to prolonged overwork or business cares it must be stopped at once, and such means used as will procure rest and act upon the weakened vessels of the brain When the blood-vessels of the brain become dilated, there is a loss of tonicity For such weakened conditions we have in electricity almost a certain means of restoring tone to the vessels, thereby improving the nutritive conditions, the constant or galvanic current is the one used, and in mild doses, applying the positive pole by means of a crown electrode over a well moistened towel that has been wrapped about the head, the negative sponge electrode to the epigastric region or under the two feet, using 3 or 4 milliampères, with an occasional interruption of current, we believe is the best possible means We would also give ergot in moderate sized doses daily, with the expectation of aiding the electricity in overcoming the dilatation of the blood-vessels from its well known powers over such conditions If the congestive conditions are dependent upon a purely mental condition, one of nerve strain, of tension from worry or fixed ideas, it is all important that the mind be put at ease and the brain have rest

It is well known that the influence of the mind upon the body is wonderful for good or bad, as the case may be, in health, it may exalt functional conditions or suspend them, the mind is all-powerful over the nervous system and may excite or depress, may stimulate or paralyze the processes of nutrition or secretion even unto death, and in disease, the mind may restore funtions, enervate the vasomotor and sensory nerves, thus throwing off disease

Sir John Forbes gave it as his opinion long ago, that the curative powers of nature were sufficient to explain all the triumphs of homeopathy We believe that more may be added, it is not to the curative powers of nature alone that the triumphs of homeopathy may be ascribed, but rather that of suggestive therapeutics, with like certainty may the so called miraculous healings be placed to the credit of psychic influence rather than any supernatural power No one disputes that the everyday physician's manner and mode of addressing his patients inspires confidence and has a great deal to do with the recovery many times

The celebrated Dr Rush gives testimony to the value of inspiring confidence, and often attributed the cure to vigorous concurrence of the will with the action of the drug used The power of the will in resisting disease, aside from the influence of imagination or concentration of the mind is unquestionable Since this is a recognized fact in medicine, are we not called upon as physicians and philanthropists to get control of the mind to such a degree as to carry it in the right direction if we can To do so we must raise psycho therapeutics to the plane of a fixed science, to do this a thorough test must be made of the laws and conditions governing the phenomena which heretofore has been enshrouded in obscurity, the hostility and indifference to investigation and acceptance by the medical profession generally is a difficulty to be overcome and will only be overcome by the presentation of facts

Not only is the prejudice of the medical profession to be overcome, but also the peculiar whims of the laity, as there is an opinion current that one part of the human family is subject to the other, that we are likely at any moment, unawares, to be hypnotized and brought under the evil influence of even the most debased The general public has enough information or misinformation regarding the phenomena of the so called hypnotism, that in reality it knows nothing and has its mind filled with imaginations as to the great and dreadful possibilities of one in possession of the power to hypnotize Thousands are worked up to the belief that all the wrongs of life are due to the evil influence of some one, the influence that somebody has over them, and if they commit an evil deed that they are not responsible, or that some one else should be held responsible for their acts, husbands accuse their wives of being under the power of some one, the wife claims that so and-so has her husband under control, even some of our courts have ruled in favor of this mysterious influence, setting as they have the minds of the general public aflame This belief has, indeed, assumed very serious proportions We read almost daily of some dreadful deed having been committed while under some external influence We feel warranted in saying that there is not a word of truth in the claims of these people—persons who assume to ascribe their wrong deeds to the mysterious power of somebody else We do feel that the medical profession is called upon to set the minds of the people at rest by placing hypnotism where it belongs—in the hands of the medical profession only That there is much good to come from this psychic influence there is, we think, no longer room for doubt, as regards harm, that will be just in proportion to the intelligence that goes with it Let the people be educated to know that there is no hypnosis without acquiescence or cooperation, then will the idea of evil influence subside and claims of that character will cease Public exhibitions of hypnotism should not be tolerated, lay papers should have nothing to do with disseminating the false impressions that have brought distress and ruin to hundreds. Stringent legislation against public exhibitions should be enforced. It is unquestionably true that psychotherapeutics provide a means by which a change of condition and many times a cure can be effected, and that its best field of action is diseases of the nervous system, before organic changes have taken place. Hypnotism is effective in disturbances due to imagination, fixed notions; it is a well-known fact that long and continuous thought is ruinous. If we have in hypnotism a means of directing the mind into healthful channels, away from worry, we are justifiable in bringing it into practical use even though it may be true that only a small proportion of persons are susceptible; and notwithstanding there may be possible danger attending the use of this agent, danger is common to many others. If we were to discard from our therapeutics everything that can be dangerous to life, we would have but little that is good left. Our personal experience is too limited to be of real value as to the weakening effect that hypnosis may have upon the mind of the hypnotized. We do believe that such fears are unfounded; we have read the works of most of the ablest writes, those who have treated thousands of cases, in which they do not report a single instance of harm to the mind or nervous system. We do believe, and yet it is inexplainable, that the hypnotizer subjects himself to the loss of some vitalizing principle in the process of hypnotizing that exhausts more or less rapidly. We have, after spending an hour or more and when with two or more persons, felt decidedly exhausted, and when continued for weeks it was attended with loss of energy and followed by insomnia; hence we believe the danger attending the use of hypnotism is principally to the operator.

SOME NON-MEDICINAL SUGGESTIONS IN THE THERAPEUTICS OF EPILEPSY.

Read in the Section on Neurology and Medical Jurisprudence at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY S. J. FORT, M.D.

ELLICOTT CITY, MD.

Interest in the manner of how not to give medicine in the treatment of disease is daily increasing, and there is, probably, no domain of morbid condition to which human nature has fallen heir that repays non-medicinal medicine more rapidly and well than the so-called diseases of the nervous system, and while epilepsy may perhaps not be a disease pure and simple, for convenience of discussion, it may still remain under that caption.

It may be well to state also, that all medicine must not be condemned because in the past the stomachs of our forefathers or even nearer relations, perhaps those bearing the names which appear upon our own visiting lists, have been dosed *ad nauseam* with the long list of drugs in our pharmacopœia; this is no reason for throwing aside these valuable aids to nature's recovery; it is simply an argument for a more thorough diagnosis, a more intimate acquaintance with pathologic conditions, and a more consistent belief in nature herself and the patent indications for remedies outside of lists of drugs.

I have been more and more forcibly impressed with the advantage of several therapeutic resources not usually mentioned by modern authors who have written upon epilepsy, in the treatment of this disease. I wish I could begin my suggestions by citing a long list of cures, but you are all familiar with the general intractable condition of the disease and, I take it, are here with the idea of combining our present knowledge of its treatment, and, if not curing at least alleviating, in a greater measure, the many poor sufferers from the spasm proper and the still further awful depredations upon the mentality.

First, I would place in importance the sanitarium, asylum, colony or whatever plan will isolate the patient from the outside world and place him or her in a microcosm of their own, *sans* temptations, and where the physician will be the inspiring genius. I do not believe that any case of epilepsy, be it *petit* or *grand mal*, can be successfully treated when the patient is at home, because medicine alone will effect but few cures, and a rational home where a rational modern scheme of treatment of epilepsy can be pursued is as rare as an egg of the great auk. This is not alone from the fact that few homes have gymnasiums, bathing facilities and hygienic surroundings; the entire atmosphere and environment of the epileptic must be changed; he must be brought under a systematic life, the better to combat the irregular nerve explosions; in other words, he must undergo a species of training something similar to that of the athlete, with one difference, that it must be lifelong with the epileptic.

Arguments from a utilitarian standpoint might be adduced to show why the epileptic should be isolated from the world, but this paper has to deal simply with the fact from a therapeutic standpoint; a standpoint which says that it is best for the patient to be thus brought under the direct control of his physician, which will give him a greater chance of recovery, and if not recovery, a mitigation of the spasms and at least hold stationary what modicum of mentality the patient may have. The ideal home of the epileptic must be equipped with a gymnasium and a system of baths, especially the so-called "rain bath" which is perhaps the best and only one needed; the value of the Turkish or Russian baths has not yet been worked out. Next in importance as additional resources are methods of employment, such as all the light trades, broom and brush making, carpet weaving, basket making, shoe making, mattress making, wire working, etc., beside, if possible, the manifold duties of the farm. An epileptic who is interested and employed will have fewer spasms, all things being equal, than an unemployed case whose time is principally taken up in contemplation of his unfortunate and well-nigh hopeless condition, albeit, he may be under medicinal treatment, and the former case will suffer less from his spasms than will the latter.

While not claiming originality in the above suggestions, it appears to me that the truths of the propositions laid down so far, merit the earnest attention not only of this Section but of the entire ASSOCIATION; that an earnest and combined effort may be made in behalf of the establishment of more colonies like those of New York, Ohio and Illinois. That every State must eventually assume charge of its epileptics, certainly its poor, is I think incontrovertible and the sooner the better. To return—the next important resource is not altogether non-therapeutic, inasmuch as some materia medicas have now a chapter or two on food, and very much can be done for the epileptic by carefully mapping out for him his daily bread and butter Nearly every epileptic who comes under the observation of the sanitarium or asylum officer is gross in proportion and appearance, and will be found to have a voracious appetite, or, if the appetite is capricious, it is made so by the foul condition of his alimentary tract, and the careful pampering of his abnormal appetite by his guardians, "the poor fellow wants it, and he ought to have it because he has so little enjoyment," a fallacious but extremely powerful argument so long as the patient is at home

Coincident with regularity in evacuations of the bowels and free flushings of the kidneys, is noticed a striking diminution in the frequency and severity of the spasms, and with the disappearance of the unhealthy development of adipose tissue and the general clearing up of the symptoms of over feeding, is seen usually a brightening up mentally and all this without the use of bromids or other medicines beside cathartics and the free use of water, internally and externally

In formulating the diet of our epileptic patients we have to consider those of different age and those of different habits I think, if it is possible to oversee the bill of fare, week in and week out, for years at a time, there are many epileptics who may be permitted nearly everything that any one else eats, excluding only such articles of food as are known to be indigestible and guarding most carefully against overfeeding We shall meet some cases who can not eat certain articles of food without danger of a spasm —for instance, I have under my care a child nearly 13 years old who has not had a spasm for more than a year, yet if she should eat a teaspoonful of common beans, no matter how well cooked, it would, I am sure, precipitate one or more convulsions, in this case there seems to be a personal idiosyncrasy in regard to this vegetable, though a sudden fright as an external agent has induced a severe fit in the same child There are some epileptics who can not take milk in any form, some who do not like acids, but as a rule their appetites are fully up to the standard and their desires gauged only by their opportunity to crowd food down their throats Be it understood that I am speaking of epileptics who are more or less defective mentally

In dieting the epileptic, the first point to be considered is *regularity* Such patients, at home, if afflicted with so called good appetites, are allowed to feed at will, and I must say the ease with which they can swallow enormous amounts of food and pass it on through their intestinal tract without apparent suffering or injury is marvelous That an overloaded stomach will bring on a fit or fits is, I think, unquestionable, and the stomach to which additional supplies are being made at short intervals is in an even worse condition than the stomach simply overloaded, for when digestion ceases, fermentation and decomposition begin and the irritation increases proportionately We are dealing with patients who may never have known restraint upon their desires, for them we make a stringent rule—nothing to eat except at meal time

Another point is, eating properly It is said that Gladstone gave every mouthful thirty two bites before swallowing the bolus, and while this is all very well for those who will do it, it would be an impossibility to insist upon such a plan with our patients They may, however, by constant and careful attention, be trained to eat slowly, chew their food thoroughly and properly and use their knife and fork in a manner acceptable in polite society

Some have a very disagreeable habit of using their incisor teeth as molars, and much time is taken up in teaching them to roll the bolus of food from side to side and use the back teeth to disintegrate the mass and thus thoroughly mix it with the saliva before it is swallowed

It should not be difficult to understand the condition of a stomach into which the material of a meal has been introduced in lumps and almost solid masses, the mixture of an ordinary meal is bad enough, without giving the stomach the additional duty of chewing the food as well as digesting it, it is also an easy task to demonstrate the subsequent irritation of the above condition upon sensitive nerve masses, only needing a slight inducement to explode in a wild outbreak of nerve energy, as well as the future results upon the stomach itself and the general nutrition, and further argument for table decorum is unnecessary

Quantity is an important consideration when it is known that those who eat are not capable of measuring the limit of their desire for food by any reasonable standard Those whose temperament and ability permit them to take active exercise or engage in regular work which calls for an expenditure of muscular force, naturally need more food either in quantity or quality than those who are feeble, or those who by reason of their mental obliquity are disinclined to exert themselves The boys and girls who are approaching puberty, whose physiques are in that transition period between childhood and womanhood or manhood, need more proportionately than the older persons who have attained their full physical growth

Sir Henry Thompson[1] speaks of that period of youth "when the whole system abounds in vigor and strength, much superfluous food may be disposed of —first, by the greater activity of the functions of digestion and absorption, and secondly, by the capacity youth possesses for excessive muscular exercise, by which it can use up and eliminate such excess almost at will" While, however, the system of youth can overcome the effects of overplus, for a time, there must come a time when the relation between the "income" and the "output" must be maintained with care or the many and varied evils of overfeeding begin to show themselves

It will be found an easier task to keep the average man nearer the normal, under a regular and somewhat limited diet, than to maintain a close average of health upon an irregular and unlimited diet

The quality of the food bears a distinct relation to the value of the diet Not in the sense of the cost price, for that varies with the condition of the market and the amount purchased, while to the institution which raises its own supplies the cost is reduced to a minimum But food has certain values reckoned upon its chemistry It may be divided into—

1 Organic Nitrogenous (*a*) albuminates Non nitrogenous (*a*) fat, (*b*) carbohydrates

2 Inorganic Mineral (*a*) mineral,

It is a proper proportion of organic and inorganic, nitrogenous and mineral, albuminates, fats and carbohydrates supplied to the organism that enables metabolism or assimilation to take place, the term metabolism also refers to that power which the animal organism possesses of accumulating from its food supplies a store of potential energy, which it afterward transforms into kinetic energy or muscular work and heat, it also takes into consideration the excretory products resulting from the changes which have to be eliminated through the organs provided for that purpose

---

[1] Diet in Relation to Age and Activity

Equilibrium of metabolism means that the bodily income and expenditures are balanced, that while the normal physiologic conditions are maintained, there is exactly the same amount of new material absorbed and assimilated as there is of effete matter, the product of the retrogressive tissue changes removed by the organs of excretion, the destruction of tissue is exactly compensated by the formation of new tissue While the body is growing rapidly there is greatly increased formation in the parts participating in the rapid growth, and the metabolism in these parts is correspondingly increased, on the other hand, during senile decay the expenditure is in excess and the body in consequence wastes The physiologic equilibrium is practically determined by weighing and observing that the body remains of the normal weight with a given diet

In working out any problem with the defective class in question it is not easy to determine a standard, the variations in weight and height for the same age being only limited by the number of individuals weighed and measured, it is therefore hardly fair to draw more than tentative conclusions from data made up from comparison with normal individuals of the same age

Curiously enough, very few of the authorities pay much attention to the question of diet when writing of epilepsy Nearly all coincide with the opinion that meat is hurtful, and push this forward with some emphasis Hare, whose monograph upon the pathology and treatment of epilepsy is one of the most thorough and comprehensive upon that subject ever published, claims that very little has been done in the way of observing the effects of diet upon any large number of patients He mentions a report of twenty-four cases, twelve being placed upon a purely vegetable diet, twelve upon a purely nitrogenous diet, for a period of two months, with a result that the vegetarians had a few less spasms than the others, but the difference was so slight as to be of almost no weight in determining the question

I, myself, have been unable to put more than a limited number under observation, the six cases of my own were all chronic cases, in which the possibility of cure had been abandoned, and we only endeavored to reduce the number of spasms to the minimum and keep the general conditions of each as close to the normal as possible Each one was taking 60 grains of potass brom daily in four doses For six months meat was eliminated from their diet, a full regimen of vegetables, cereals and fruits, with brown, white and corn-bread without eggs being given, meat, eggs and milk were then added to the list for another period of six months, careful attention being given every month to the weight, and any variation below that of a preceding month being met by an additional portion of fat-making food Comparisons between the number of spasms for each month of one period and the corresponding month of the other, and the totals of the two periods, gave decidedly negative results, though the average of the six months of vegetable diet was slightly lower than that of the more general diet The variation in number of spasms was, however, only that which may be seen in any number of chronic cases under close observation

Further observation has led me to believe that in such old cases, *diet* has only a subordinate effect upon the fits, and it would seem that so long as care is taken to eliminate any article of food known to be indigestible and to prevent overfeeding, a good, generous and varied bill of fare is the best In cases where the general health is good, a diet very similar to that prescribed for athletes under training is advisable, for the growing child a fat and blood-forming dietary, and for the elderly and apathetic the most simple and easily digested articles Monthly comparisons of weights will show losses and gains, and thus permit any necessary change in the amount or nutritive value of the food

There seems to be much misunderstanding as to what a generous diet means The parents of our epileptics so many times protest that their child is kept upon the plainest possible diet, investigation showing the statement in some instances to be correct, but the patient is permitted to eat *all that he will*, under a very mistaken idea that because he wants it, his wants are actual needs, in other instances the so called plain diet is perhaps not a series of dishes fit to be set before a king, but really a rich and highly-spiced bill of fare, entirely unsuitable to a stomach which must not be overburdened, no matter what its capacity Other parents condemn a diet which, as they say, prohibits cake, candy, pastry and unripe fruit, or fruit known to be indigestible, and say that their poor child has so few pleasures in life, it is a pity to deny him such things, The taste for sugar is no doubt physiological and should be gratified but candy may be given judiciously just as well as a dessert, as to permit the child to eat it at any or all times So with fruit, though to my mind the swallowed pulp of oranges and half-chewed bits of banana have been responsible for many a convulsion, and such pleasures are surely a mistake if we are to obtain a cure

Unless combined with a certain amount of exercise, diet is of an uncertain value, that is the amount of food ingested to preserve the physiologic equilibrium of metabolism, must be modified Parkes says of exercise "A perfect state of health implies that every organ has its due share of exercise If this is deficient nutrition suffers, the organs lessen in size and eventually degenerate more or less" In common with his more fortunate brother imbecile, who is not afflicted with epilepsy, the epileptic defective is more or less imperfectly developed physically, narrow chests, drooping shoulders and ill-developed muscles so frequently complicated with paralytic deformities are very common

Very little can be done with the shriveled, useless, paralyzed extremities, though I have seen much improvement in some cases, where the muscles had not atrophied, from properly directed exercise, especially in the lower extremities from the use of a tricycle

Dr Graeme M Hammond, of New York, in a recent number of the *Journal of Mental and Nervous Diseases*, has a very interesting article upon the bicycle in treatment of nervous diseases, in which he cites thirteen cases particularly benefited by riding a wheel under direction In this connection, Hammond says of exercise "Exercise, when prescribed for nervous affections, should preferably be taken out of doors It must be combined with pleasure and should be prescribed not only with a view of strengthening the muscles, but also for its effect upon the mind The effect upon the mind is often of greater importance than the effect upon the body The feeding of the mind on self, and the continual mental introspection which is so common in neurasthenia, hysteria and hypochondria, should be combatted by prescribing an exercise which necessitates the pleasurable concentration of the mind on what is being done, something which demands a certain amount of skill for its successful accomplishment and which must therefore divert the thoughts from morbid channels, stimulate the mental faculties in a normal direction and engender a feeling of brain-rest and mental refreshment"

The value of exercise as pointed out by Dr Hammond in benefiting certain forms of nervous disease not complicated with spasms is equally marked in the treatment of epilepsy, though the method of exercising must be modified, or rather adapted, to a disease which manifests itself by throwing the victim out of his equilibrium All varieties of exercise where the patient's life or limbs will be endangered must be thrown out of discussion The daily risk of danger from falling is sufficiently great without adding anything more We want in these cases a series of exercises calculated to develop the entire muscular system symmetrically, correct any physical deformity as far as possible, and add nothing in the way of risk from a sudden fall In beginning systematic exercise with younger patients, the Swedish system of educational gymnastics is invaluable in educating the young, growing muscles for more complicated exercises giving the best possible results with the least exertion, stimulating not only muscular, but mental development as well, overcoming in a measure the muscle habit of involuntary contraction as seen in the epileptic fit, and generally promoting the physiological action of the internal organs

Epileptics suffer from obstinate constipation which is extremely difficult to overcome by ordinary treatment, and I am of the opinion that the acne of those who are taking the bromids constantly is in many cases as much due to irregular action of the bowels as to any direct effect upon the skin by the drug, this constipation, skin trouble and depression seen in some cases where larger doses of the bromids are being given may be cured in most cases by gymnastic and other active exercises, and there is rarely a case so stubborn that it is not at least benefited One of the most important effects of exercise is produced upon the lungs It is well known to those whose practice involves a close acquaintance with the chest capacity of the average man, that few utilize the entire compass of their lungs, *especially* is this seen in these defectives Now, if the observations of Valentin and Sczelkow are correct—that the greater part of the carbon dioxid which the respiratory organs throw off is formed in the *muscles*, exercises which shall strengthen respiratory effort and increase the lung capacity should be faithfully followed out Indirectly exercise may exert very valuable effects upon excitable nerve centers, as well as act positively in eliminating the waste products of the entire body

Motion, especially such as may be made toward some pleasurable end, and active work which brings with it some reward, will often break up a beginning epileptic mania, and I am satisfied that all epileptics should be kept as actively employed as their condition and environment will allow

Walking is as suitable an exercise as can be given No extra machinery is needed and the effect can be studied many times It must be compulsory and the distance increased as the muscles permit In these days of rapid transit the legs are becoming a secondary means of propulsion, whereas they should be the chief

Americans are celebrated the world over as a nation of dyspeptics It is certain that we are a nation who use every available means to get to our journey's end with the least possible physical exertion and in the shortest possible time, and the query arises whether the dyspeptic symptoms would not vanish with a revival of walking as a popular method of travel

Football is another method of overcoming the inertia of our patients by a pleasurable game, the striking bag of the pugilist may also be utilized for those who can stand the violent exercise, the modern wall-machines offer very elegant and very effectual means for developing the muscles But all such exercise, whether easy or violent, must be guarded by a watchful and intelligent teacher, lest more harm accrue than good

That diet and exercise are but subsidiary means in the treatment of epilepsy must be admitted, that they are valuable corollaries to such drugs as may be prescribed is, I think, equally true But unless properly prescribed and administered their therapeutic value diminishes

The time will come probably when a large majority of our epileptic population will be gathered together in branch asylums connected with our State institutions for the insane and feeble minded, or in private asylums devoted to that class of patients, and it is from these asylums, where the patients are under the eye and training of a medical officer who has himself been trained in physical culture and made a study of diet, that results are to be had worthy of study, until then we are, so to speak, in a realm of theory

The older and chronic cases are beyond cure and almost beyond amelioration, but there are many cases of young children among whom, if taken in time, removed from home environment and placed under discipline, carefully studied physically and mentally, thoroughly drilled in exercises calculated to increase muscular development and to develop muscular control, with less attention paid to teaching book knowledge and more attention paid to training in habits of obedience and decorum, I take it that more might be cured and certainly the care of the incurable would become a simple problem It may, I think, be reasonably concluded, that diet and exercise are important auxiliaries in the treatment of epilepsy, that diet should be, as the term implies, food prescribed by a physician, that an extreme opinion, either for or against a dietary consisting entirely of nitrogenous matter or, on the other hand, strictly vegetable, is entirely wrong, and a middle opinion, which will give the patient thorough study and afterward arrange the diet according to the patient's physical needs, is the proper theory, that exercise should also be prescribed by a physician and followed out under his eye as far as possible, particular attention being given to exercises calculated to develop respiratory action, strengthen the heart and generally promote muscular control

---

WHEN SHALL WE OPERATE IN CASES OF APPENDICITIS?

BY A M HAYDEN, M D
SURGEON TO ST MARY'S HOSPITAL, EVANSVILLE IND

The above question is one that every member of the profession is trying to solve The subject has been much discussed Learned essays have been written, read and discussed by learned bodies, often backed up by statistics which, according to the author's views, clearly establishes the correctness of the conclusions set forth in his paper He does not stop to consider the possibilities of inaccuracies of his statistics In fact, I am satisfied that our statistics of appendicitis and its results are not to be relied on

The disease and its classifications have not been sufficiently understood to make them trustworthy and a valuable aid to definite conclusions For instance a catarrhal relapsing form of appendicitis may apparently recover seven or eight times under medical or the expectant plan of treatment, and the ninth time, owing to the fact that the patient had had previous similar attacks and recovered without an operation, he refuses to be operated on until he is in a dying condition He then submits, and dies Statistics give eight recoveries without operation and one death with operation when in reality there are no recoveries, and all due to the fact that the one case had been treated by an advocate of the expectant plan of treatment, and had not been operated on Had the same individual been operated on during one of the earlier exacerbations of the disease he would have in all probability recovered, and statistics would show one case, one operation and one recovery, instead of eight cases recovered by medical treatment, and one case operated on and one death

Such statistics must necessarily be misleading In order to properly understand appendicitis, we should first classify the different varieties or forms of the disease, and so arrange the symptoms as to be able to make our diagnosis of the class of the disease we have to deal with by exclusion Until this is done, there will always be more or less confusion and difference of opinion in regard to treatment, whether it should be operative or medical First, then, we have an acute perforating appendicitis, which runs its course very rapidly, perforation taking place in from twenty-four to seventy hours, producing a septic peritonitis that proves fatal in possibly 95 per cent of all cases that are operated upon, and 99 per cent of all cases that are left to medical treatment Such cases, if correctly diagnosed and operated on before perforation, can nearly all be saved Then all cases belonging to this class should be referred to the surgeon for operation Second, we have a catarrhal appendicitis, which is an inflammation due to bacillus coli communis traumatism or a foreign body in the appendix, such as fecal concretions or seeds, the latter cause is seldom present This form is usually of a recurring or relapsing nature, one or more attacks occurring within a shorter or longer period Some cases are accompanied with suppuration and abscess within or without the peritoneal cavity Some cases result in perforation and cause death very much in the same manner as those cases of acute perforating appendicitis This form of appendicitis is the one that has caused so much confusion and difference of opinion in the profession in regard to what treatment should be adopted Some of the cases terminate by resolution and the patient gets well without an operation, some terminate by suppuration, point externally, open and the patient recovers Those cases that terminate in perforation, producing peritonitis, are the ones that the surgeon is often called to operate upon, and generally after fatal septic peritonitis has taken place.

He operates to give the patient the benefit of the little chance left, death follows, the physician says, "I told you so," and writes a paper condemning operative procedure in cases of appendicitis to be read before his medical society He has probably treated a few cases of recurring catarrhal appendicitis and succeeding in relieving them of their attacks, for the time being, left them for some surgeon to operate on in the future, he is then able to draw statistics He has three or four recoveries from medical treatment to report, and one case where surgical treatment failed He does not state what the result would have been in the case treated surgically had it been treated medicinally In my judgment, the only way to arrive at a trustworthy decision of the comparative value of operative or non-operative treatment of appendicitis would be, not to report a case as cured when treated medicinally until a sufficient time had elapsed to be sure the case was well and would not return, say a period of two or three years We should also include the cases under this head that had been so treated until they were in a dying condition before operative interference In other words, all cases operated on after medical treatment of a longer or shorter time, and at the time of operation were found by the surgeon to be in a condition that excluded the possibility of recovery, whether operated upon or not It is unfair to surgery to class such cases as surgically treated, and statistics based on such classification are of no value On the other hand, in making up statistics for the surgeon the only cases that should be included are those that have been treated by the surgeon from their incipiency, cases where the surgeon had been privileged to operate at the time, in hi judgment, was the most suitable or most promising Such statistics when carefully compiled would be valuable aid to the physicians as well as the surgeon in determining the course of treatment to be pursued What is needed at the present time is more thoroug knowledge of the different phases of the disease an the peculiar symptoms accompanying each, that w may be able to distinguish one from the other an so determine the best method of treatment Unti this is accomplished there will always be the wides difference of opinion in regard to what treatmen should be adopted It would also be well for th physician and surgeon, while investigating the differ ent phases of the disease, to carefully study the earl symptoms that he may be able to recognize the ex istence of the disease in its incipiency, as a favorabl result often depends upon early treatment, especiall so when surgical means are resorted to Among th earlier symptoms are more or less pain over the a domen, tenderness over McBurney's point, midwa between the umbilicus and crest of ilium, sometime cramps in the bowels, with diarrhea or nausea either of the above symptoms are present we should suspicion appendicitis and make a careful examination for the same If we recognize it at this stage and operate, 95 per cent of our cases will recover If we fail to make our diagnosis until we have a general septic peritonitis, then we have a complication that will add very greatly to the mortality under any treatment After peritonitis takes place we nearly, if not quite, always have perforation, and, excluding cases of peritonitis caused by septic tubes or ovaries, perforation of bowels by ulcers or traumatism, peritonitis means appendicitis During the last five or six months I have had several cases, two especially interesting, which I will report

March 6, I was called six miles into the country to see a young man about 30 years of age Upon arrival I found he had been awakened during the night with severe cramps in his bowels, attended with diarrhea and some vomiting, his temperature was normal pulse 80 per minute, respiration 18 Upon physical examination I found the skin moist and cool, tenderness over the entire belly but no distension or tympanites, tenderness over McBurney's point was more marked than anywhere else, and on deep palpation I imagined I could detect a small indurated mass I diagnosed appendicitis and advised an immediate operation Upon inquiry on the part of the patient if it were not possible for him to get well without an operation, I told him that very few cases recovered without an operation, but that when they did the trouble often returned and continued to give trouble, and sometimes perforation took place, producing peritonitis, which nearly always proved fatal He finally said he would think it over until the next day when he would give me an answer The next day I found him comfortable, no fever, no tympanites less tenderness over the abdomen and very little over McBurney's point I imagined that the induration I had felt the day before had disappeared The patient was not ready to be operated upon and I was much less inclined to urge it I continued to see him every other day for about ten days, during which time he continued to improve, with regular bowels, no pains, or very little if any I discontinued my calls with instructions to call me at once if any untoward symptoms should manifest themselves Two days later I was sent for in a hurry to see him I found his temperature 103, pulse 100, and quite an indurated mass in right iliac region I now insisted on an immediate operation He was sent to St Mary's Hospital and I operated on him the next day, March 21 I found necrosis of the appendix, and also quite a large portion of the bowel The appendix had sloughed off and was found in the cavity with the pus and fecal matter that had escaped from the bowels I removed the appendix, closed up the opening in the gut, washed out the cavity and packed with iodoform gauze The patient recovered, but he was two months at it He had no fever or peritonitis after operation The wound suppurated, the necrosed gut separated, came away and left a large fecal fistula through which all his stools passed for a month The fistula finally closed and the patient is now well Had he submitted to an operation when I first saw him it would have been much less dangerous, and he would have been well within two or three weeks with one-tenth of the suffering and annoyance that he had as it was The other case occurred in a young man 31 years old I saw him on Sunday morning at 6 o'clock, Nov 3, 1895, and found his temperature 102 5, pulse 90, tenderness over the abdomen, and quite an indurated mass in right iliac region, which was extremely tender on palpation He stated that he had first felt pain and uneasiness in the bowels Thursday night, he was better Friday, and went to the office to look after his business, Friday night he again felt bad and had considerable pain in bowels, Saturday he was again feeling better, and went thirty miles in the country to attend to some business on his father's farm, his bowels moved as usual Friday and Saturday, without pain, Saturday night he had a severe pain in the bowels, attended with fever and a swelling in the region of the vermiform appendix He then realized he had an appendicitis (he being a physician), he also knew something must be done to avert the impending danger, and he sent for me at daylight to operate I examined the case, diagnosed appendicitis I laid the facts before him as I saw them, and advised an immediate operation, which he consented to at once He was taken to St Mary's Hospital, where I operated on him at 11 o clock I found perforation of the appendix, with quite a quantity of fecal matter and pus, which was shut off from the peritoneal cavity by the flimsiest kind of adhesions The wall formed by the adhesions was so frail that I am satisfied they would have given away before a few more hours' accumulation of pus and allowed the contents of the cavity to escape into the general peritoneal cavity which would have precipitated an attack of septic peritonitis that would, in all probability, have proved fatal The patient's convalescence was uninterrupted

I might go on and report a great many more cases in evidence of the importance of early operations, but I think the above are sufficient Nearly all operators with much experience have reported many cases where early operations were the means of saving lives, while had they been delayed death must certainly have followed In conclusion, I think until we are able to differentiate between the cases that are going to perforate and allow the contents of the bowels to escape into the peritoneal cavity and those where nature will throw out plastic lymph and form a wall separating the diseased appendix from the peritoneal cavity in such a manner as to seal up the pus cavity and thus cause it to open externally, and the catarrhal relapsing variety, which sometimes recovers without operation, by means that are unmistakable, that all cases of appendicitis should be operated upon as soon as diagnosed, because the danger is almost *nil* before perforation, but after perforation an operation will not always stop the progress of the septic condition Of course some cases will never recur, and if we operate on all cases we would operate on some that would get well without an operation, but with our present knowledge we can not tell which case will recur and have no relapse and which will not, and by waiting until rupture has occurred many cases will die which, by prompt surgical interference, would be saved

The Health of the Pope —His Holiness is so far reëstablished in health that on several of the bright, dry, exhilerating days we have been enjoying lately he has been able to take carriage exercise in the Vatican gardens These outings are timed for midday, when the warmth is greatest, and have included a visit to the Tower of Leo IV and to that stretch of the gardens which is cultivated under His Holiness direction —*London Lancet*

ON SOME DIFFICULTIES IN REFERENCE TO THE EARLY SURGICAL TREATMENT OF APPENDICITIS

BY CARL BECK, M D

PROFESSOR OF SURGERY AT THE NEW YORK SCHOOL OF CLINICAL MEDICINE, VISITING SURGEON TO THE ST MARK'S HOSPITAL THE GERMAN POLIKLINIK, THE GERMAN DISPENSARY OF THE WESTSIDE OF NEW YORK CITY ETC

Although discussions upon appendicitis have been quite numerous lately, I hope there is no need to apologize for bringing this subject up again In view of the immense importance and the great interest which attach to this disease, and also of the *many points still entirely obscure and unsettled* in connection with it, and last, but not least, the continued existence of so many skeptics as to the prevalence of the affection as well as to the importance of its surgical treatment, it can not at present be discussed too frequently

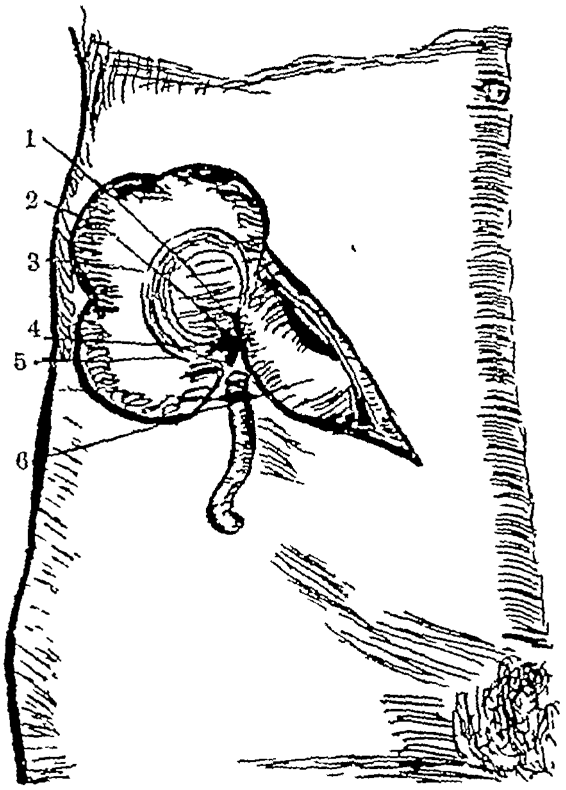
While it is true, that the surgical technique of the operation for appendicitis has reached, especially through the efforts of surgeons of this country, a state of perfection hardly to be excelled, it is to be regretted on the other hand that, as to the affection itself, particularly as to its etiology, diagnosis and prognosis, a vast number of errors still prevail This deplorable fact appears to me to be the more important in that recently even the general press has taken a great and most unpleasant interest in this particular *locus minoris resistentiæ* of our medical knowledge Thus an obstruction policy is raised against timely surgical interference, which doubtless handicaps the treatment of a great many cases

As stated before, the technical part of the question before us has reached a state of most gratifying perfection As soon as the abdominal cavity is opened, the further surgical strategy is, as a rule, clearly outlined

If the operation is done for relapsing appendicitis, if, in other words, a simple appendicectomy is to be performed, no difficulty is encountered Under the auspices of thorough asepsis, in fact, the prognosis is most excellent The incision, at least four inches in length, should be made parallel with Poupart's ligament and with its center opposite the spina anterior superior ossis ilei In th way enough space is secured to allow complete and safe work The section of the musculus obliquus externus and of the aponeurosis should be made to correspond, care being taken by using blunt instruments (handle of scalpel, of closed Cooper's scissors) not to cut any fibers crosswise If the parts, thus separated, are well readjusted after the operation, perfect union will take place Thus formation of abdominal hernia will best be prevented Care should naturally be taken to use the same blunt instruments for separating the fibers of the musculus obliquus internus and transversus, the direction of which is somewhat oblique to those of the musculus obliquus externus

After the peritoneum is divided and the caput coli pulled out, the appendix is easily brought to view and removed Care should always be taken to ligate the mesenteriolum of the appendix in several portions, before the latter is severed Having carried out this precaution a reliable assistant presses the appendicular region of the cecum firmly together in order to prevent any outflowing of the intestinal contents, while with the scissors the appendix is snipped off very close to the cecum Previous to the separation, however, if palpation has shown the presence of fecal matter within the appendix itself, it is my custom to prevent its escape by surrounding the appendix with a ligature close down to the point of the intended division (See illustration) In case of insufficient assistance it is advisable to put a prophylactic suture around the base of the appendix *between the point* of the intended division and the cecum This can be removed after the small opening is closed The closing is effected by two to three Lembert's sutures of thinnest silk, inserted through the serosa Perfect approximation is facilitated by stripping the musculo-serous coat somewhat backward to the cecum, just as the skin flap is retracted in a circular amputation, and cutting off the protruding mucous coat

A small amount of iodoform powder is dusted into the inner surface of the stump, but the wound itself must not be brought into contact with any antiseptic substance Silk is chosen for the peritoneal work, as well as for that of the abdominal wall, on account of its antiseptic reliability, which, in my mind, outweighs the otherwise considerable advantage of catgut



APPENDICECTOMY

1, 2, Prophylactic ligature 3, Cecum 4, Stump 5, Protruding mucosa ligature 6, Lower portion of ileum

The same principles hold good when extensive adhesions are found These are divided To gain more ground for safe work it will be sometimes advisable to add a second incision, rectangular to the first and running from its center toward the spina anterior superior ossis ilei It is to be understood that union by first intention is striven at just as in a case of ordinary appendicectomy

But an entirely *different plan of treatment must* be pursued if the inflammatory process has been followed by the formation of an abscess Most fortunately, protecting adhesions are established in the great majority of such cases, creating a real empyema (I would propose to call this pyo appendix, in analogy to pyothorax, pyosalpinx, etc) As this is practically an extraperitoneal abscess, it gives a most excellent prognosis, as a rule, and is not to be compared in significance with that of a pus accumulation in the free peritoneal cavity.

The incision through the abdominal wall in such cases should be the same as described above. Then, after the peritoneum is reached, a grooved director is introduced in the direction of the abscess. As soon as pus appears in the groove of the instrument, a small Pean forceps is pushed in alongside the groove of the director. After the opening is gradually dilated, the cavity is exposed by holding back the tissues with blunt retractors. If the appendix is now found lying free in the cavity, its removal is a matter of course. The whole cavity is then packed loosely with iodoform gauze, which is then protected by a large layer of mossboard.

When, however, the appendix is gangrenous and is surrounded by strong adhesions, having become, in fact, a portion of the walls of the pus cavity, thereby shutting off the latter from the great peritoneal sac, the danger of its immediate removal would be very great. It is a well adopted surgical principle to remove gangrenous tissue, wherever it may be, without delay. But like many other axioms this has to be taken *cum grano salis*. The punctum saliens will be here, whether the price paid for the removal of such an appendix is not too high. While it would certainly be desirable to see such a dangerous element eliminated, the breaking-up of the protecting walls would certainly entail the greatest possible risk of infecting the whole peritoneal cavity. Great is the difficulty of determining a border line between radical and conservative indications in such cases, and it will frequently be left solely to the surgical instinct whether the appendix should be hunted for and removed or not. The more radically disposed surgeon, eager to avoid possible recurrence, tries to get hold of the appendix, cost what it may. The conservative surgeon, eager to avoid infection of the general cavity by risky manipulations, is apt to satisfy himself too easily by simple evacuation of the liquid contents of the cavity, thereby assuming the risk of overlooking a second pus accumulation. It is deplorable that, so far, it has been found impossible to lay down a golden rule for the guidance of the surgeon at this herculean crossway.

If the gangrenous appendix is not removed, it should be carefully surrounded by iodoform gauze, in the expectation that it can be removed a few days later. Beside packing the cavity with iodoform gauze it is advisable to pour in about a tablespoonful of a 10 per cent. mixture of iodoform-glycerin.

If appendicitis has ceased to be a local infection and a general peritonitis is fully established, the surgeon is at a loss in the far greater majority of cases. Much, however, can sometimes be done by careful and extensive examination of the peritoneal cavity, the finger or grooved director being valuable diagnostic means. Such explorations, done if possible under anesthesia, frequently disclose conditions, which by superficial examination were not discovered, such as secondary abscesses between the loops of the intestine, etc. Here the treatment should be to thoroughly evacuate the abscess, wash out the peritoneal cavity with a hot saline solution, carefully wipe off the fibrinous exudations, and introduce iodoform gauze—preferably wicks, on account of their greater absorbent power—or small drainage tubes surrounded by iodoform gauze, as advised by Mikulicz. Such procedures will once in a while, even in bad cases, meet with astonishing success. Clinical experience has shown that recovery has taken place even when the surgeon proceeded to the operation without a spark of hope, where, for instance, the pulse was not perceptible. Vice versa, however, cases have ended fatally where the prospects were comparatively good. It is no doubt depressing for a surgeon to proceed to heroic manipulations under such circumstances. But it should not be lost sight of, that a patient suffering from general purulent peritonitis has, indeed, nothing to lose. He should therefore be operated upon at all hazard. The permission of the patient can be obtained almost always on account of his great suffering and his cognizance of the unfavorable outcome of treatment by internal medication. It has been my experience that the trouble in getting the permission in such cases comes from the attending physician and not from the patient or his friends. Consultation and consideration usually consume most valuable time.

ABDOMINAL SCAR TWO WEEKS AFTER APPENDICECTOMY

Extensive exposure of the peritoneal cavity enables the surgeon to evacuate the pus from pockets and crevices of the abdominal cavity and destroy adhesions which form the walls of small abscesses. These adhesions are generally the outcome of a previous inflammatory process, and often form a great impediment to the thorough evacuation of the pus. A thorough disinfection of the abdominal cavity is still a desideratum, but if at least a large quantity of infectious material is removed the degree of the toxic influence is considerably reduced. By thorough evacuation also the intra-abdominal pressure is necessarily lessened, so that the respiration, as a rule, becomes much freer

How much such heroic procedures as alluded to above can sometimes achieve, may be illustrated by a case of my own, the history of which I beg to submit (Compare Beck, "Tubercular and Suppurative Peritonitis," *New York Medical Journal*, April 21, 1894)

Jacob W , aged 7 years, who had always been in good health before, was suddenly taken sick with chills and sharp pains in the region of the umbilicus Vomiting set in a few hours later Dr Sandberg of this city, who was called in, administered laxatives and also washed out the stomach and bowels without effect, he was accordingly led to suspect ileus from intestinal obstruction and advised immediate laparotomy When I saw the patient on the evening of May 17, 1893, I found a strong, well-nourished boy, showing the typical facies Hippocratica The weak pulse was 131, temperature 101, and the respiration 32 The abdomen was tympanitic and very painful to the touch Resistance or particular tenderness at the right iliac fossa was not present After thorough aseptic preparations at the house of the patient, an incision, 5 inches in length, was made in the manner described above About three tablespoonfuls of gray malodorous pus were discharged The intestines were found glued together by fibrinous adhesions to the extent of about half of the peritoneal cavity They were of a dark red color and could be brought to view only after a cross incision, rectangular to the original one, reaching nearly as far as the umbilicus, was added Above the synchondrosis sacroiliaca dextra a second pus cavity was found and evacuated By hunting for the appendix the cecum was found tightly adherent to the synchondrosis sacroiliaca dextra, from which I was afraid to separate it It can safely be said, that fully two yards of the small intestine, covered with fibrin and purulent exudation, were carefully pulled out, washed with sterile water, and wiped with peroxide of hydrogen Iodoform powder was dusted over all the portions of the intestine, which had been covered with exudations The edges of the cross incision only were united One loop, about twelve inches in length, was kept outside the abdominal cavity, as it had a dark blue tint, which gave a suspicion of possible ensuing gangrene It was enveloped in iodoform gauze and the fossa iliaca dextra was also packed well with the same material and the whole was protected by a large moss-dressing

After the patient had rallied from the shock, his condition became quite satisfactory, until, five days later, pain as well as a considerable elevation of temperature induced me to examine the cavity closely by introducing my index finger, whereupon a retention of pus was discovered in the lumbar region A counter incision was made at once above the crista ossis ilei and a large drainage tube, surrounded by iodoform gauze, introduced Great improvement followed this procedure It was not ten days before I replaced the enveloped portion of the intestine At the same time I again tried to find the appendix but in vain, and as the patient made rapid and satisfactory improvement, no further attempts were made to improve it

Three weeks after the first operation the patient was seized with sharp pains in the region of the bladder, frequent micturition troubled him and his general condition became considerably impaired No retention of pus could be detected, nor did examination through the rectum and the urine reveal anything in particular The patient gradually became weaker, had incontinence of feces and several attacks of syncope After I had conquered a good deal of opposition, the patient submitted to another operation By pushing the index finger toward the bladder, adhesions were destroyed which had formed the walls of a cavity, extending from the posterior wall of the bladder to the rectum Two tablespoonfuls of creamy pus were discharged Forcing my index finger as far as possible toward the opposite side, I succeeded in incising on its tip, so that a drainage tube, nearly one foot in length could be pulled through Great improvement followed this time also, and two weeks after a portion of the drainage tube was pulled out This "post-vesical cavity" was now drained from the right side only, so that the counter-opening on the left side became obliterated Contrary to my instructions the patient was allowed to get up and was taken sick again with chills and convulsions, the source of the trouble this time again being furnished by retention of pus in the same post-vesical cavity Drainage was again established as before, from the right to the left side When the symptoms had subsided, the drainage tube was pulled out from the left side and the old right opening was allowed to obliterate Two weeks later the drain was removed entirely and iodoform wicks substituted for another week, after which recovery became perfect In the right iliac region a large ventral hernia is left, doubtless due to the weakening of the abdominal wall by the long continued drainage As it does not disturb the patient, it is difficult to persuade him to submit to a secondary operation

In this case the dangers arising from repeated pus retention were readily counteracted by energetic interference So fortunate an outcome, however, must be regarded as an exception Though we are well-nigh letter-perfect in the technique of operative treatment of appendicitis, we are deplorably ignorant of its etiology If we accept Chauffard's dictum "*Toute la thérapeutique est dans l'étiologie*," such ignorance may furnish the explanation of the uncertain therapeutic measures which are still adopted by many physicians at the early stage of the disease

It is customary to say that the prognosis of the disease depends upon its toxic agent, but this is a rather defective explanation Appendicitis may have its starting point in a simple inflammation of the mucous membrane of the cecum near the ilio-ceca valve Such catarrhal process might easily extend into the appendix, and even though giving rise to no immediate symptoms might, nevertheless, produce a stricture of its lumen that would lead to retention, or it may even obliterate a part of the appendix (appendicitis obliterans) Even during such slight inflammation the patient is always exposed to the danger o peritonitis, be it caused by perforation or not The protecting epithelium of the mucous membrane o the appendix might also become displaced or eroded so that bacteria can easily invade the rich layer o adenoid tissue beneath, finding there most favorabl conditions for their development As the bacillu coli communis has its permanent domicile in thi part of the bowels, and as it very frequently is found in pus cavities in or around the appendix, it was a first thought to be responsible for the trouble Bu other microorganisms are also found in compan with the bacillus coli communis, particularly th streptococcus Welch advanced the theory, that is the companionship of these two microbes whic excites inflammation in this connection, and tha the fact that the streptococci were not found shoul not be considered a sufficient proof of their absenc The colonies of the bacillus coli communis grow s much more rapidly and extensively than those of th streptococcus, that the much smaller ones of the la ter may be completely overshadowed But as bot microbes exist in the intestines of every individua certain conditions, still unknown to us, must arise i order to give these elements a chance to exert the infectious influence Do such conditions exist i changes of the mucous membrane as alluded above or in circulatory disturbances caused by th curved and angular shapes of the appendix, by a insufficient supply of blood or by encysted fecal ma ter, particularly if previous catarrhal inflammatio has left a stricture? Regarding foreign bodies as a etiologic factor, I must say that in about one hundr and fifty cases of appendicitis operated upon in m own practice, I have been able only once to discov one seed For the last few years I have taken particul pains to search for the appendix in all my other cas of laparotomy, and have repeatedly found ha masses, probably fecal matter, in the lumen appendicis in individuals who had never up to that time and have never since shown any symptoms of appendicitis Slight pressure sufficed to press such contents out into the cecum I have frequently asked myself in such cases, whether it were not my surgical duty to remove the appendix, but up to date I have not been able to convince myself of the necessity of such a radical step Such observations, however, have led me to believe, that despite the absence of a circular muscular layer, circulation of fecal matter in the appendix is possible

In considering the microbiotic theory of the causation of appendicitis we must also not overlook the fact that the micrococcus lanceolatus (Fraenkel), the bacillus pyogenes fetidus and other microorganisms are also found in the pus formations Furthermore, in reference to the much-discussed bacillus coli communis, it must also be borne in mind, that according to the experiments of Kiessling (Hygienische Rundschau Bd 3, p 724), what is usually called bacillus coli communis does not represent a a single bacterial species, but that a great many intestinal bacteria are grouped under this head, which, though alike in several respects, differ distinctly in others Apropos of the whole germ theory of disease, it will doubtless puzzle us for a long time to name the conditions under which the same streptococcus will set up a trifling tonsillitis in one case or a fatal meningitis or appendicitis in another Nor will it be less difficult to explain why the same toxic elements in one case cause a circumscribed inflammatory process or a localized abscess, while in another they produce rapidly fatal septic infection Undoubtedly there exist various forms of sepsis, which our defective means of diagnosis hinder us from differentiation If we were cognizant of these conditions it might be possible to form a prognosis by bacteriologic test During operation, of course, specimens can easily be obtained Unfortunately, however, only a few microbes can be recognized by the microscope alone, so that no adequate conception either of the cause or of the amount of the sepsis can be formed The great majority of microbes at present known can be made out only by bacteriologic examination, which has the disadvantage that the cultivation of most species consume so long a time as to be practically useless in this connection Therefore, clinical experience, ocular inspection and the estimate of the general condition will more often furnish the grounds for prognosis as well as the indications for further surgical steps

Difficult though it may be in many cases to determine the best course to pursue after we have opened the abdomen—how much more difficult is the decision before it has been done Are the symptoms, so well known to us through the text-books, always sufficiently developed at an early stage, the stage which warrants success after surgical interference? The diagnosis of appendicitis is based upon the presence of acute abdominal pain, the suddenness of the attack, the tenderness and resistance at McBurney's point, the occurrence of nausea or vomiting together with more or less febrile disturbances Increased temperature in itself is not a reliable symptom, but Madelung regards a marked difference in temperature between that of the mouth and that of the rectum in favor of the latter as peculiar to this disease

But all the symptoms mentioned are at times also found in other abdominal diseases The surgeon's knife has frequently demonstrated the presence of appendicitis in cases in which a diagnosis has been made of psoas abscess of the abdominal wall, typhlitis, perityphlitis, paratyphlitis, salpingitis, oophoritis, peritonitis, intestinal obstruction, typhoid fever, cholelithiasis, hepatic abscess, nephrolithiasis, and even of malaria, influenza or pneumonia Very often the patient has reached the autopsy table before the error diagnosed has been discovered The effect of these unfortunate mistakes has been to bring cases to the surgeon's notice at an earlier stage than formerly, and to throw upon him the responsibility of choosing between the danger of delay and the rashness of operating before the symptoms are sufficiently developed Is it fair to expect that he will always choose aright? As explained above, he can not at that stage of the disease obtain sufficient knowledge of the toxic agent and of its significance and localization Is it possible, for instance, to recognize a small ulceration in the appendix or to distinguish it from a so called benign catarrhal process? There is, as a rule, not a single reliable symptom for differentiation As soon as perforation has taken place the symptoms become violent enough to leave no doubt—but then the disease is no longer appendicitis but peritonitis

It has always seemed to me, however, that the thing to be feared in cases of appendicitis is not as much the danger of perforation as the possibility of septic infection from the original seat of inflammation If this be so, early operation would seem to offer the strongest, frequently the only chance of success This would imply that the surgeon should operate even during the first twelve or twenty four hours A family physician holding this view might be disposed to urge immediate operation But woe to the surgeon, if his expectations are not realized after the abdomen is opened It has happened, that just he who urged most strongly, will be his most pitiless critic, shifting all responsibility upon his shoulders If, on the other hand, the surgeon defers the operation until the symptoms become more manifest, any unfavorable result will subject him to the same ungrateful treatment I have a vivid recollection of a 6-year-old boy who, after having swallowed a considerable number of orange seeds, was suddenly seized with sharp pains in the right iliac fossa Vomiting and slight convulsions set in shortly afterward His temperature was 106 F, pulse 144 and respiration 42 Tenderness at McBurney's point being also discovered the family physician, quite naturally, made a diagnosis of appendicitis The fact that the boy's abdomen had been jumped upon by a companion during play seemed to add further weight to this opinion A well-known surgeon of this city was called in on the same day, but as he could not ascertain any marked resistance in the right iliac fossa, advised expectant treatment The right leg of the patient, by the way, could be lifted without causing any pain I had a chance to see the patient at the same time A general examination of the patient gave me the impression of a pulmonary disturbance, the difference in the percussion note, however, being only slight It was agreed to call in a specialist for lung diseases, who, upon examining the child on the following day, made the diagnoiss of pleuro pneumonia [Three weeks later I resected a rib for pyothorax, recovery]

This case is simply a sample of many of the cases in which a surgeon is called to operate for appendicitis where no appendicitis exists. They all serve to show that physicians have learned that procrastination in the surgical treatment of appendicitis is a dangerous thing. And yet, while in the case described above, a laparotomy, although in this connection an unfortunate procedure, would perhaps have been justifiable, in other cases a thorough general examination would have been sufficient to show the inadvisability of operation. It seems to be the opinion of some physicians that, if any trouble arises in the region of the right iliac fossa, no further testimony as to the existence of appendicitis is required. For instance, I was recently called by a most able brother to see a young woman who, six weeks after confinement, was supposed to have acquired appendicitis. There was acute pain in the right iliac fossa, distinct tenderness, vomiting, constipation and slight fever. If I had suggested an operation the family physician as well as the family would have consented at once. Examination of the sexual organs had previously been proposed by the physician, but the patient had stubbornly refused it. Having finally overcome these objections, however, we easily made out a salpingitis, undoubtedly due to the confinement.

In this connection let me say, that in operations for salpingitis I have repeatedly found the appendix participating in the inflammatory process, its end being sometimes soldered to the ovary. I have several times removed ovary, salpinx and appendix together, imbedded in a colloid mass. In such cases, which naturally were preceded by inflammation of long standing, particularly after confinement, the peritoneum was partially resected, as it was found considerably thickened. All these cases turned out well.

Considering all the points alluded to above, it is doubtful whether the time will ever come when it will be possible to make a rational prognosis of the course of appendicitis through its early symptoms, particularly as to whether the case will be one that will "heal spontaneously." This much, however, should be maintained, that appendicitis should not be looked upon as a medical disease up to the time that it has reached an "operative stage." It should not be left to the family physician to call in the surgeon when he wishes him to operate, thus putting the surgeon in a most undesirable position in relation to the case. It should not be left to the family physician to decide whether the operation is to take place at all or when, but the surgeon should bear the full responsibility from the very beginning. An illustration of the fairness of such demand may be furnished by the following case.

A man, 37 years old, a builder of this city, while on a vacation in the Alleghany mountains, had an attack of appendicitis, which was recognized as such by his physicians at an early date. Medical treatment was advised. As the patient himself was aware of the dangers of his disease and also of the advisability of early operation, he demanded a surgical consultation. His condition having improved two days after the onset of the disease, a report was sent to me by the physician, saying that the necessity for an operation had fortunately ceased, but if against all expectations my surgical assistance should be wanted a telegram would be sent me. On the following morning they summoned me to operate. After having gone more than one hundred miles of my journey, I received a dispatch on the train telling me not to come, as operation was unnecessary. Thinking that the patient had succumbed to the delay, I returned. Two days later, to my great surprise, the patient appeared in my office, telling me that on account of his great improvement two days before, after he had had another severe attack, the physicians had persuaded him to keep surgical interference at a distance. This morning, although he had had another attack of violent pain and was feeling very weak and nauseated, he had made up his mind to risk leaving for New York, a journey of ten miles on mountainous roads and six hours' travel on the train. In examining him I found all the classical signs of appendicular abscess, particularly the pain and the presence of a tumor in the right iliac fossa. His temperature was normal, pulse 76 and respiration 29. He could only walk in a bent position. At the operation, which was performed on the following day, a gangrenous appendix was found, loosely attached to the hard walls of a cavity which contained a pint of yellow creamy pus. The wall of this cavity completely excluded it from the cavum peritonei. The opening left in the cecum after the removal of the appendix could be closed only with great difficulty. Two days after operation feces were found in the cavity, indicating the presence of a fecal fistula which, however, became obliterated two weeks later. With this exception recovery was uninterrupted.

In this case the diagnosis was made at the proper time and therefore immediate operation was indicated. The physician who advised procrastination may feel excused by the fact, stated by so many capable men, that a number of cases of appendicitis recover without operation and that the appendix was repeatedly found healthy when an operation for supposed appendicitis is performed. In reference to the first point, however, there is a doubt whether the diagnosis is covered in those cases of appendicitis which are said to heal spontaneously, and, furthermore, whether such recoveries are not temporary and whether the fortunate outcome at a time has not to be dearly paid for by a sudden perforation or spreading infection in a second attack.

In reference to erroneous surgical diagnoses it may safely be maintained that they can fairly compare with those made by the pillars of general medicine. The few surgical mistakes made in this connection are well offset by the numerous fatal cases of appendicitis, not recognized and consequently not operated upon, which, if they had been given the advantage of an early exploratory incision would probably have recovered.

Weighing all the numerous difficulties alluded to, I may summarize my conclusions in that, if there is any doubt as to the presence of appendicitis at an early stage, an unnecessary exploratory incision is by far the lesser evil.

Another Fatality Chargeable to Athletic Sports.—A press dispatch from Salem, Mass., states that a young man, aged 25 years, died Dec. 6 from the effects of being struck on the head by a polo ball at the Salem and Fall River game. He did not complain of the injury until after reaching home. Medical assistance was procured, but it was of no avail. Serious injuries to polo players are not infrequent by reason of falls and collisions, but fatal accidents are not so common as might be expected. We do not remember heretofore to have seen a reported death chargeable to a blow from a polo ball.

Chicago Pathological Society

Regular Meeting, Nov 11, 1895

Weller Van Hook M D, President, in the chair

D W Graham, M D, made a report of cases with specimens

Case 1—Hypertrophied Bladder, Kidney and Ureter—Mr A F, 27 years old, entered the hospital Sept 17 last with extensive extravasation of urine invading the peritoneum, scrotum and penis and extending up over the pubes This began four days before with spontaneous rupture of the urethra from strictures There was already when the patient entered, profound septicemia, from which he died on the 19th, notwithstanding free incisions with drainage and external urethrotomy The patient had a history of gonorrheal stricture of two years duration with little or no treatment for the gonorrhea and no treatment for the stricture A limited post mortem examination was obtained The right kidney and its ureter seemed normal in size and consistency The left kidney is twice its normal size but there is no hydronephrosis The ureter is dense and as thick as the little finger The bladder walls are enormously thickened, averaging three fourths of an inch, and the cavity can not be made to expand to more than one-fourth or one third its normal capacity The microscopical sections show the hypertrophied bladder wall to consist of muscular tissue

The specimen is interesting as showing some of the remote results of gonorrheal urethritis when not treated, as well as the immediate consequences of untreated urethral stricture

But it is particularly instructive as explaining what is generally called and treated as chronic cystitis or irritable bladder following stricture even when all the obstructive symptoms of stricture as such have disappeared A patient with a contracted bladder cavity like this and hypertrophied bladder wall would necessarily have frequent micturition both night and day in spite of any and all kinds of drug or instrumental treatment

Case 2—Microscopic Specimen of Anatomic Tubercle—It was excised from the middle knuckle of the hand of a medical student recently It began while working in the dissecting room last winter The section shows characteristic tubercular tissue but tubercle bacilli have not been demonstrated Anatomic tubercle is now universally recognized as a local tubercular infection of the skin and occurs in the form of a warty elevation, a softened thickening at intervals, or as a thickened erythematous patch This specimen was of the latter form When favorably situated they should be excised

Case 3—Chronic Bursitis Popliteal Bursa Extending into the Leg—The patient was a male 20 years old large, robust and muscular He was apparently free from all the constitutional diseases, such as tuberculosis, rheumatism and syphilis to which chronic bursitis is generally ascribed There was only a slight suspicion of hereditary syphilis He had been under my observation somewhat irregularly for two years complaining of pain and soreness on the inner side of the right leg and a limited disability in walking During this period the patient was on antisyphilitic treatment part of the time because the pain seemed to be in the bone and periosteum and of possible hereditary origin After an absence of several months he reported to me in May, last, with an oval fluctuating swelling situated midway between the knee and ankle, and between the inner border of the tibia and the muscles Aspiration showed the sac to contain a synovial like fluid Later I extirpated the sac which I now exhibit, and which when removed, was as large as a goose egg The intimate connection of the sac with the deep fascia and the periosteum seemed at first to point to some kind of a congenital cyst It developed, however, that the upper end of the oval sac was continuous, by a tubular process as thick as a lead pencil, with the inner popliteal bursa This tubular process was exsected as high as the tuberosity of the tibia By means of a probe and flushing with a syringe the flattened popliteal sac was found to cover the whole popliteal space and to extend upwards a considerable distance Not having the consent of the patient and not being prepared for so important a procedure as opening the popliteal sac with the idea of a more or less complete extirpation, in view of the fact that the sac probably communicated with the knee joint cavity, I deemed it prudent to make no further dissection I swabbed the whole cavity freely with full strength carbolic acid, inserted a drainage tube and maintained elastic compression In a few days the patient went to work and the discharge of synovial fluid seemed to increase rather than diminish I then injected an ounce of the full strength carbolic acid and maintained it in the sac as long as possible, corking the tube and putting the patient at rest for twenty four hours This was afterward repeated After each treatment there would appear tenderness and effusion in the knee joint This resulted in diminishing the discharge which also became thinner but it was still sufficient to saturate a heavy dressing twice a day At this juncture (in July) the patient went to the old country and is now living in Vienna, Austria, where I learn he has since had some kind of an operation I should add that the patient complained of nothing and I observed nothing previous to the operation which led me to suspect that there was any trouble with any of the popliteal bursæ or other strictures in that region

My diagnosis is a chronic bursitis of the semimembranosus bursa possibly of tubercular origin although there were in the sac none of the "rice grain" or "melon seed bodies usually found in such cases The semimembranosus bursa is the largest of the natural bursæ Of the four popliteal bursæ it is the one most frequently enlarged In the adult it almost always communicates with the synovial sac of the joint as well as with one or more of the contiguous bursæ

DISCUSSION

Dr Gustav Fütterer—The anatomic tubercle is a warty growth of an extremely chronic character I have observed them on my own hands and on the hands of others in great numbers and for many years Here, for instance I can show you one near the tip of my index finger, on the volar side, one which needed more than ten years to reach this spot from a place on the back of the finger, about an inch distant from whence it started It will be noticed, that this tubercle has grown like most such tubercles, occurring near the end of fingers in a peripheral direction, and that it has left fine scars, representing the appearance of a net with very fine meshes

In favor of the genuine tubercular nature of those formations, I would say, that quite a number of investigators found tubercle bacilli enclosed in the tissues of the anatomic tubercle, that I have also seen them and furthermore, that I have seen tuberculosis of a hand joint originate from anatomic tubercles of the skin the latter almost covering the entire back of the hand This was in the case of a man, who for years daily prepared a number of cadavers for my work A resection had to be performed The tubercular granulations of the anatomic tubercle share another peculiarity with other tubercular granulations, and that is their fragility

Excision is not the only proper method for removing those tubercles I have had between thirty and forty of them on my hands and have successfully removed a number of them with the aid of muriatic acid, while the larger ones were successfully treated by Professor Schoenborn of Würzburg in the following way Schoenborn dipped a sharp but short-pointed glass rod into a 95 per cent solution of carbolic acid, then piercing the tubercle with it and repeating this five or six times at a sitting This procedure was very painful, but it caused the tubercles to shrink and after several treatments removed them entirely It was just then, I had occasion to observe the fragility of the granulations, for, while the point of the glass rod at first in the upper layers would find a strong resistance, later overcoming this, it would rush right through the granulations, down to the bone

Dr D D Bishop—The anatomic tubercle was examined for tubercle bacilli, but only a limited number of sections were prepared, and, of course the fact that the tubercle bacilli were not found would only indicate to us the fact that we probably did not search long enough, because the bacilli are known to be frequent in this variety of tubercle

Ludvig Hektoen, M D read an abstract of a paper on

THE VASCULAR CHANGES IN TUBERCULOUS MENINGITIS—ESPECIALLY THE TUBERCULOUS ENDARTERITIS

The genesis of tuberculous meningitis presents a great many points of interest Thus, for instance, the frequent, almost exclusive, localization of this process about the arteries of the pia mater, particularly those in the sylvian fissure, the question of the mode of importation of the bacilli into the brain, the presence of a mixed infection or not—these are all subjects of interest

Already in 1872, Buhl characterized general miliary tuberculosis, in which tuberculous meningitis often occurs, as a resorption and infection disease, likening the miliary tubercles to the metastatic abscess in pyemia, and Huguenin, in 1878, came to the conclusion that tuberculous meningitis was due to embolism into the meninges of some product produced in the older tuberculous foci which are nearly always found in the bodies of those who die from tuberculous meningitis Koch's discovery of the tubercle bacillus, and Weigert's demonstration of the way in which tuberculous foci may break into the veins, by changing the vein walls into granulation tissue, and thus flood the circulating blood with bacilli, furnished the direct evidence of what was thought to be the case

At the present time the majority of authors regard the infection in tuberculous meningitis as occurring through the blood There are only one or two exceptions to this statement Thus for instance, Babes thinks that in certain instances of tuberculous meningitis, particularly those secondary to tuberculosis of the peri-bronchial glands, the bacilli may be carried into the meninges along the deep lymphatics of the neck, by a retrograde import, and Hubbenet assumes the same route in a case described by him Then Demme and Coates have both described cases of tuberculous meningitis which may have been due to infection through the nose There seems, however, to be no question but that in the vast majority, if not in all, of the cases of tuberculosis, the bacilli reach the brain through the circulating blood, and that meningitis is secondary to some tuberculous focus in some place in the body A bona fide instance of so called primary tuberculous meningitis does not seem to have been described And yet there is really no reason why a real primary tuberculous meningitis might not originate when we take into consideration the fact, for instance, that Strauss examined twenty-seven healthy persons and in nine of these he found tubercle bacilli present on the mucous lining of the nose There is no reason why tubercle bacilli from the nose might not be carried directly into the brain by means of the lymphatics, and give rise to a tuberculous meningitis, precisely in the same way in which many forms of non-metastatic, suppurative meningitis are assumed to originate And then tuberculous bacilli have been found in the ear, and they might easily gain entrance into the meninges from that place These are only suggestions showing that a real primary tuberculous meningitis is not entirely impossible Now the opinion being so prevalent and universal that tuberculous meningitis is always of a hematogenous nature, the location of the tubercles in the vicinity of the vessels and the close connection with the vessels have been looked upon as sort of matters of course If we study the literature we find that the majority of the writers do not seem to have investigated this question very closely The exact relation of the vascular changes to localization have not been so very thoroughly investigated, we find for instance, that Rindfleisch, Zeigler, Birch-Hirschfeld, Lancereaux, Baumgarten and Guarnieri, and a number of others, all regard the localization of the bacilli as occurring almost always if not exclusively in the adventitia of the arteries, and from the adventitia the outer walls may be involved

In connection with this primary tuberculous periarteritis, there has been described, particularly by Guarnieri, but also by Baumgarten and others, an endarteritis, which has been regarded as secondary, either due to direct extension through the walls of the periarteritis, or produced in a rather indefinite way, somewhat in the same manner as chronic inflammatory processes in the vicinity of the arteries in various tissues appear to cause a proliferation in the intima, as witness the case described by Weintraud Then there are others, such as Huguenin, Huettenbrenner, Cornil and Hirschberg, who have observed a tuberculous endarteritis in tuberculous meningitis which they regard as primarily due to the direct implantation of the bacilli upon the intima of the arteries and to which many of the other lesions in the meninges are secondary

Now with this brief review of the literature before us, it is in order to summarily describe the cases which were examined in Prof Chiari's Institute in Prague Nine cases of tuberculous meningitis were studied, the technique of the examination was the ordinary histologic The only particular point to be called attention to was the fact that pieces of arteries, both large and small, were examined by means of serial sections It was found that only in this way could one gain a clear idea with reference to the mutual relations of periarterial and endarterial foci The bacteriologic examination was made by inoculating glycerin agar plates with the exudate at the time of the post-mortem In only one of the nine cases did there seem to be a mixed infection due to the staphylococcus pyogenes albus but as shown by the histologic examination this staphylococcus did not seem to have influenced the changes much The ordinary lesions characteristic of tuberculous meningitis were found In three out of five instances in which cultures were left under suitable conditions for the development of tubercle bacilli growths of tubercle bacilli were obtained In a majority of the cases, it was possible to demonstrate bacilli in cover glasses made from the fluid exudate This shows that the diagnostic measure of puncturing the spinal canal in certain obscure intracranial lesions may be of value because it may be possible to demonstrate tubercle bacilli that may be present in the cerebro-spinal fluid In two instances rabbits were inoculated with the exudate and developed tuberculosis In addition to examining the fluid in the meninges, bacteriologic examination was also made of the nose in some of the cases In these cases this examination was also limited practically to a search for tubercle bacilli In two out of five cases that could be examined in this way tubercle bacilli were found in small numbers Inasmuch as these cases were instances of multiple chronic foci of tuberculosis, the exact significance or source of the bacilli found in the nose can not be stated Gradenigo examined the contents of the internal ear and of the pharynx, and also the nerves that pass through the ear, and in a number of instances of tuberculous meningitis he found tubercle bacilli in these places, and he regarded these bacilli as passing out from the cranial cavity along these routes

Concerning the arterial changes, it may be said that in addition to the ordinary extra-vascular lesions, which are familiar to all, it was possible in all the cases to demonstrate changes in the intima of the smaller of medium sized arteries that have to be regarded as primary and as due to the direct implantation of tubercle bacilli into the intima The lesions that result from such implantation take two forms that are frequently combined but often singly present There may be a diffuse tuberculous endarteritis, consisting of a proliferation of epithelioid cells located underneath the endothelium, between the latter and the elastic lamina In addision to this diffuse tuberculous subendothelial proliferation, which sometimes exists to such a degree as to close practically the entire lumen of the artery, there were also found isolated miliary tubercles upon the intima In some instances giant cells were found in the diffuse tuberculous proliferation just mentioned, but without such an arrangement of the surrounding cells that the appearances could be characterized as a typical tubercle The more typical internal tubercles, however, did not present any special variations from ordinary tuberculosis When caseation was present in the intimal tubercles the endothelium over the tubercle would be absent In many preparations, including pieces of arteries in which there were no other changes except those located in the intima, it was possible to trace the process in its progression outward The cell proliferation penetrated and split up the elastic layer and infiltrated itself into the media In some instances the ends of the elastic layer were bent outward and the media had become so much weakened that a slight bulging in the artery was produced, so that there were appearances that could be likened to small aneurisms In addition to these intimal changes that leave no other interpretation regarding their origin open except that they are due to implantation of tubercle bacilli upon the intima, there are more diffuse changes which in many cases must be regarded as having proceeded from periarterial foci, on the other hand it may be concluded that at times they had proceeded from the endarterial lesions Tubercle bacilli were found in small numbers in the intimal lesions and frequently in immense numbers in the adventitial foci and in the walls of diffusely changed arterial segments Regarding the veins in tuberculous meningitis, the following broad statement can be made, viz That in every instance there is a marked, diffuse and extensive phlebitis, with giant cells and granulation tissue growing out into the lumen of the vein and causing there a parietal or, often, obliterating thrombosis

Experimental tuberculous meningitis has been produced by Deutschmann and Darenberg, and more particularly by Tedeschi The latter worker experimented with a large number of various kinds of animals, particularly rabbits, dogs and guinea pigs, and was able to produce a diffuse meningitis, usually accompanied by changes in the cord and brain But, inasmuch as no one seemed to have attempted to produce a tuberculous meningitis by means of direct injection of tubercle bacilli into the arteries, the following experiments were made

A suspension of tubercle bacilli in bouillon or in sterilized water was injected directly into the carotid artery of a rabbit and so far as the experiments have gone—they are not as yet concluded—it has been found that a meningeal miliary tuberculosis can readily be produced in the rabbit by this method On the other hand it has not been possible thus far to produce a typical meningitis in rabbits The lesion in rabbits simply takes the form of a miliary tuberculosis, without the exudate which is characteristic of tuberculous meningitis in man In the specimens which have been examined from rabbits the lesions have all been so large, that the exact relations of the process to the various layers in the arterial wall have not been demonstrable The lesions have been found in close connection with the arteries The arteries have usually been entirely obliterated by granulation tissue, but caseation had proceeded so far that the exact relation of the endothelial lining to the process could not be determined

The changes observed in the arteries in tuberculous meningitis may be summarized as follows There is found a primary tuberculous endarteritis which is due to a proliferation of epithelioid cells underneath the endothelium, between the endothelium and the elastic layer, this proliferation may extend to such a degree as to practically obliterate the vessel As it becomes advanced, leucocytes appear among the epithelioid cells, but in the early stages it consists of pure epithelioid cells, that is, cells with rather large bodies and small nuclei In addition to this primary tuberculous endarteritis there may be limited intimal tubercles These may be present singly or they may be present in conjunction with the diffuse endarteritis These intimal changes may proceed outward and invade the remaining coats of the vessels, and having reached the adventitia, the process may be spread throughout the meninges by means of the crebro-spinal fluid and the lymphatics

In addition to these changes we can trace from within, there are, of course, the better known and more extensive ordinary extra arterial or adventitial changes, which may proceed inward and invade all the coats of the artery, and produce also changes in the intima The changes in the intima produced in this way, however, are not so extensive nor so well marked as the primary intimal changes to which your more particular attention is directed

There remains to consider the origin of the epithelioid cells found in this sub intimal proliferation in tuberculous meningitis The authors, especially Baumgarten, as well as Brodouski, Guarnieri, Cornil and Hirschberg that have observed these changes and described them more or less fully, trace the epithelioid cells to the endothelium, and maintain that they are produced by the proliferation of the endothelial cells lining the vessel Baumgarten, in his classic work on histology of tubercle, maintains with reference to tubercles growing in the intima of the pulmonary arteries as well as elsewhere, that they are produced by proliferation of the endothelial cells

It will be observed that the appearances in the specimens presented are in direct opposition to these views of Baumgarten and others, because the specimens show the endothelium to remain intact and unchanged until caseation has commenced in the intimal tubercles, and then the endothelium is absent The shape alone of the epithelioid cells described does not allow any inference as regards their origin, but the fact that the endothelial lining remains absolutely undisturbed in the shape of a single layer covering the cells of the proliferation, seems to be a very strong argument against the theory that the epithelioid cells originated from the endothelium, because if the endothelium should proliferate, if, for instance, one single endothelial cell should divide it would result in the displacement of the cell with regard to its relation to the other cells constituting the endothelial lining of the vessel On the contrary, the endothelium remains not only passive, but even resistant to the process, because it is present even when the endarterial proliferation has reached such a degree as to bring the endothelial lining in contact in the central part of the vessel, as you will see in the specimens under the microscope Consequently the conclusion seems justifiable that the subendothelial proliferation of epithelioid cells that occurs in the tuberculous endarteritis of tuberculous meningitis does not come from the cells of the endothelial lining of the arteries, but more likely from the subendothelial connective tissue, which is present in such arteries, into which the tubercle bacilli, circulating in the blood, are forced, the bacilli passing between the endothelial cells which remain resistant to their influence until subendothelial caseation occurs

DISCUSSION

Dr J B Herrick—Mr President and Gentlemen of the Society—It was my privilege through the kindness of Dr Hektoen, a few days ago to read in full the paper of which he has given this admirable abstract After reading Dr Hektoen's paper, and noting the details of the histologic examinations, and after studying his drawings and the beautiful microscopic preparations here presented to us, one is forced to believe that his conclusions are warranted, and that we may look upon it as an established fact that there may be a primary intimal tuberculosis, as well as a primary infection of the vessel wall through the adventitial lymph channels

While Dr Hektoen's paper is one of a purely histologic and pathologic character, it is not amiss, I think, to call attention to certain practical results that follow directly from the knowledge that his investigation gives us In fact, we may say, in passing, that a purely scientific result, a result that is purely pathologic, histologic, or anatomic, is of very little positive value, unless something practical can be derived from the knowledge thus acquired, unless the result obtained helps us the better to understand the phenomena of health or of disease, or aids us in the rational treatment of bodily ailments

There are certain cases of tubercular meningitis that are sometimes spoken of as cases of anomalous or abnormal meningitis Hirschberg has collected the histories of these cases (Deutsches Archiv für Klin Med xli 528) In this anomalous form of meningeal tuberculosis, the onset is sudden and with symptoms that may resemble very closely those of cerebral hemorrhage The symptoms are focal There may be a Jacksonian epilepsy, a hemiplegia, an aphasia, and the practitioner's attention is scarcely called to the possibility of meningeal tuberculosis until after the lapse of several days when ordinary symptoms of a meningitis appear At the autopsy in these cases the amount of exudate may not be sufficient to explain the focal symptoms, nor are they explained by the presence of a large solitary tubercle, nor by ventricular exudate or by cerebral edema But there is an area of cerebral softening, usually on the convexity This softening is the direct result of the tuberculosis of the wall of some of the cerebral arteries The tubercular mass may bulge into the lumen of the artery and occlude it, or a thrombus may form at the constricted portion, the result in either case being a cerebral softening that may, in case the vessel is of sufficient size and without anastomosing branches, produce marked focal symptoms The process in this case would be a simple encephalomalacia

In a second group of cases this softened mass in the encephalon is itself tuberculous—tuberculous encephalitis And when we think that between the tuberculous mass in the wall of the artery and the lumen of the artery, there is in so many cases but the thin barrier of the layer of endothelial cells, it is a cause of wonder that oftener the mass does not break through the endothelial lining, in this way liberate into the blood current the bacilli, and flood the little area of the brain that is supplied by that artery, thus producing a localized tubercular encephalitis

In a third group of cases, the focal lesion may be a softening, the result of arterial occlusion through endarteritis obliterans induced by a neighboring subacute or latent tubercular process This origin of obliterating endarteritis is in accordance with the investigations of Friedländer Weintraud, to whom Dr Hektoen refers, reports a case of this kind A localized unilateral hyperesthesia and a monoplegia preceded for some days the onset of recognizable symptoms of tubercular meningitis of the meninges, and in its immediate vicinity an artery with marked endarteritis obliterans—no tubercle bacilli, no giant cells, but abundant young fibrous tissue—thrombosis, and resulting encephalomalacia

In cases, therefore, in which we can exclude a valvular disease, which practically excludes embolism, in cases where we can exclude an abscess or tumor of the brain, in young persons the walls of whose arteries seem to be perfectly healthy and not predisposed to hemorrhage, and particularly in a young person in whom we find some tubercular focus in lung, gland, or bone, we should always remember that a sudden seizure with hemiplegia, a monoplegia, a Jacksonian epilepsy, an aphasia, or some local sensory disturbance, in other words, a suddenly developing focal symptom, may be the initial symptom of a case that will later run the course of an ordinary tuberculous meningitis

Dr Gustav Fütterer—Dr Hektoen's paper is an excellent one and the microscopical specimens which he showed, proved conclusively every assertion made in his paper in all its details The fact that Dr Hektoen has made his examinations of the blood vessels of the pia mater in continuous series, gives him a valuable advantage, enabling him to form precise ideas on each tubercular change itself and on its relations to other tubercular changes surrounding it, that means here especially the relationship between the tubercular new formations in the tunica intima, the tunica media, and the perivascular sheath Dr Hektoen's opinion, that the miliary tubercle of the intima does not originate from the endothelial cells, but rather from the subendothelial layers, seems to be well founded and after examining his specimens, I rather believe, that in the near future, he will be able to furnish sufficient proof of this, because these blood vessels are the best material for such examinations, as the lamina elastica cannot furnish the material for the miliary tubercle and only the endothelial cells and the subendothelial layers have to be considered

Dr Hektoen has shown that the tubercle of the intima can be found in the majority of cases of tubercular meningitis and necessarily further anatomic and clinic inferences must be drawn from this Those tubercles—if located in smaller vessels, may cause obstructions, which, when present in arteries, will bring about an anemia of the parts which they supply, or if located in veins, a venous stasis will be followed by an atrophy, while a breaking down of those tubercles would cause a general miliary tuberculosis as Weigert has described it in similar changes of the veins of the lungs

As Dr Hektoen intended to deal with the endovasculitis and mesovasculitis, I will take the liberty to say a few words about the tubercular changes of the perivascular sheath, which are predominant in all cases of tubercular meningitis and deserve our due consideration A cross section of a blood vessel of the pia mater shows us a tube in a tube, the inner tube consisting of intima and media, the outer of adventitia and the space between both representing the lymphatic space The miliary tubercles are located on the outside of the perivascular sheath like beads around a ring, this is the case in the pia mater, where no resistance is offered to the growth of the tubercles in a peripheral direction Consequently, those will neither press on the perivascular lymph spaces, nor on the blood vessel itself, but we see their cells proliferate into the lymphatic space and infect the media, thus causing a mesovasculitis, which is of the highest clinic importance, as it causes a rigidity of the blood vessels, which prevents their full contraction and the proper propulsion of the blood current

In the brain substance the above described process is about the same, but the tubercles find a much greater resistance by the compact mass surrounding them and they grow in the direction of the blood vessel, which they compress and which thus becomes involved in the tubercular process much sooner than the vessels of the pia mater This involvement is then, as a rule, represented mainly by a mesoarteritis, or a mesophlebitis, while the lamina elastica forms a barrier against the infection from outside, even, as a specimen which I have with me will show you, until infiltration and pressure close the lumen of the vessel entirely This latter fact, together with Dr Hektoen's observation that the endothelial layer over the intima tubercle, remains intact, gives a further strong support for his opinion on the histogenesis of those tubercles

I said before that the rigidness of the vessels is of great importance, but this importance varies, according to the seat of the process and I would propose to classify as follows

1 If the diffuse process is located along some larger arteries, for instance, around the arteria fossae sylvii, a larger territory will be deprived of a part of its nutrition and anemia and atrophy may follow, as we find it in atheroma

2 The affection of small vessels of the pia mater causes atrophy of the marrow substance of the nerves, which we find in the outer portions of the cortex and a diffuse lessening of the same substance in the deeper layers of the cortex and of the adjoining portions of the white substance

3 If the vessels of the cortex are affected, the atrophies are comparatively small, on account of the rich blood supply of these parts, in which we find a dense net of small blood vessels, which has its smallest meshes wherever there are the most ganglion cells, so the ganglion cells are well supplied

4 On entering the marrow or white substance of the brain, the meshes of the capillary net become much longer and wider and the poor blood supply in those parts is easily disturbed by the vascular process described, the more so, as a total obstruction of vessels comes about so easy

Tuberculosis of the pia mater can heal I have examined a case of Leube, in which he had made the diagnosis of a tubercular mningitis and to his surprise the patient recovered Leube could not doubt his diagnosis Two years later the patient died of a tubercular cerebral meningitis I then made a detailed examination which revealed old cicatrized miliary tubercles along the vessels of the pia mater spinalis, sprinkled with calcareous deposits, the latter showing that the tissues were dead I have demonstrated those specimens in the Medico-physical Society at Wurzburg and have published drawings of them in the year of 1890

Amendment to the Constitution

(Offered by Dr H Bert Ellis, at the Baltimore meeting and by *inadvertence omitted from the minutes*)

Amend Article II, page 7 to read as follows Members by invitation shall consist of practitioners of reputable standing, not connected with affiliated societies They shall receive their appointment by invitation, etc

NECROLOGY

WILLIAM COMPTON, of Lancaster, Penn, December 15, of pneumonia He was born in 1825, at Cambridge, Lancaster County, was graduated from the Philadelphia Medical College in 1853 After serving as resident physician in one of the city hospitals, he went to Lancaster and began practice over fifty years ago, where he remained until his death He was at various times physician to the county prison and almshouse, coroner's physician and one of the local physicians to the Pennsylvania Railroad Company He had been president of the Lancaster County Medical Society and for many years was a member of the AMERICAN MEDICAL ASSOCIATION

SAMUEL FLEET SPEIR, M D, of Brooklyn, died December 19 aged 56 years, from hemorrhage of the stomach, probably due to a malignant growth affecting that organ and the liver He was a native of Brooklyn, the son of Robert and Hannah Speir On his mother's side he was a descendant of Captain Thomas Fleet, a retired Royal Navy officer, who settled on Long Island about 1660 Dr Speir received his medical degree at the New York University in 1860, taking the Mott gold medal, also the Wood and Van Buren prizes He was a thorough anatomist and for a time served as demonstrator at the Long Island College Hospital He studied abroad, after graduating, giving special attention to surgical clinics In 1864 he took the prize medal of the AMERICAN MEDICAL ASSOCIATION for an essay "On the Pathology of Jaundice" In 1871 he took the prize of the New York State Medical Society by an essay in which was described his device, called an artery-constrictor, for the arrest of surgical hemorrhage without the use of a ligature In the same year he read a paper before the New York Academy of Medicine on the microscopic differentiation of morbid growths He was physician to the Brooklyn Dispensary curator, microscopist and surgeon to the Brooklyn Hospital, also surgeon to the Eye and Ear Infirmary He was one of the originators of the Seaside Home for children and a benefactor of many charitable undertakings He was a collector of exotics and other rare plants, and was a lover of fine dogs and Alderneys His kennel of hunting dogs had many a prizewinner He was a member of a number of medical and social clubs and societies, and the founder of one of the best of the sportsmen's seaside homes, known as the Robins' Island Club He leaves a widow and one daughter

Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE INCLUDING POSTAGE
PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 86 FIFTH AVENUE, CHICAGO ILLINOIS
W H LOWDERMILK & CO WASHINGTON AGENT

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, Venetian Building Chicago Ill, sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor* and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION 86 Fifth Avenue, Chicago

SATURDAY, DECEMBER 28, 1895

FILTRATION AS A MEANS OF IMPROVING THE WATER SUPPLY OF CITIES AND TOWNS

A long step in the settlement of this important question has been taken by the State Board of Health of Massachusetts By the Legislative act of June 9, 1893, the State Board was directed to "investigate, consider and report upon the question of a water supply for the city of Boston and its suburbs within a radius of ten miles from the State House, and for such other cities and towns as in its opinion should be included therewith"[1] The result of the act, was the production of the exhaustive report of February 7, 1895

In that report filtration of Merrimac water was considered as less desirable than to introduce a satisfactory water from another source The report states (p xv) "Examinations have also been made with the view of taking the water of the Merrimac River above Lowell, subjecting it to efficient filtration and bringing it down to the metropolitan district The quantity of water that could be obtained in this way and for this purpose is unlimited, and if there were no way of obtaining a better supply of water and one which was above suspicion, it would be practicable to introduce water from that source at a cost somewhat less than from any other source considered

"The estimated cost of filtering and conveying this water to the metropolitan district is $17,500,000, but in the opinion of the Board it will be better to pay 10 per cent more from a source that is not polluted The experiments carried on by this Board for a succession of years at an experiment station in Lawrence under the immediate direction of H F Mills, C E, a member of this Board, and the filter constructed in connection with the waterworks of that city, have shown that waters as polluted as those of the Merrimac can be effectually filtered and rendered safe for domestic use, but it is also true that filtering areas require continuous care on the part of trained attendants, and that in a few instances at least, inefficient administration or inherent defects of construction have allowed disease germs to pass through filters which were assumed, by good authority, to be a sufficient protection We are the more easily led to reject the filtered waters of the Merrimac because we have found an entirely satisfactory water in the south branch of the Nashua River above the city of Clinton"

The report further states (p 104) "The most feasible way of purifying a water like that of the Merrimac River is by filtering it through sand, a method which has been tested at the experiment station of the State Board of Health at Lawrence for many years, and has been in actual use for filtering the public water supply of this city for more than a year At this place a sand filter was completed and put in operation in September, 1893 It has an area of two and one-half acres, and consists of a bed of sand about five feet thick, through which water is filtered at a rate not exceeding 2,000,000 gallons per acre per day The sand was very carefully selected with a view to having its grains of such a size that they would remove from the water the germs of typhoid fever The practical results obtained with this filter have been very satisfactory, indeed, as there has been a very great reduction in the death rate from typhoid fever and some other diseases in Lawrence since it was put in operation"

This system was devised by the Board in 1890, and was the result of "strenuous efforts to produce a filter that would remove all disease-producing germs that could be applied to it, and at the same time filter rapidly enough to serve for a city's water supply Billions of typhoid germs were cultivated and applied to filters of different construction, and in 1891 we succeeded in removing all that were applied when filtering 2,000,000 gallons per acre daily[2]

In the current annual report the Board practically concludes the subject by the details of its experiments extending over a period of seven years and including the results of more than thirty thousand bacteriologic analyses[3] After considering the subject of the filtration of sewage, the report continues the discussion of the great hygienic problem of purification of the sewage-polluted waters of the State by sand filtration The statistics of the work of thirty experimental filters are given, in addition to those of the large filters at Lowell For the sake of greater accuracy the report uses some new technical expressions which are self-explanatory

[2] Annual report Massachusetts State Board of Health 1893, p 546

[3] Annual report Massachusetts State Board of Health, 1894, pp 575–710

a Bacterial efficiency
b Bacterial purification
c Hygienic efficiency

"The question of hygienic efficiency of filtration," says the report, "in a great majority of cases is the vital one to be considered" The subject is concluded by an interesting paper by MR H W CLARK on the physical and chemical properties of sands with special reference to the filtration of water, in which some of the facts that have been brought out by the long continued observation are reported

As to intermittent and continuous filtration, the Board says, p 653 "Intermittent filtration is successful in the chemical purification of all waters containing ordinary organic matter Chemical purification by continuous filtration is successful only *in the case of those waters which do not contain* organic matter in excess of a certain limit determined by the relation of the organic matter to the free dissolved oxygen, which is limited in quantity by the saturation point" The Board, however, goes further than this (p 645) "It may be stated that so far as the amount of ordinary organic matter and free oxygen are concerned, satisfactory *bacterial* results may be obtained under proper conditions from the intermittent filtration of any water even when its composition approaches that of sewage"

It is quite clear from an examination of the investigations of the Board that filtration under such conditions as those in operation at Lowell, is a hygienic measure of the highest importance, and it is not probable that in this country generally we shall ever attain the best results that applied hygiene can furnish until the rule is absolute, that all public water supplies shall be filtered It seems, too, that the "bacterial efficiency" and "bacterial purification" of water filters increase with age (p 597), a rather important fact in its bearings upon the economic value of a proper filtration plant

To those municipal authorities engaged in the study of this question, we commend the careful examination of the 1894 report of the Massachusetts State Board of Health as the most exhaustive, thorough and complete report on the subject

HEREDITY IN RELATION TO INSANITY AND IDIOCY

The opinion that a neurotic inheritance is the chief predisposing cause to insanity is now very generally held Some alienists are disposed to go even further, and declare that it is mainly to the orignal constitution of the brain that we must look for the first and chief cause of mental breakdown, the ordinarily assigned causes being none of them, in themselves, sufficient to bring on insanity It can scarcely be called into question that what is called rather indefinitely "the neurotic inheritance" does render the brain more liable to be affected by such proximate causes, and the belief is now general that, whether we can discover the fact of such inheritance by outward and visible sign or not, its existence and evil influence are indisputable Indeed, the opinion has by a recent writer been rather dogmatically expressed in the statement that "the condition common to all mental disturbance is to be sought in inherited and inherent brain-defect" This is exclusive of the forms known as septic or toxic insanity and those instances of aberration of mind symptomatic of cerebral exhaustion, traumatism, and other pathologic lesions

In view of the present etiologic importance assumed by this neurotic inheritance, or hereditary predisposition, it would be well to define this condition and determine its definite relationship to insanity and idiocy The views of a distinguished German alienist are pertinent to this consideration and may be briefly quoted In the preface to his work on Psychiatry, *PROF THEODOR MEYNERT* expresses dissatisfaction with the statistical method, which, in his opinion, has laid inordinate stress upon hereditary predisposition, and which broadly teaches that predisposition itself is a form of disease and not a condition antecedent to it Nor is he content to accept what he terms the "mystical conception of heredity," but he insists upon certain anatomic peculiarities in patients which constitute this predisposition The existence of such peculiarities are to be inferred not only from symptoms and external signs, but also from due consideration of all abnormal proportions of the body The doctrine of heredity, according to MEYNERT, is carried to an extreme in the assumption of the existence of innate ideas and, in clinic medicine, has led to the erroneous theory of moral insanity With DUBOIS REYMOND and WEISSMAN, he criticises DARWIN's theory of acquired faculties, and quotes approvingly WEISSMAN's words, "Talents do not depend upon the possession of any special portion of the brain, there is nothing simple about them, but they are combinations of many and widely different psychical faculties" At the same time, MEYNERT fully recognizes the possibility of an abuse of the doctrine of inherited anatomic peculiarities and of hereditary predisposition, even from the standpoint of actual fault of organization as its tangible basis, on account of the constant suspicion of mental defect attaching thereto But he reminds thinking physicians that they may avoid this danger by distinguishing between the many who are possibly called to disease and that fortunately smaller number of persons, who are, in the saddest sense of the term, chosen for disease

The following conclusions upon this subject have been formulated at our request by DR JOHN B. CHAPIN, a distinguished American authority, now in charge of the Pennsylvania Hospital for the Insane at Philadelphia

1 Physical characteristics, those distinguishing the human species for instance, are transmissible by inheritance

2 Knowledge, genius, culture, being dependent on the influences of education and environment upon the individual, are not transmissible, but what may be termed mental receptivity, and degrees of cerebral evolution and development, may be inherited Psychic qualities are not necessarily an inheritance, as they require favorable surroundings and circumstances for their growth and development

3 Insanity, as a disease, is not transmissible by inheritance but may be acquired or evolved, especially where a neurotic heredity exists as a basis

4 A neurotic predisposition is transmissible by inheritance, but there is no absolute rule that it will be transmitted in every case

5 As regards the formation of a neurotic heredity, the in-breeding of neurotic temperaments is most conducive to its creation

6 Idiocy and imbecility may be the resultant of certain defects having origin in consanguineous marriages, in pre-natal conditions, accidents, arrested cerebral development, infantile meningitis, tuberculosis, and lack of potency on the part of one or both of the parents from unexplained causes

Premature closure of the sutures in the cranial vault has also been recognized as a cause of imbecility, and for the relief of this condition linear craniectomy has been proposed and performed, without, however, a gratifying amount of success Indeed Bourneville asserts that the theory of Lannelongue in regard to craniotomy in microcephalus has no anatomic and physiologic basis, in fact, and that the operation should be banished from the list of justifiable surgical procedures It is clear that a distinction is to be made between those microcephalic cases in which there is premature synostosis with arrest of cerebral development, and those in which the head is small because the brain itself is small Among the unexplained causes of lack of potency on the part of one or both parents alcohol may be placed, according to very prevalent popular belief Not only may the mental endowment of the child be unfavorably influenced by acute alcoholism at the time of conception, but also the cerebral changes and nerve degeneration, and inflammation, resulting from chronic alcoholism are distinctly prejudicial, from the standpoint of heredity

To broach the topics of degeneration and atavism would take us beyond the limits of the present article, although they are closely related to the subject of the relation of heredity to insanity and idiocy But to sum up the foregoing, it is evident that Meynert recognizes an anatomic peculiarity, which may or may not manifest itself by symptoms of aberration Chapin holds that neurotic instability may be transmitted by inheritance, yet it is capable of exerting only a potential influence in the later development of mental disorder, which may be evoked by social condition, environment, or pathologic changes in the cerebral cortex Imbecility and idiocy, however, may directly result from defective cerebral development or pre-natal disease

The whole subject of the etiology of insanity is a complex and difficult one, and, as pointed out by Holland some fifty years ago in his "Medical Notes and Reflections," it is rendered more abstruse by the fact that the pathologic change may be so minute as to defy the search of the pathologist, although sufficient to produce disturbance of intellection, while, on the other hand, great organic changes in the brain are not incompatible with the occurrence of a lucid interval, which, if we are not on our guard, may lead us to entertain false hopes of recovery

THE ANTISTREPTOCOCCIC SERUM

Marmorek, in a recent article,[1] gives the results of his experiments in obtaining a serum with which to combat infection by streptococci The microbe loses its virulence very rapidly when cultivated in artificial media, hence his first effort was to secure a suitable culture medium It seems to grow most favorably in a mixture of two parts of human serum with one part of beef bouillon As the former is difficult to obtain, ascitic fluid was used and finally one part of this fluid and two parts of the bouillon adopted To enhance the virulence of the microbe, the author first made a culture of streptococci from an angina in bouillon, then blood, taken from a rabbit killed by intravenous injection of this culture, was inoculated from the same culture Part of this was injected into another rabbit, which died in eighteen hours, another culture made and injected into a third rabbit, which died more rapidly, and so on Finally, by successive passages, Marmorek obtained a microorganism of such extreme virulence that a culture in the dose of one one-hundred-millionth of a cubic centimeter was inevitably fatal Having obtained these results, and the streptococci found in the human organism being identified, the next step was to obtain immunity in animals Several methods have been suggested, among them injection of cultures sterilized at 120 degrees, or injection of living and very virulent cultures The author made use of the latter methods Efforts are made to immunize the largest animals—the ass, horse and sheep The ass bears the inoculations very badly Whichever animal is selected a very small dose must be used to commence with, for one cubic centimeter will produce a marked reaction, the quantity may be increased slowly, but it takes a long time to secure the inoculation—at least six months Horses immunized against diphtheria support these inoculations better than fresh animals It is possible that serum may be produced which is both antidiphtheritic and antistreptococcic Three or four weeks must elapse after the last inoculation before the serum is used, so as to be sure that all reaction has subsided It will be noticed that there is a marked difference between this method and that of Behring and Roux The latter authors use toxins and not virulent antitoxins Marmorek has been unable thus far to isolate the streptococcic toxins, and serums collected from animals inoculated progressively with filtered or sterilized cultures does not possess very manifest antitoxic properties

---

[1] Ann de l Inst Past, 1895, No 7

The preventive process of the serum is well marked in animals For instance, a rabbit weighing 1,500 grammes and given an injection of 0 c c 2 of the serum will, in twelve to eighteen hours, withstand a dose ten times the mortal one of the streptococcic virus In the various streptococcic affections of human beings, the serum has not given satisfactory results as yet Thus in erysipelas, injected in the dose of 10 to 20 c c, according to the gravity of the case, it seemed to produce an amelioration of the general state In 413 cases the mortality was 3 87 per cent, which is but little less than that usually found—5 to 6 per cent

Roger read a paper on "Immunity Against the Streptococcus" before the French Congress of Internal Medicine Two principal theories have been advanced, he says,[2] to explain immunity One invokes the phagocytic action of the leucocytes, the other the bactericidal power of the fluids The previous researches of this author did not seem favorable to the last hypothesis He showed that microbes developed with the same facility in the serums of vaccinated as in that of fresh animals Pursuing his studies he found that microbes from the serum of vaccinated animals had lost the greater part of their virulence—they were attenuated The results obtained in these experiments were disputed It was said that the author's cases showed not an attenuation but a therapeutic action exercised by the serum which was injected at the same time as the microbe

In order to convince the skeptics Roger undertook a new series of experiments, which he asserts refutes all objections He inoculated three rabbits One received a culture of streptococci and succumbed in three days, the same received the same quality of the culture, but one c c, of serum was afterward injected, this lived five days, the third animal was given the same amount of culture and serum, but after being mixed it either lived or died very late Hence the serum does not act on the organism, it acts on the microbe M Roger, who was the first to point out the value of antistreptococcic serum, does not deny its therapeutic effect, but believes it is due to the attenuating action The attenuating property does not belong to the serum only, it is found in the blood circulating in the vessels Repeating the experiments made in the serum by using blood transfused so rapidly (15 or 20 seconds) that it had no time to undergo the least alteration, exactly the same results were obtained These experiments clear up the mechanism of immunity It can readily be conceived that microbes coming into the vaccinated blood rapidly lose their noxious action by becoming an easy prey for the phagocytes

THE JOURNAL IN 1895 AND 1896

At the close of another year of the Journal's existence it is fitting that a few words should be said as to its past and its prospects for the future This is a custom that is honored in the observance, when it can be well done and there is a creditable past to review, and a future for which an honest promise of still better things is possible

The Editor of the Journal feels no hesitancy in referring to its past from the day of comparatively small things in its incipiency, to the present, when it is unquestionably the largest medical publication in this country and is only exceeded by two or three in other lands In the present half-yearly volume there are nearly twelve hundred pages of closely printed matter, and while mere bulk is not in itself a merit, it is believed that the quality of the contributions and other literary material has been, on the whole, not inferior to that in any other medical periodical The Journal is now in a position to command the best scientific thought in the medical profession in this country, as a glance at the list of contributors will show A review of the work of the Sections as at present organized in the Association, will demonstrate that, from that source alone, a very large number of papers from the leading men in each specialty of medicine have the Journal as the medium of their publication It is believed that with the plans now adopted, and with its daily increasing circulation (over eight hundred increase during the past year), the Journal will become more than ever the choice of the leaders of medical thought, both through the Association and otherwise, for communicating their ideas and discoveries to the profession While it is the organ of no specialty and neglects no branch of medical science, it has probably had during the past year in its columns more original articles on certain special departments of medicine, than have appeared in some journals devoted to them alone within the same period

A special effort has been made to report as fully as possible the proceedings of the higher grade of medical societies, more especially those which, notwithstanding the merits of their papers and discussions, are not so likely to receive adequate notice from the leading journals of the Eastern section of our country The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION belongs to no section and has not limited itself in this respect to any particular region of the United States, but it is natural and appropriate that it should give some special attention to medical matters in the great central region which comes less directly under the view, in this respect, of the widely circulated medical periodicals of the East

---

[2] Le Bulletin Med 1895 No 78

In its editorial columns it has been the aim to present living questions in medicine in a judicious and, on the whole, a conservative way, especially where there is room for reasonable differences of opinion While this conservatism at times may not accord with the individual views of members of the profession, it is believed to be the wisest policy and it has been abundantly justified by events in the past Enthusiasm is an admirable thing in medicine as elsewhere, but the scriptural injunction to prove all things, is in medical as in religious matters an essential preliminary to holding fast that which is good The Hippocratic maxim that "experience is fallacious" is our surest protection against going wild over "*propter hoc*" cures

A good weekly medical journal is an essential to the progressive practitioner of medicine, it is only by such an aid that he can keep in touch with the scientific advance of his profession Text-books, hand-books, systems of medicine, and cyclopedias all begin to deteriorate as scientific guides from the date of their publication, but a good medical weekly is always at the front line of medical progress It is the aim of the JOURNAL to be behind none of its contemporaries, as an exponent of the actual state of medical science throughout the world

The promise for the future must be taken from the performance in the past The JOURNAL will take no backward steps

CORRESPONDENCE

Shall We Continue to Sterilize Milk for Infants

To the Editor —Your editorial under the title "Overdone Sterilization," in the issue of December 14, appears to me very timely As an early, consistent and persistent advocate of the germ theory in connection with many diseases, I yet feel that we are too much in danger at the present time of forgetting that there are other causes of disease than micro-organisms The possibility that the exclusive use of sterilized milk as a food for infants, while it would avoid the dangers arising from the occasional presence of the bacteria of typhoid fever tuberculosis and other infections, may prove a serious obstacle to assimilation and nutrition and thus lead to the development of rachitis, scurvy and other allied conditions of mal nutrition, as suggested in the recent article of Dr Starr, to which you refer, was pointed out by me in a paper read before the meeting of the American Orthopedic Association, at Washington, D C, May 30, 1891, on the subject of rachitis I quote from this paper as follows

'*In conclusion I would call attention to the fact, which I think I have observed, that rickets and its congener scurvy in infancy, have within the past few years been decidedly on the increase In point of fact, if one looks over the textbooks on the diseases of children written forty or fifty years ago, he will fail to find the slightest reference to the last named disease And this notwithstanding the fact that our fathers in medicine saw it twenty times in the adult where we see it once Manifestly it was not for want of familiarity with its symptoms that they failed to recognize it as one of the infantile diseases Indeed we need hardly go back more than ten years to find medical literature barren of allusions to this subject To what are we to attribute this somewhat sudden increase in diseases of defective nutrition? Is it simply a coincidence that this condition has devloped simultaneously and pari passu with the introduction of the practice of the sterilization of milk? One curious feature of this increased development of these affections is that we meet it not among the poor, not among those whose hygienic environment is faulty and whose food supply is insufficient or of inferior quality, but among the children of the wealthy who live under the most favorable conditions with strictest attention to hygienic precautions and an abundant supply of the richest milk Let us consider for a moment the part which ferments play in the preparation of food for digestion and assimilation We know to how great an extent the digestibility of the great staple of life, bread, is increased by the development in the flour of the saccharomyces cerevisiæ, how beer in its various forms becomes a wholesome drink through the action of the same ferment, how the vinous fermentation furnishes us healthful beverages and useful stimuli and how the acetic fermentation supplies us a most valuable condiment We also know that of all the ferments none approaches so near the fluid known as the gastric juice as lactic acid We know what a wholesome and nutritious article of diet milk becomes in the shape of curds and whey, buttermilk cheese and matzoon, after having been acted on by the lactic acid ferment We know that under all ordinary conditions milk contains the lactic acid bacterium Now is not the supposition warranted that up to the point when this ferment has been developed in milk to such an extent as to produce an acid taste which leads most persons to dislike it, its action on that fluid may be in the highest degree favorable to its digestibility and assimilability? Moreover, may not the lactic acid have a very important function in taking up the lime salts and, in combination with phosphoric acid, putting them in condition to be absorbed by the lacteals and appropriated by the system The fact that sterilized milk is indigestible no one questions May we not be denying our infants some of the most important of the constituents of milk, allowing them only the fats while we deprive them of the salts? To atone for presenting them a less digestible milk we pre digest it before giving it, thus depriving the stomach of the natural stimulus afforded by the presence of food requiring digestion, discouraging the secretion of the gastric juice, and still further interfering with the assimilation of the mineral constituents Do we not perhaps need to revise our recent conclusions on the subject of infant diet and sterilization of milk?*'

I observe that that eminent authority, Prof A Jacobi, in the leading article of "Pediatrics" for January, 1896, in which he reviews the question of infant feeding at length, while urging the importance of the sterilization of milk in the strongest possible terms, yet calls attention to the fact that "sterilization has been claimed to be no unmixed boon because of its changing the chemical constituents of milk"

In speaking of the method of Dr Rotch, which consists in sterilization, mechanical separation in order to remove impurities, and remixture of the milk and cream, he says

"I know of a number of babies who in health and disease have done well on the protracted use of the laboratory milk Only one observation struck me in a few cases The formation of the muscles and part of the bones appeared to be slow, the teeth came a number of weeks or even months too late the cranial bones turned slightly soft in a few instances In a few such cases I had to add animal broths or juice before the usual time, in one I tried phosphates, (elixir phosphori) which was rejected, in others it was well borne and useful"

For myself I am not prepared to admit that the lactic acid ferment is, up to a certain point, injurious, or indeed that it may not on the other hand be essential to the full digestion and appropriation of milk It is a well known fact that certain tribes in Africa who subsist largely on milk never, under any circumstances, drink it until it has begun to sour, their experience having taught them that the use of fresh milk is very apt to result in the development of fevers When circumstances, such for instance, as residence in large cities, make it necessary to adopt means to prevent the lactic acid fermentation from proceeding to the stage in which an acid taste is developed, up to which time I believe the process to be beneficial, I should much prefer boiling to sterilization or Pasteurization, for the reason that I believe that in this way the destruction of morbific bacteria will be more completely effected, and also that changes of a protective nature will be produced in the dead bacteria and ptomaines with which the milk is loaded after sterilization In this suggestion I feel that I am supported by the experience of Professor Jacobi, who, after saying, "virtually sterilization" (that is to say by means of boiling) "has been practiced by me these more than forty years, and has been taught by me these thirty-five years both in lectures and in books and essays," adds "I always urged that safety increased with the number of boilings ' No doubt he was led to give this advice in consequence of carefully observed results of the benefits following repeated boiling as compared with a single boiling And this leads me to say in conclusion that the great danger of modern medicine appears to me to be the tendency to push theories to an extreme, and to disregard the teachings of experience No better proof of the existence of this tendency could be advanced than is found in Professor Jacobi s allusion to the advantage of the admixture of cereals for the purpose of finally dividing and suspending the casein of cow s milk in preparing it for digestion by the infant stomach As we well know it is not many years since we were assured in most positive terms that it was utterly impossible for a young infant to digest farinaceous food at all, and our theoretical teachers instructed us to banish it entirely from the infant ietary He calls attention to the fact that the researches Schiffer, Korowin and Zweifel have experimentally proved diametric contradiction to the statements of previous experimentalists, that a certain amount of starch can be digested by the saliva and pancreatic juice of young infants, and that Heubner of Berlin recommends in intestinal diseases of the very young the simplest flours, mainly of rice and oats, which have a finer microscopical structure than wheat "Practical experience, ' says Heubner, "surpasses theoretical conclusions

Jacobi in a foot note ventures the prediction that "before long more than to day it will be a generally accepted axiom that cereals must be given to make teeth when milk food alone does not suffice for their development

My own advice to mothers unfortunately compelled to nourish their infants artificially, if they are able to obtain pure milk, from cows of authenticated good health, and from dairies where proper sanitary precautions are known to be taken and are able to use the milk within twelve hours after milking and after very limited transportation, is that they should keep the milk in hermetically sealed jars and in a cool temperature, but should not subject it to Pasteurization, sterilization or boiling Under other conditions namely those of protracted transportation, prolonged exposure to high temperature, ignorance of the conditions of health of the cow or of cleanliness of the dairy, they should resort to boiling in preference to sterilization or Pasteurization It is possible that the boiled milk will tend somewhat more to induce constipation than will the sterilized milk, but this is a trifling objection which can easily be met

Benjamin Lee, M D

Successful Implantation of Teeth

Alma, Mich, Dec 18, 1895

To the Editor —My little daughter, aged 2 years and nine months, fell headlong down the cellar stairs and struck the two upper middle incisors on the edge of the step, extracting them as completely as if by forceps The alveolar processes of the right tooth were fractured and the gum lacerated the entire length of the root After the fright and the crying, which continued a half hour or more, the child was rocked to sleep in her mother's arms and placed in her buggy We found the teeth on the cellar steps uninjured They were placed in a normal saline solution of tepid temperature On the arrival of an assistant with the chloroform for anesthesia, the child was sleeping quietly Chloroform was administered without the child awakening and the teeth were placed within their sockets and pressed into position, the edge of each tooth fitting firmly in a groove of one blade of a forceps, the hand of the operator being placed on the back of the head with the pressure properly directed The gums about were cleansed antiseptically and the teeth left in position without further dressing or application

The accident occurred about 2 o'clock and when the child awoke from her sleep at 5 30, her teeth were in place The teeth had been out of the mouth fully one hour Milk and soft food were administered and the lacerated edges of the gums cleansed after the eating Healing of the gums occurred by first intention

It is now over four weeks since the teeth were placed and they are now solid, in good position and of normal color The gums are normal in color and consistency and the appearance of the mouth quite natural

I report this as a successful case of transplantation of teeth that had been out of the mouth over an hour and as another demonstration of chloroform anesthesia during natural sleep

E S Pettyjohn, M D
Medical Superintendent

It Was Hot Springs

Tennessee State Board of Health, Nashville, Dec 20, 1895

To the Editor —On page 1000, December 7, Journal of the American Medical Association, second column, line 10 (from bottom), "Little Rock ' should read "Hot Springs Much fault is found with me because of this error It is proper to state that I read no paper, only said a few sentences in a conversational way No proof of the proceedings was sent me, as should have been done The error is doubtless that of the reporter You know too well how these things happen Please make necessary correction, and oblige,

Very respectfully,
J Berrien Lindsley, M D
Secretary and Executive Officer

Defense of Hypnotism

Cleveland, Ohio, Dec 20, 1895

To the Editor —I have read with much surprise the note to you from Dr W P Howle, Oran, Mo, published in the issue of the Journal of December 14, in which he condemns hypnotism, along with the fallacies of clairvoyance, faith cure, etc, which intelligent men know to be frauds But, Doctor, in the light of my extensive experience in regular practice, where I have hypnotized 1,000 cases never once having failed to produce hypnosis where I made the attempt, I must protest against such indiscriminate and uncalled for condemnation of a great remedy in many cases which can not be rationally or successfully treated by other means If you are ready for it I will prepare a paper for your next issue, dissecting this remarkable set of statements Kindly advise me

Truly, M Maurice Carnes, M D

Papers for the Surgical Section

South Bethlehem, Pa , Dec 18, 1895

To the Editor —As Secretary of the Surgical Section of the Association, I am now engaged in arranging a program for the Atlanta meeting We have selected "The Surgery of the Cerebro spinal Axis and its Bony Encasement, as the special subject for discussion I am anxious to obtain as full and as representative a discussion on this important subject as practicable Will you permit me through the Journal to call the attention of our surgical members to this subject, and to request from them a liberal contribution of papers, and careful preparation for discussing the subject Besides this special subject there will be room on the program for papers on other subjects I solicit the active assistance and contribution of the members Members who desire to contribute papers to the Surgical Section will please notify me and send the title of their papers to me as soon as practicable Very truly yours,

W L Estes

International Scientific Language

Chicago, Dec 21, 1895

To the Editor —I have read with great interest your address on "The International Scientific Language' in the Journal of this date The position taken with regard to French seems to be good although as a matter of fact, Spanish is an easier language even than French and is now used by a greater number of people than any other language excepting English

Would it not be well, as a means of familiarizing the profession at large, in this country, with one of these languages, to have a page or two of the contents of the Journal, each week in the proposed International language?

Very truly yours,

W S Christopher

BOOK NOTICES

State Charities Aid Association of New York Handbook for Hospitals By Abby Howland Woolsey Third Edition 12mo, pp 267 New York and London G P Putnam's Sons, Chicago The W T Keener Co 1895

The first edition of this Handbook was published by the Association in 1877 and the second edition in 1883 No recent work having been found that would supply its place the managers of the Association appointed a committee to revise it, Miss Woolsey having died since the appearance of the edition of 1883

This committee consisted of Drs Charles Hitchcock, George G Wheelock and W Gill Wylie

"Not often,' say the committee, "has a work so easy or so grateful been assigned to any committee Twelve years have elapsed since the publication was last revised by the author, and yet the work done was so thorough, the personal knowledge of the subject so exceptional, and the standard of excellence so high that, beyond the bringing of statistics up to date, and the addition of some footnotes to show the advance, within a very few years, of hygienic requirements, there were but few alterations to be made"

We have been familiar with the former editions of the book, and we concur in the opinion of the committee that "every commissioner of charities and superintendent of the poor, every superintendent of a hospital, will welcome the many practical suggestions to be found in this volume It should be in the hands of all visitors to hospitals and other charitable institutions and on the shelves of every library in this country"

Twenty-Sixth Annual Report of the State Board of Health of Massachusetts 8vo, paper, pp 892 Boston 1895

The reports of the Massachusetts State Board of Health are without doubt the most valuable sanitary publications in the country, and they afford not only an *object* lesson for other State Boards, but they demonstrate the enlightened character of the legislation under which they are produced In another column we refer to one important inquiry in which the Board has been engaged, but it would be quite within bounds to say that within the pages of the twenty-six volumes are included luminous discussions of nearly every topic of hygiene that is of interest to the municipal sanitarian The present volume is of exceptional interest

Practical Uranalysis and Urinary Diagnosis A Manual for the Use of Physicians, Surgeons, and Students By Charles W Purdy, M D , Queen's University, Fellow of the Royal College of Physicians and Surgeons, Kingston , Professor of Urology and Urinary Diagnosis at the Chicago Post Graduate Medical School Author of "Bright's Disease and Allied Affections of the Kidneys' , also of "Diabetes Its Causes Symptoms, and Treatment ' Second revised edition With numerous Illustrations, including Photo Engravings and Colored Plates In one crown octavo volume, *360 pages, in extra cloth, $2 50 net* Philadelphia The F A Davis Co , Publishers, 1914 and 1916 Cherry Street Chicago office, Lakeside Building

In our notice of the first edition of this work (Nov 24, 1894, p 805) we said, "To the practitioner and as well to the clinician, this book must prove invaluble for the extent of information contained in its pages, and its practical character The author has "corrected all discovered errors' in the first edition, has revised it and has added several illustrations The early call for a new edition is a tribute to its scientific accuracy, and we congratulate the author on the merited appreciation of the book by the profession

Pregnancy, Labor and the Puerperal State By Egbert H Grandin, M D , Consulting surgeon to the New York Maternity Hospital Consulting Gynecologist to the French Hospital, New York , etc and George W Jarman, M D , Obstetric Surgeon to the New York Maternity Hospital, Gyecologist to the Cancer Hospital, New York, etc Illustrated with forty-one original full-page photographic plates from nature Royal octavo, pages viii, 261 Cloth, $2 50 net Philadelphia The F A Davis Co , Publishers, 1914 and 1916 Cherry Street Chicago office, Lakeside Building

This work, say the authors in the preface, aims at being a guide to practice and is clinical in its teaching There are three parts, of which one is given to pregnancy, containing three chapters, the second to labor, containing four chapters, and the third, on the puerperal state, is disposed of in two chapters The photographs are excellent and the text instructive It is a faithful representation of the modern practice of obstetrics

Ohio State Medical Society —Transactions of the Semi-Centennial meeting held at Columbus, May 15, 16 and 17, 1895

This volume shows that the society is keeping up to its usual high standard of work There are valuable papers on diphtheria, influenza, autopsies, intestinal surgery, typhoid fever, leprosy, and these papers are discussed in an able manner Appended is a copy of the Mosworth Bill to regulate the practice of medicine, which the society indorsed, and which has also received the *indorsement* of the Ohio State Eclectic Society and the Ohio State Homeopathic Medical Society The whole profession is in support of this bill, and as there are eighty physicians in the House of Representatives, it is confidently expected the bill will *become* a law The society is to be congratulated on its good work, its vigorous life at 50 years and its chances for the future

Lectures on Appendicitis and Notes on Other Subjects By Robert T Morris, A M , M D Illustrated 8vo, cloth pp 163 New York and London G P Putnam's Sons 1895

The first eighty-three pages of this book are given up t the lectures on appendicitis, and the remainder to notes o various surgical topics, mainly reports of interesting cas They all show excellent surgery The illustrations of th vermiform appendix in the first section of the work could no well be improved upon

Announcements

"The College and Clinical Record" will be hereaf known under the name of *Dunglison's College and Clin Record*, a Monthly Record of Practical Medicine'

The *American Medical Review*, edited by Dr Daniel Lewis and Dr George B Bradley, and published in New York, made its first appearance last week

The *Medical News* of Philadelphia will be edited and published in New York after January 1, 1896

PUBLIC HEALTH

Typhoid Fever in Ohio.

Ohio State Board of Health Office of the Secretary
Columbus, Ohio, Dec 21, 1895

To the Editor —Owing to absence your letter of the 17th just received I returned from the smallpox district yesterday and am going back there again to day In Bridgeport and immediate vicinity there were up to yesterday morning twenty-eight cases At Martin's Ferry, which is a separate corporation but practically the same community, there were forty-eight cases There is one case at East Liverpool and one case at Lisbon These two latter cases contracted the disease at Martin's Ferry The disease was not introduced by emigrants, but is due to a negro having smallpox who was landed at Wheeling early last fall

The disease was started in Wheeling and ran several months, but has been suppressed there It crossed the river to Bridgeport and Martin's Ferry, which are in Ohio opposite Wheeling and connected by street car lines Our Board has now put in force proper regulations for preventing further spread of the disease, and these are being strictly carried out General vaccination is being carried out by house to house visitation by physicians I confidently expect that the disease will soon be under control

Yours truly, C O Probst, Sec'y

The New York City Board of Health —The Board of Estimate of the City of New York has appropriated $519,508 for the Health Department's operations in 1896, which is an increase of $59,000 as compared with the current appropriation This increase is, partly at least, believed to be rendered necessary by reason of the new and expensive work done by the Bacteriologic Bureau, in the production of anti diphtheritic serum

Typhoid in Wisconsin —At a meeting of the State Board of Health of Wisconsin December 19, a statement was made that the number of cases of typhoid fever reported to the Board since July 1 throughout the State was 625, of which 133 were reported in Milwaukee, 115 in Superior, seventy-four in Shell Lake, fifty-two in Ashland and twenty-four in La Crosse The causes of the prevalence of the fever were invariably due to the use of contaminated water Plans were submitted for the proper filtration of Ashland's water supply, and a committee of the Board will go to that city to look into the matter

Health Reports —The following health reports have been received by the Supervising Surgeon-General Marine-Hospital Service

SMALLPOX—UNITED STATES

Michigan Dec 7 to 14, Detroit, Park Township and Rochester, smallpox reported
New Orleans, Dec 7 to 14, 11 cases, 2 deaths
Tennessee Shelby County, Nov 15 to Dec 15, 15 cases, Memphis, Nov 29 to Dec 13, 13 cases, Ashport, Dec 2, 1 case, Alamo, Dec 2, 2 cases

SMALLPOX—FOREIGN

Rio de Janeiro, Nov 9 to 16, 58 deaths, Nov 16 to 23, 49 deaths
Havana, Dec 5 to 12, 1 death
London, Dec 1 to 7, 1 death
Dublin, Dec 1 to 7, 5 cases, 1 death
Corunna, Oct 1 to 31, 3 deaths, Nov 1 to 30, 5 deaths
Constantinople, Aug 1 to 31, 14 deaths
Madrid, Nov 10 to Dec, 3, 12 deaths
Odessa, Nov 23 to 30, 3 cases, 2 deaths
Pernambuco, Nov 2 to 16, 108 cases, 28 deaths
Prague, Nov 23 to 30, 19 cases
Rotterdam, Dec 1 to 7, 1 death

CHOLERA—FOREIGN

India Bombay, Nov 12 to 19, 9 deaths, Calcutta, Nov 2 to 9, 47 deaths
Japan, to Nov 14, 56,367 cases, 39,721 deaths

YELLOW FEVER—FOREIGN

Rio de Janeiro, Nov 9 to 16, 7 deaths, Nov 16 to 23 18 deaths
Havana, Dec 5 to 12, 6 deaths
Pernambuco, Nov 2 to 16, 12 cases, 4 deaths
Santiago de Cuba, Dec 1 to 7, 20 deaths

MISCELLANY

It was the College of Pharmacy —We printed last week a press dispatch in regard to a conference with the Board of Trustees of the University of Illinois, with five members of the Chicago College of Physicians and Surgeons The item was in error The conference was held by representatives of the Chicago College of Pharmacy

The Mary Thompson Hospital of Chicago for Women and Children —Dr Marie J Mergler, Professor of Gynecology and Clinical Gynecology, Northwestern University Woman's Medical School, has been appointed Gynecologist and Head Physician and Surgeon to fill the vacancy caused by the lamented death of Dr Mary Harris Thompson In memory of the valued services of the deceased physician the name of the hospital has been changed from "The Chicago Hospital for Women and Children" to the above The hospital extends the privilege of bringing patients from all parts of the country and retaining the care of them, to physicians in good standing other than those of the medical staff Dr. Mergler holds the position of gynecologist to the Wesley Hospital and the Post-Graduate School and is also surgeon to the Woman's Hospital of Chicago

New Provision for Care of Oklahoma Insane —Section 2,990, paragraph 1, chapter 42, of the Oklahoma Statutes authorizing the Governor of the Territory to contract with any Territory or State in the United States, or with the proper authorities thereof, for the care of persons who become insane within the Territory, and who are citizens thereof, such care to be had in the insane asylums of the Territory or State with which such contract may be made, has been amended so that it is now, in substance, as follows The Governor is authorized and directed to enter into a contract with responsible individuals or private corporations for the treatment, care and maintenance within the Teritorry, of of the Territory's insane, and of all persons who become insane within the Territory, and who are citizens thereof, for a term not to exceed three years from on or before June 15, 1895, and at a rate not to exceed $300 per annum for each patient, *Provided*, That the contract shall stipulate that the regulations prescribed by law of the States of Illinois or Kansas for the treatment of the insane, shall be those governing the contractors in the care and treatment of the insane, as far as the same can be made applicable, *Provided, also*, That burial expense and accounts for conveying discharged patients to their residence shall be a county charge The Governor, it is also enacted in this connection, shall also have power under this act to contract for the deaf and dumb of the Territory, by parties within or without the Territory, in like manner as provided in this act for the care of the insane

Tablets of Quinin Not Approved —The conservative editor of the *Practitioner* offers a very original, not to say unpopular, notion that quinin be taken in effervescent solution The writer seems to have had a better experience with pills than with tablets He says, "It will frequently be found that if prescribed in a liquid effervescent form, quinin will agree well with the stomach As a prophylactic remedy, basic hydrochlorate of quinin is less irritating than the sulphate and more pleasant to take on account of the absence of the extremely bitter taste characteristic of the latter The dose can be carefully regulated, and it contains a proportionately larger quantity of quinin than the sulphate It is easily transported, and keeps perfect Hydrobromate of quinin, it seems, ought to be employed particularly for the treatment of obstinate fevers, in which the hydrochlorate has failed to produce the desired effect Quinin salts should not be put up in the form of tablets, as repeated examinations of samples from various sources have proved that they are either too brittle or completely insoluble After having administered such tablets to rabbits, the investigators found them two hours later to be entirely unaffected by the gastric juice Better results were obtained with gelatin capsules and medicinal pearls, which readily dissolved in slightly acid solutions or in the stomach of the rabbit The advantage of these preparations is the ease of controlling their composition and their small size Pills, contrarily to the prevailing opinion, gave the most prompt and invariable results, even when silver-coated pills, which had been kept upward of a year, were used Pills of pearls, containing 15 centigrams of quinin hydrochlorate, may be administered for prophylactic purposes—two daily, in a little water"

No Public Money for Private Hospitals —A hospital founded by a private benefactor is, in point of law, a private corporation, although dedicated by its charter to general charity When the corporation is said at the bar to be public, it is not merely meant that the whole community may be the proper subjects of the bounty, but that the government have the sole right, as trustees of the public interests, to regulate, control and direct the corporation, its funds and its franchises, at their own good will and pleasure These statements of the Supreme Court of Illinois in the case of the Washingtonian Home of Chicago v City of Chicago, decided October 11, 1895, furnish the key to its holding that the Washingtonian Home, which was incorporated as an institution for the care, cure and reclamation of inebriates, with power to elect its own directors and adopt such by laws as it thinks proper, but subject to no State, county or city control, is nothing more than a private corporation The act under which this institution was incorporated provided that it should receive ten per cent of all money paid for all licenses granted by the county or city for the right or privilege to sell spirituous vinous or fermented liquors in the county or city, and it was to compel the city of Chicago to pay it $25 000 thereunder that this suit was brought But conceding that this was a constitutional provision in 1867, the Supreme Court holds that it was rendered void by a clause in the State constitution of 1870 declaring that no county, city, town, etc , shall ever become subscriber to the capital stock of any railroad or private corporation or make donation to or loan its credit to any such corporation The fact that the city has for over twenty years made the payments after the adoption of the constitution, the court further holds, does not estop it from claiming the unconstitutionality of the act under which they are demanded

Contracts Not to Practice Medicine —It has come to be settled law that the mere sale of the goods, stock in trade and good will attached, without any express stipulation not to resume or engage in the business in that locality on the part of the seller, are not sufficient to warrant a court of equity in restraining the seller from again engaging in such business in the same locality And in such case it is to be noted that the sale necessarily puts an end to the business of the seller, at least for the time being But a sale by a physician of his residence, for example, need cause no interruption of his business, and therefore it would seem to be the conclusion of the Supreme Court of Indiana that in the latter case by so much the more will there be no interference to protect the purchaser aside from what he may be entitled to under an express contract In the case of Beatty v Coble, which that court decided Oct 18, 1895 a practicing physician contracted, in consideration of the purchase of his property, to " retire from the practice of medicine and surgery" at the place named The court holds that this contract must be construed or interpreted from the language employed therein, and from the circumstances surrounding the contracting parties, and thus get at their intention as expressed in the instrument In this way its plain meaning and import is found to be that the selling party agreed not to engage in the practice in that field, without limitation as to time His contention that a good faith retirement for a year and a half was a sufficient compliance, the court does not agree with It holds that the want of definite limit is no objection to the contract And it is a contract which will be enforced by injunction The adequacy of the consideration will not be inquired into Nor is a want of consideration shown in the fact that, at the time of making the contract, the physician was not owner of the property sold but it was the sole and separate property of his wife which was built for and used as a residence, and not as a physician's office, and no part of the consideration for the conveyance thereof was ever received by him, and no consideration ever passed between the purchaser of the property and him for the execution of the agreement sued on That, pending the appeal to the Supreme Court, he located in another town, the court also holds is no ground for dismissing the case, his practice reaching into portions of the county which constituted his former field of labor

Declarations to Physician —The declarations of a patient to his physician respecting his condition and symptoms at the time of seeking medical aid are admissible as evidence in his behalf, under a well settled exception to the rule excluding "hearsay" The exception originally rested on the ground, first, that as the common law forbade parties testifying, the facts involved could not not be proved in any other way, and second, that the patient's interest in the physician's opinion precluded danger of falsehood The modern practice of admitting parties as witnesses has removed the first of these grounds, but this is not considered a sufficient reason for excluding the testimony To render it admissible, however, the plaintiff must establish the fact on which the exception rests—that is that the declarations were made when seeking medical aid So says the United States Circuit Court of Appeals in the case of Del , L & W Ry Co v Roalefs, decided Oct 28, 1895 This was an action brought to recover compensation for personal injuries sustained in a railroad accident The only contest was over the amount due The plaintiff called as a witness a physician of great reputation as a medical expert, who had examined him professionally a year after the accident, when his condition was much improved, and asked him to state the former's declarations at the time respecting his condition and symptoms past and present, together with his own opinion based on these declarations and the personal observations made This testimony the court holds should have been excluded because the inference was irresistible that the plaintiff did not call to consult the doctor with a view to medical aid, but to employ and qualify him as an expert to assist in maintaining the pending suit Still the court holds that the doctor's opinion might have been taken hypothetically—based on his observations and the facts embraced in the plaintiff's statements Whether the admissions of such opinion should follow or precede proof of the supposed facts would have been a matter of discretion , but until the facts were proved the opinion could not be considered, and if its admission preceded the proof it should have been ruled out if the proof did not follow The opinion being inadmissible, nothing indicating how much it rested on the declarations and how much on personal observation, it must be accepted or rejected as a whole

Practical Notes

The Aluminum Corset —Dr Phelps, of New York City, recently addressed the Academy of Medicine on the merits of the various materials used in spinal disease In lateral curvature, the jacket of aluminum was, so far as he had tested it, freer from objections than the others, but it was somewhat expensive, costing fifty dollars or more A plaster corset was first made, the patient being suspended , this filled with plaster, and over the latter the aluminum cc was hammered into shape It had numerous perforatio smaller than a dime The weight of the apparatus is a two pounds If the patient changed much in shape and it would be necessary to make a new corset

Bacteriologic Examination of Nine Cases of Diphtheria Treated with Antitoxin —Stokes (*Boston Medical and Surgical Journal* cxxxii, No 24) describes briefly the results of the bacteriologic examination of nine fatal uncomplicated cases of diphtheria treated with the antitoxin The examination consisted in making slants upon blood serum from the lung, liver, spleen, kidney and the heart s blood In five cases the streptococcus was found in the liver, spleen, kidney and heart s blood, in one case in kidney and heart s blood, in one case in the spleen The pneumococcus was found twice in the kidney and in one of these the streptococcus was present in the spleen In one case the only organism present was the bacillus coli communis In the lungs of all these cases were found the bacillus diphtheriæ, streptococci, pneumococci, and staphylococcus pyogenes aureus, either alone or in various combinations The bacillus diphtheriæ was found in the kidney in four cases, once in the heart and once in the spleen The presence of these various organisms in addition to the bacillus of diphtheria enables one to understand the fatal issue in spite of the antitoxin administered, because this agent can not be assured to act against any other microorganism than the bacillus of diphtheria Assuming, the efficacy of this remedy to be greater, the earlier it is administered, it can not be too greatly emphasized that its thorough, early introduction may lessen the dangers of a secondary infection because it places the system in a better condition to overcome the various ill effects of various complicating bacteria that may be present in the body

Condyloma of the Trachea —Dr Harrison Griffin, of New York City, has reported in the *Medical Journal*, of that city, an instructive case of condylomata of the trachea The patient, a female aged 40 years, sought medical relief on account of a dryness and irritation in her throat, with a tickling cough, occasional great difficulty of breathing, which increased at times without any assignable cause, patient's voice was weak and hoarse, the breath fetid, and the respiratory movements labored during both sleeping and waking hours The slightest cold would develop a paroxysm of dyspnea There was a history of pudendal chancre about eight years ago An examination of her mouth, nose, and postnasal space was negative, an examination of her larynx showed the mucous membrane to be free from any congestion or ulceration

A view of the trachea during the act of inspiration showed a large projecting and granular growth, red in color and covered with a pultaceous secretion, the growth was irregular on its surface and separated by fissures, their edges being abrupt and sharp

The projecting mass was attached more to the anterior portion of the trachea and extended around two-thirds It seemed to be situated only a short distance below the vocal cord and extended down on the trachea to the distance of about an inch The lumen of the trachea was very much diminished The examination by the laryngoscope was made with great difficulty owing to the patient being very nervous The condition of the larynx and her unusual shortness of breath pointed to an immediate tracheotomy, but this was deferred as a last expedient The patient was given large doses of potassium iodid (1 drachm four times a day), and unguentum hydragyri oxidi rubri was ordered to be rubbed in over the thyroid cartilage The case was seen daily for three weeks when she was discharged with the parts completely healed, but warned her to continue medicine for a certain space of time

An examination with the laryngoscope at this period showed but slight narrowing of the trachea at the point of the syphilitic affection Her breathing was normal and the swelling of the neck subsided as she came under the influence of the iodid She was now able to lie prone in bed and and all attacks of dyspnea subsided

The rarity of these cases is indicated by the statement of Sir Morrell MacKenzie, that he had met with three cases only among 1,145 cases of syphilis of the region of the larynx and pharynx

Detroit Notes

Paper on Croupous Pneumonia —The Detroit Medical and Library Association at its regular meeting, December 16, listened to an instructive paper by Dr D S Campbell on "Croupous Pneumonia" The Doctor said, "My paper is on the present management and treatment of croupous pneumonia, based on the fact that it is a specific or constitutional disease, similar to that of typhoid fever, etc, that it will run a natural course and can not be abated by any mechanical or therapeutic measure, also that the ever constant symptom of greatest importance is the excessive temperature which is independent of the local manifestations in the lung About 80 per cent of croupous pneumonia cases do not require anything but good nursing and care but that the remaining 20 per cent—those who are attacked with it very seriously and from the out-set with perhaps several rigors, denoting its approaching malignant type and impending excessive fever—require active measures toward holding this latter symptom in abeyance, which if continued for a day or two, would tend to produce cardiac insufficiency, the other organ which is most dependent on its effection. The treatment for this is laid down from actual experience, and was best *carried out* by the use of cold applications, or the bath commencing at 90 degrees, gradually reduced to about 65 the patient to remain in it from thirty to forty minutes as the case demanded, and if any reaction resulted they were given freely whisky or brandy in modern doses, but from my experience the excessive fever should be reduced from one-half to two and one half degrees If pain was present in the onset I employed hypodermic injections of morphia with atropia in their usual doses, and chloral hydrate if the patient required it from want of sleep or restlessness"

Dr Christian F Kapp's suit against George Hermindinger as noted in the last number of the Journal, in which the Doctor sought to recover $15,000, for making 372 calls and furnishing the medicine upon smallpox cases, Mr and Mrs Hermindinger with *their children* being the patients, resulted in a verdict for the Doctor for $400 One practicing physician in testifying said $2 was enough for visiting a smallpox patient This suit was tried by a Washtenaw County jury in Ann Arbor Health office report for week ending Dec 21, 1895 Deaths *under 5 years*, 22, *total* 85, births, male 41, female 49, *total* 90 Contagious diseases Diphtheria Last report 40, new cases 36, recovered 36, died 7, now sick 33 Scarlet fever Last report 25, new cases 3, recovered 6, died 1, now sick 21 Smallpox Last report 3, new cases none, recovered none, died *none, now sick* 3

St Louis Notes.

Reports of the Health Office —For the week ending December 14, the total number of deaths from all causes was 170 as compared with 159 for the preceding week, and 154 for the corresponding period of 1894 Births reported, 204 Report for the week ending December 21 Total number of deaths from all causes, 167, in corresponding period of 1894, 145 Contagious diseases reported during the week ending December 14 Diphtheria, 111 cases, 9 deaths, croup, 14 cases, 8 deaths, whooping cough, 4 cases, one death, measles, 9 cases, typhoid fever, 6 cases, scarlatina, 7 cases During the week ending Decemper 21, Diphtheria, 87 cases, 10 deaths, croup, 14 cases, 5 deaths, typhoid fever, 14 cases, 1 death, whooping cough, 1 case, scarlatina, 16 cases

St Louis Medical Society —The meeting December 14 was the occasion of a change of program and an extension of courtesy to Dr B Sachs, of New York, who read a paper on "Syphilis of the Spinal Cord" The meeting on December 21 was notable as the occasion of the presentation to the society, by Dr Warren B Outten, of a portrait in oil of the late Dr Charles A Pope The portrait is the product of Dr Outten's artistic talent and was presented by him in a very happy speech One of the Nestors of the society, Dr William M McPheeters, responded on behalf of the society in a speech of acceptance Dr Pope was well known as the first Dean of the St Louis Medical College, and his life and work exercised a marked influence upon the medical thought and practice of St Louis, and more widely through numerous students

t

Reminiscences of his life were related during the evening by Dr Pollak and others of his immediate contemporaries

The Clinico-Pathological Society —This society was organized in November with an initial membership of twenty The executive board is constituted by Drs James A Close, Hugo Summa, H J Cummings, A J Bock, and C G Chaddock, Secretary The meetings are held on the second and fourth Mondays of each month At the meeting December Dr B M Hypes read an important paper on "The Use of Intra Uterine Injections of Glycerin for the Induction of Labor" The paper and discussions overwhelmingly condemned the use of glycerin for such a purpose because of the unavoidable dangers attending it The paper was based on a fatality following the injection of glycerin, and written anent favorable reports of its utility that have recently appeared in literature The remainder of the evening was devoted to the discussion of pathologic specimens and cases, in particular the case of a death in chloroform narcosis presented by Dr Summa, where the kidneys were found to be in an advanced stage of cirrhosis The question raised for discussion was what should be the criterion of contra indication for the use of chloroform in such cases It was pointed out that not the simpler urinary indications should be the guide, but rather the indications to be gained from an exact quantitative estimate of the excretion of urea The program announced for the meeting December 23, includes a paper on "The General Medical Relations of Uranalysis" by Dr Hugo Summa and "A Case of Cerebral Tumor, with Specimen," to be discussed in its diagnostic and surgical relations, by Dr C G Chaddock The program for the first meeting in January includes a paper by Dr J A Close entitled "What Amount of Work in Bacteriology should the General Practitioner be able to Perform?"

Louisville Notes

Petition —The women of the State are circulating a petition among themselves which they will present Governor Bradley requesting that he appoint only married men as resident physicians at the various insane asylums in the State It is an assured fact that the governor will not countenance any such reflection on the prominent physicians of the State whose names have been mentioned in connection with the appointments

Irregular Practitioners —Dr J N McCormack, Secretary of the State Board of Health, has issued a circular letter, under date of Dec 16, to all county medical referees, calling their attention to the fact that a number of so-called doctors" from the advertising "medical companies" of Indianapolis, Cincinnati and Chicago, are plying their trade in the outlying districts of the State They accept fees, in negotiable notes, payable at some point outside of the State These are promptly discounted, and in this way thousands of dollars have been extorted from families who can the least afford such a loss One conviction has been obtained in Grant County and warrants are out for others The referees are admonished to be on the lookout for them and to report to Dr McCormack

Academy of Medicine —At the regular meeting of the Academy on Monday evening Dec 16, Dr I N Bloom read the paper, on "An Historic Sketch of the Etiology of Chanroids" The Academy voted to give up their present quarters in the Fonda Block, and will move to the Louisville College of Pharmacy building, corner First and Chestnut streets, where they will be at very much less expense

Deaf Mutes —Superintendent J E Ray of the Kentucky Institution for the Education of Deaf Mutes, located in Danville Ky, has just made his report to the governor, extending over a period of two years It shows that for the year ending Oct 31, 1894, the expenditures for all purposes amounted to $41,709 55, or a per capita expense of only $164 For the year ending Oct 31, 1895 with 835 pupils enrolled against an enrollment of 225 the previous year, the expenditures aggregated $49,267.29, or a per capita expense of less than $147 This is a most successful work

Surgeon General —Dr J F Kimbly, of Owensboro, has been appointed Surgeon General of the State Guard with rank of colonel Dr Kimbly is a prominent republican and made the race for Congress in 1892, being defeated by W T Ellis

Rubey —William Rubey, who has been illegally practicing medicine in this city, was arrested at the instance of the State Board of Health, tried in the City Court and fined $100, having been previously convicted and fined in the Boyle County Court for the same offense The testimony of the two witnesses showed that Rubey claimed to cure by the laying on of hands" and administering a "kidney tonic," receiving in the case of one witness compensation therefor

Health Ordinances —The upper Board of the Common Council has passed the health ordinances drawn up and presented by the health officer, Dr White, and await now the signature of the Mayor These are very comprehensive laws and provide for the notification of the health office of contagious diseases and the proper placarding of houses in which the cases are, the control of funerals of those dead from contagious diseases, the care of smallpox cases, the vaccination of school children and all persons exposed to smallpox, and the abatement of sanitary nuisances There has been a general cut of all city officials salaries, and Dr White's has been reduced to $1 800 from $2,000, and his clerk has been removed This is greatly to be regretted, as the added work on account of the recently passed ordinances makes a clerk indispensable to the proper conduct of the health department

License —It is greatly to be regretted that the excellent work of the new Common Council recently elected in reducing the city expenses should be marred in its efforts to obtain revenue, by adding an additional sum to the license required of practicing physicians. The license required at present is $10 per year, and it was recently raised to $15

Deaths —The weekly death report shows a total of sixty one deaths, forty five white, sixteen colored Pneumonia caused four deaths, consumption six, typhoid fever four and diphtheria three

Washington Notes

Weekly Report of the Health Officer —The report of the Health Officer for the week ending Nov 30 is as follows Number of deaths (still-births not included) White, 66, colored, 44, total, 100 Death rate per 1,000 per annum White, 18 8, colored, 23 8, total, 23 8 Death rate per 1,000 per annum corresponding week last year, 14.2 The deaths reported at the Health Department during the past week numbered 110 The mortality for the week previous was 86 The increase is mainly due to brain, lung and kidney diseases, the deaths from the latter malady numbering 10, and those from lung troubles reaching 27 Nearly one-fourth of all the persons who died were under 5 years of age Forty of the decedents were over fifty years old There were 6 deaths imputed to typhoid fever, 3 were from diphtheria and 1 from scarlet fever The deaths from violence numbered 5, of which 2 were suicides Hospitals reported 21 and the coroner 10 deaths Marriages reported were 41, and births returned were 107 and still births 14

Officers of the Foundlings' Hospital —At a meeting of the Board of Directors of the Washington Hospital for Foundlings held December 16, the following were chosen as officers of the Board of Lady Visitors Mrs W P Kellogg, President, Mrs S W Cullom, Mrs M C Stone, Mrs Charles G Dulin, Mrs F E Warren and Mrs J N Whitney, Vice-Presidents, and Mrs C B Beall Secretary

Dental Society Elects Officers —At the twenty-ninth annual banquet of the Washington City Dental Society, held December 19, Dr A W Sweeney read the annual address and Dr L C F Hugo officialed as toastmaster Officers for the ensuing year were elected as follows Dr William M Hunt, President, Dr D E Wilbur, Vice-President Dr W N Cogan, Secretary, Dr M F Finley, Treasurer, Dr N H B Noble, Librarian, and Dr Garnett L Hills, Essayist

Hospital Directors Appointed —The Commissioners have appointed as Directors of the Columbia Hospital and Lying-in Asylum, to fill two vacancies, Surgeon General George M Sternberg, U S A, and John B Wright, Secretary of the Board of Trade Formerly the Directors filled all vacancies occurring in the Board, but Congress recently amended the charter of the hospital requiring the Commissioners of the District to fill all vacancies

Physician to the Poor Appointed —Dr A T Mitchell has been appointed physician to the poor, vice Dr J C Meredith, whose term has expired The Commissioners have accepted the resignation of Dr V B Jackson, resident physician at the Washington Asylum Hospital, and appointed Dr T B McDonald to fill the vacancy Dr McDonald was first assistant resident physician to the Emergency Hospital and resigned to accept the late appointment

Central Dispensary and Emergency Hospital —The competitive examinations held December 20 at the hospital, resulted in the selection of the following named physicians Dr B F McGrath, President, Dr Max Peralto, First Assistant, and Dr William E West, Second Assistant They enter upon their respective duties on January 1

Physicians Shall not Disclose Confidential Communications—Mr Morrill has introduced a bill in the Senate providing that in the courts of the District of Columbia no surgeon shall be permitted, without the consent of the person afflicted, to disclose any information which he shall have acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, whether such information shall have been obtained from the patient or his family, or from the person or persons in charge of him, provided that this act shall not apply to evidence in criminal cases where the accused is charged with causing the death, or inflicting injuries upon a human being, and the disclosure shall be required in the interest of public justice

Recommendation of the District Grand Jury —The Grand Jury has rendered a report on the prevalence of typhoid fever in the District "Although the conclusions set forth were reached two months ago, pressure of other business justified delay until now," says the report "It is useless to obscure facts Each successive year in the past twelve has practically added to the per capita number of typhoid cases in this District Statistics which are facts show the proportion greater than the situation and climatic conditions seem to warrant Our belief, based on scientific examination, is that Potomac water for drinking purposes at the present time is conducive to the germination of typhoid fever"

A system of sedimentation and filtration is primarily necessary, the grand jury thinks, also that the water supply should be increased, that as opportunity offers all pumps and wells should be closed, and that box privies be discontinued by law

"All improved premises abutting on public sewers and water mains" continues this report, "should be connected with such sewers and water mains, and their occupancy unless so connected prohibited by law"

Dr Busey's Presidential Address —At the meeting of the Society held on December 18, Dr Samuel C Busey read his presidential address for 1895, entitled "Compulsory Reports of Zymotic Diseases, Milk Legislation, Medical Practice Laws and Society Publication of Its Transactions" Seldom, if ever before, has this Society listened to so scientific and practical an array of facts and suggestions The Society tendered him a vote of thanks and ordered one thousand copies of the address printed for distribution The annual meeting for the election of officers will take place January 6, 1896, and the general sentiment is for his re-election

Washington Obstetrical and Gynecological Society —he 237th meeting of the Society was held December 20 Dr S S Adams reported a case of typhoid fever in a child 3 years of age, Dr Deale reported a case in which there was a large quantity of H_2S in the urine

Marine-Hospital Service Examinations

There will be held at Washington D C, on Feb 10, 1896, a competitive examination of candidates for appointment to the position of Assistant Surgeon in the United States Marine Hospital Service Candidates are required to be not less than 21 years of age, and no appointment is made of any candidate over 30 years of age They must be graduates of a reputable medical college and furnish testimonials as to character

Successful candidates, having made the required grade are appointed in order of merit as vacancies arise during the succeeding year There is at present one vacancy

A successful candidate when recommended for appointment is commissioned by the President of the United States as an Assistant Surgeon After four years of service and a second examination he is entitled to promotion to the grade of Passed Assistant Surgeon and to the rank of Surgeon, according to priority, on the occurrence of vacancies in that grade

The salary of an Assistant Surgeon is $1,600 per annum together with furnished quarters light and fuel that of a Passed Assistant Surgeon $1,800 and that of Surgeon $2,500 per annum In addition to the above salaries after five years' service, an additional compensation of 10 per cent of the annual salary for each five years of service is allowed medical officers above the rank of Assistant Surgeon the maximum rate, however, not to exceed 40 per cent When an officer is on duty at a station where there are no quarters furnished by the government compensation for quarters is allowed at the rate of $30 per month for an Assistant Surgeon $10 for a Passed Assistant Surgeon and $50 for a Surgeon The successful candidates after receiving appointments, are usually ordered to one of the larger stations for training in their duties Full information may be obtained by addressing the Surgeon General of the Marine Hospital Service, Washington D C
